MANNYNG, or MANNING, or DE BRUNNE, *Robert*, one of the English rhyming chroniclers who flourished at the end of the thirteenth and beginning of the fourteenth century, was born at Brunne, or Bourne, in Lincolnshire. He graduated at Cambridge, and lived as a Gilbertine canon, first at Semperingham, and afterwards at Sixhill, two priories in his native county. His first work was a free paraphrase into English rhyme of the *Manuel des Péchés* (Manual of Sins), a work of William de Wadington, in which the seven deadly sins are displayed in their most uninviting aspect by the aid of moral precepts and legendary tales. Another work of Mannyng was the *Medytaciuns of the Soper of our Lorde Jhesu, and also of his Passyun and eke of the Peynes of hys Swete Modyr Mayden Marye*, a metrical translation of Bonaventura's prose treatise *De Cœna et Passione Domini, et Pœnis S. Mariæ Virginis.* His chief translation, however, was his rhyming chronicle of England, in two parts. The former part, treating of that period of English history between the landing of the Trojans and the death of the Welsh Prince Cadwallader in 689, is translated from Wace's *Brut d'Angleterre*, and, like the original, is in the romance couplets of eight syllables. The latter part, which continues the history down to the death of Edward I., is taken from Peter de Langtoft's French Chronicle, and is translated into the Alexandrines of the original. This part has been published by Hearne under the title of *Peter Langtoft's Chronicle*, 2 vols. 8vo, Oxford, 1725. The first part is still in manuscript. Mannying gives indications in his works of untiring industry; but a facility in rhyming was the sole poetical faculty that he possessed. He is supposed by Hearne, but for no satisfactory reason, to be the author of the metrical romance of *Rycharde Cuer-de-Lyon.*

MANRESA, a town of Spain, capital of the partido of the same name in the province, and about 32 miles N.W. of the town of Barcelona. It lies on the left bank of the Cardonero, and about two miles above the junction of that river with the Llobregat. The Cardonero is crossed near the city by two bridges, one originally of Roman construction, and consisting of eight arches, the other of nine arches, erected in 1804. It is surrounded by walls, under which, on the bank of the Cardonero, is the only public promenade of the town. There are about 2300 houses of from three to five storeys, mostly well built, and the streets are causewayed and provided with covered sewers. The collegiate parish church, of semi-Gothic architecture, is capacious, and remarkable for a fine and lofty spire of bold construction, and for the fine sculpture and carving it contains. Also of good architecture is the ex-convent of Carmelites, which has some paintings of merit; that of the Dominicans has lost almost all trace of its primitive construction, and now serves as a barrack. There are several well-endowed and well-attended schools; an hospital under the care of the Sisters of Charity of St Vincent de Paul; and a female orphan asylum. The town is supplied with water from the Llobregat by an aqueduct 4 leagues in length, and by the wells, of which there are many within the walls. There are manufactories of cotton, cotton thread, silk ribands, earthenware, cutlery, leather, and superior brandy. The cotton factory is one of the largest in Spain. There are also saltpetre and gunpowder works. In the neighbourhood are quarries of building stone that might supply the whole kingdom, and coal has been discovered, but remains unworked. Manresa suffered much in the war of independence; in March 1811 it was almost completely burnt to the ground by Marshal Macdonald. The population in 1845 amounted to 13,339.

MANS, LE, a town in France, formerly capital of the province of Maine, and now of the department of Sarthe, is situated on the W. bank of the River Sarthe, 50 miles N.E. by N. of Angers, and 132 miles by railway S.W. of Paris. It is built on the slope of a hill near the confluence of the Sarthe and the Huisue, and consists of two parts, an old and a new town. The former is situated at the foot of the hill, and is irregularly built, with narrow, crooked, and for the most part dirty streets and lanes, but possessing many curious and interesting relics of ancient times, which are now fast disappearing. The new town is on a higher level, and is much better and more regularly built, having several fine streets and a spacious square called Place des Halles; but on the whole it is a dull and uninteresting place. There are also two good promenades,—Des Jacobins and Du Greffier, the latter of which extends along the banks of the Sarthe. Mans is chiefly remarkable for its ecclesiastical edifices, of which the principal is the cathedral of St Julien, comprising two styles of architecture, and dating from two if not more periods. The nave, which is believed to be of the twelfth century, is Romanesque, but it has pointed arches, while the side aisles and walls, and the west front, are at least as old as the eleventh century. The south doorway is richly carved, but much mutilated; while the choir is remarkably beautiful, and has very fine stained-glass windows. This church contains the tomb of Berengaria, queen of Richard I., and also the monument of Charles of Anjou, 1474, and of Langey du Bellay, distinguished as a warrior and author in the time of Francis I. and Henri II. The church of Notre Dame de la Coûture, has a very ancient choir, supposed to date from the tenth century, and of rude construction. The conventual buildings were formerly attached to the church, but these are now used for the prefecture, a museum of natural history and antiquities, and a library of 40,000 volumes. Besides these, there are also the churches of St Pierre and Notre Dame du Pré. The other chief buildings in Mans are the theatre, the theological and communal colleges, and the corn-market buildings. The manufactures of Mans consist of woollen stuffs, linen, lace, soap, paper, and leather. The commerce, which is considerable, is chiefly in these articles; and the products of the vicinity, such as iron, salt, wine, brandy, oil, corn, clover seed, cattle, pigs, poultry, &c. In the time of the Romans a town of the name of *Suindinum* stood here, and was the chief town in the district of the Cenimani. In the fourth century the town took the name of *Cenomania*, whence the present name. Its history, from the most remote period, is a series of disasters and devastations; and before the twelfth century it had been taken and pillaged twenty-six times. During the war of the League, Mans was besieged and obliged to surrender by Henri IV.; and in 1793 it was the scene of the destruction and final dispersion of the Vendéan army, when upwards of ten thousand persons were slaughtered. Pop. (1851) of the town, 24,568; of arrondissement, 173,102.

MANSAROWAR, or Mansahror, a lake situated on the northern side of the Himalaya Mountains, which divide Hindustan from Thibet and Tartary. It is considered by the Hindus as the most sacred of all the various places of pilgrimage, and they evince their zeal by the hardships and dangers which they endure in reaching it. It is also held in great veneration by the Tartars, who carry a portion of the ashes of their friends from a very great distance to be thrown into it. It is situated on an elevated plain covered with long grass; and to the N. is a conical hill dedicated to Mahadeva, and described as forming an irregular oval, approaching to a circle. It is 11 miles in breadth from N. to S., and 15 miles in length. It occupies the pilgrims five days to go round the lake, which from its form appears as if it had been the crater of a volcano. From this lake, according to the notions of the Hindus, flow four of their venerated rivers; but recent surveys have corrected this mistake, and it has now been satisfactorily ascertained that the only river which has its origin in this lake is the Sutlej. Moorcroft, who visited Lake Mansarowar in 1812, was of opinion that it had no considerable outlet. The water is clear and well tasted, and is supposed to be deepest in August and September, when it is replenished by the melting of the mountain snows. In the adjoining country are found wild horses, the yak of Tartary, and goats which produce shawl wool. It is supposed to be situated about 81. E. Long. and 31. N. Lat.

MANSART, François, a celebrated French architect, descended from a family originally Italian, was born at Paris in 1598. He was instructed in the principles of his art by his uncle, Germain Gautier, architect to the king, and first became known by his construction of several châteaus and hôtels. In 1632 he contributed the plan of the Eglise des Filles Sainte Marie. Not long afterwards Anne of Austria, the mother of Louis XIV., employed him to construct the Val de Grâce. After the structure had been partially erected, however, Mansart proposed to re-commence it on a new plan; but as this step met with the disapproval of the queen-mother, the completion of the edifice passed into other hands. The instability of purpose from which this slight arose became the besetting infirmity of Mansart, and afterwards prevented him from being intrusted with the buildings of the Louvre. Two of his masterpieces were the Eglise des Dames de Sainte Marie of Chaillot, and the Château de Maisons near St Germain-en-Laye. His last work was the façade of Eglise des Minimes in the Place Royale. He died at Paris in 1666. To him we owe the curb roof, which, after the name of its inventor, is still called a *mansard*.

Mansart, *Jules Hardouin*, a celebrated French architect, the son of Hardouin the painter, and of a sister of the above-mentioned François Mansart, was born at Paris in 1645. He studied architecture under his uncle, and afterwards assumed his name. Recommended to the notice of Louis XIV., he was intrusted by that monarch with the construction of many important edifices. His most notable works are the Château de Versailles and the Hôtel des Invalides. He also planned the Château de Marly, Château du Grand Trianon, the Place Vendôme, the Place des Victoires, the Château de Dampierre, and the church of Notre Dame at Versailles. As a reward for his services, Mansart received from Louis XIV. the Order of St Michael. He was also appointed chief architect and superintendent of buildings, arts, and manufactures. The large fortune which he reaped from these offices drew upon him much envy, and had he not been firmly fixed in the king's favour, it might have caused his downfall. He died suddenly in May 1708. Over his grave, in the church of St Paul at Paris, a tomb, executed by the sculptor Coysevox, was erected.

MANSFIELD, a market-town of England, county of Nottingham, pleasantly situated in Sherwood Forest, in a valley near the small River Maun or Mann, from which probably it takes its name, 14 miles N. by W. from Nottingham, and 147 from London by railway. The town is ancient, but contains also many good modern houses; and is paved and lighted with gas. In the market-place stands an elegant cross, recently erected in memory of Lord George Bentinck. The principal buildings in the town are,—the county hall, a theatre, and the parish church of St Peter, built principally in the Norman style, but repaired at different times in various styles. The other churches in the town belong to the Presbyterians, the Wesleyan and Calvinistic Methodists, and the Society of Friends. There is a grammar school, founded by Queen Elizabeth in 1567, and two charity schools, besides Sunday-schools attached to all the churches, and several benevolent institutions. The principal manufactures of Mansfield are cotton, hosiery, and lace. The trade of Mansfield, consisting chiefly of corn and malt, as well as in the building stone quarried in the neighbourhood, is much favoured by a railway connecting Mansfield with the Cromford Canal, and also by a branch of the North Midland Railway, which has its terminus here. Petty sessions are held here, and also the elections for the northern division of the county. The market-day is Thursday; and large cattle fairs are held three times a-year. Pop. (1851) 10,012.

MANSURAH, or El-Mansoorah, a town in Lower Egypt, and capital of a province of the same name, is situated on the right bank of the Damietta branch of the Nile, 34 miles S.W. of Damietta. It is one of the most considerable towns in the delta, and holds the sixth rank among the provincial towns in Egypt. The streets are narrow, and the houses are built chiefly of brick. It possesses a government cotton factory, a public school, and six mosques. There are no ancient ruins here or in the neighbourhood. Its principal manufactures are a sort of crape sail-cloth, and cotton and linen stuffs. (See Egypt.)

MANT, Richard, D.D., an eminent Irish prelate of the present century, was born at Southampton, where his father held a rectorship, on the 12th February 1776. He entered Winchester College in 1789, and Trinity College, Oxford, in 1793, where he took his bachelor's degree in 1797. He was elected a fellow of Oriel College during the following year, and he began his ecclesiastical career in 1804, as curate of Buriton in Hampshire. Mant was made vicar of Coggeshall in Essex in 1810, and of St Butolph's, Bishopsgate, London, in 1815, when he received the degree of D.D. from the university of Oxford. In 1820 he removed to Ireland, and was elevated to the bishopric of Killaloe and Kilfenora, where he remained till 1823, when he was translated to the see of Down and Connor. He died at Ballymoney in 1848, while actively pursuing the pious and philanthropic labours to which so much of his life had been devoted. Dr Mant is perhaps most generally known by his valuable *Commentary on the Bible*, which he edited in conjunction with Dr D'Oyley. Besides a vast number of sermons and tracts, and several poetical pieces, Bishop Mant is the author of *Biographical Notices of the Apostles*, &c., 1 vol. 8vo, London, 1828; *Scriptural Narratives of Christ's Life*, 1 vol. 8vo, Oxford, 1830; *History of the Church of Ireland from the Reformation to the Union of the Churches of England and Ireland in* 1801, 2 vols. 8vo, London, 1840.

MANTEGNA, Andrea, an eminent Florentine painter, was born of poor parents in the vicinity of Mantua, in 1431.

After a boyhood spent in tending flocks, he began the study of painting under Francesco Squarcione, a famous artist and teacher in Padua. So full of promise were his first attempts in the art, that his master received him into his own house, and adopted him as his son. At the age of seventeen Mantegna was intrusted in Padua with two important undertakings—the execution of an altar-piece for the church of Santa Sofia, and the painting of the chapel of San Christofano. While engaged in the latter work, he executed an altar-piece, which is now in the Brera at Milan. Mantegna sojourned for some time in Mantua, and there he secured the patronage of the Marquis Ludovico Gonzaga, for whom he painted some of his most beautiful pictures. One of these, "The Triumph of Cæsar," is considered his masterpiece, and is now seen at Hampton Court. His fame had now reached the hearing of Pope Innocent VIII., and accordingly he was summoned from Mantua to assist in the adornment of the newly-finished building of the Belvedere at Rome. Attended by the highest recommendations from his patron the marquis, he was kindly received by the pope; and after he had decorated in a most finished and elaborate style a small chapel in the palace, and had executed a picture of Our Lady with the Child, he was dismissed with much favour and honourable rewards. Mantegna was scarcely less eminent for engraving than for painting; and on his return to Mantua he executed on copper his famous picture of the Triumph. One of his last paintings was a representation of Michael the Archangel, St Andrew, St Maurice, and St Longinus, all kneeling before the Virgin with the Child, and commending to her care the Marquis Gonzaga and his wife. This picture was carried off in 1797 by the French, and is now in the Louvre at Paris. By his labours Mantegna had now earned a considerable fortune, and could thus sustain with due dignity the rank of knighthood, which had formerly been conferred upon him by his patron. He built for himself a handsome house in Mantua, where he died in 1517. Mantegna is celebrated by his contemporary Ariosto as one of the most illustrious painters of that age. "This master," says Vasari in his *Lives of the Painters*, "taught a much improved method of executing the foreshortening of figures from below upwards, which was without doubt a remarkable and difficult invention." He was esteemed for his upright conduct, and his gentle disposition, no less than for his great genius. (Lanzi, *Stor. Pittor.*)

MANTELL, Gideon Algernon, a distinguished geologist and palæontologist, was born at Lewes in Sussex in 1790. Having chosen the profession of a physician he commenced his career in his native town, where he soon established for himself an extensive practice, and began to cultivate the literature of his profession by contributions to medical journals. But it was as a man of science and as a lecturer that Mantell was destined to become known, and the accident of his position at Lewes, in the neighbourhood of an unwrought mine, by attracting his quick observation, and kindling his natural enthusiasm, directed his active energies towards that study which he afterwards enriched so greatly by discovery, and rendered so highly attractive by his happy talent for popular exposition. A richer field for observation and for the exercise of scientific tastes could scarcely have been found than that into which Dr Mantell was thrown, and few could have seized the opportunity with more zeal, or improved it with greater success. Previous to the time that he commenced his labours little was known of the nature of the Wealden formation, or of the fossils which it contained. Dr Mantell in a few years collected together from the Wealden and the chalk a museum of specimens of extinct reptiles, fishes, insects, and plants, which the trustees of the British Museum have since, at an expense of L.5000, made the property of the nation, and which alone would have been sufficient to have gained for the collector a permanent position among the promoters of geological science. The discovery and demonstration of four out of five of the strange genera of extinct Dinosaurian reptiles—viz., the *Iguanodon*, *Hylæosaurus*, *Pelorosaurus*, and *Regnosaurus*—are owing to Dr Mantell; and some of the most perfect existing remains of those singular creatures are to be found in the valuable collection of the Wealden geologist. Dr Mantell was elected a member of the Royal Society in 1825; and in recognition of his valuable labours in the comparative anatomy of fossils, and in his discovery of fossil reptiles, he was adjudged the Wollaston medal and prize by the Geological Society in 1835. During the same year he removed from Lewes to Brighton; and four years afterwards he came to London, and resided first at Clapham, and afterwards at Chester Square, still continuing his medical practice, and prosecuting with unflagging activity his favourite geological researches. In 1849 the council of the Royal Society presented Dr Mantell with the Royal Medal in acknowledgment of his discoveries in palæontology. He died at Chester Square, London, on the 10th of November 1852, aged sixty-two.

Dr Mantell did not take the position of a great generalizer or of the discoverer of new laws, yet his uncommon scientific ardour, combined with the accident of his position, and the requirements of the science, made him a great geologist. His success as a public teacher, as a popular expounder of geological facts, was unsurpassed during his time. By his numerous writings he has made a valuable addition to the geological literature of the British Islands. From 1813, when he published his first paper on the organic remains discovered in the environs of Lewes, to within a short period of his death, his literary labours were unceasing. In the *Bibliographia Zoologiæ et Geologiæ* of the Royal Society, the names of sixty-seven papers and works are given from Dr Mantell's pen. The most important of his works are,—"On the Iguanodon, a newly discovered fossil reptile, from the strata of Tilgate Forest, in Sussex," &c., *Phil. Trans.*, cxv.; "On the Discovery of the Hylæosaurus," &c., *Proc. Geol. Soc.* 1822; *Illustrations of the Geology of Sussex*, &c., London, 4to, 1827; *The Geology of the South-East of England*, 8vo, London, 1838; *The Wonders of Geology*, 2 vols. 8vo, London, 1838; *The Medals of Creation, or First Lessons in Geology*, 2 vols. 8vo, London, 1844. The last two works, besides meeting with a great degree of popularity in this country, have both been translated into German.

MANTES, a town of France, capital of a cognominal arrondissement in the department of Seine-et-Oise, is pleasantly situated on the left bank of the Seine, and connected with Limay, on the opposite bank, by two bridges and the island of Champion, which divides the river into two streams; 30 miles W.N.W. of Paris. The principal buildings are,—the church of Notre Dame, a Gothic edifice in the pointed style, with two towers and a roof of coloured tiles, which has been recently restored; the tower of St Maclou, also a Gothic structure, and the only remains of a church of the fourteenth century; the court-house; and the town-hall. It has flour-mills, tanneries, and breweries, and some trade in corn, wine, leather, &c. Mantes was taken, and reduced to ashes, by William the Conqueror, in 1087. Pop. (1851) of the town, 4298; of the arrondissement, 58,483.

MANTINEIA, a city of ancient Greece, in Arcadia, was situated on the River Ophis, near the confines of Argolis, in the centre of the valley now called the Plain of Tripolitza. It was built for the inhabitants of four or five separate villages, who had coalesced into one community, and is said to have taken its name from Mantineus, son of Lycaon. Its soldiers were engaged in the Trojan war (Hom. *Il.* ii. 607). As allies of the Spartans, the Mantineians sent their contingent to the battle of Thermopylæ. Jealous of the tyrannical policy of the Spartans, they joined the Athenian confederacy in the Peloponnesian war, but were defeated along with their allies at the first battle of Mantineia in 418 B.C. (Thucyd. v. 66–81). For some time after this they yielded a reluctant submission to the Spartans, until, on being commanded by the latter to raze their walls, they rose once more to assert their freedom. They were defeated, however, by Agesipolis, King of the Spartans, in 385 B.C., and were driven within their city. There, too, their invaders, by damming up the River Ophis on its exit from the city, and thus sapping the walls, forced them to submit. The Mantineians then retired to the humble villages in which their forefathers had dwelt, and not until the tyranny of Sparta had been broken at Leuctra (July 371 B.C.) did they return to the city, and, with the aid of the Eleians and Arcadians, rebuild the walls. (Xen. *Hell.* vi. 5.) About six years after the completion of this work, an alliance which the Mantineians had formed with their old masters the Spartans, turned against them the hostility of the Theban general Epaminondas. Accordingly, that great man encountered them in 362 B.C. at the second battle of Mantineia, and defeated them, though at the cost of his own life. In 295 B.C. a third action was fought at this city between Demetrius Poliorcetes and the Spartans (Plut. *Demetr.*); and in 242 B.C., a fourth, between the Achæans and the Spartans (Pausan. viii. 10). A league which the Mantineians formed with the Spartans in 228 B.C. once more brought them into disaster; and in 226 B.C., Aratus, leader of the Achæan confederacy, captured and occupied their city. The garrison, however, which he left was soon put to the sword, and the Mantineians continued to resist the Achæans until 222 B.C., when their city was taken and pillaged, and themselves were sold for slaves, by Antigonus Doson, King of Macedonia (Polyb. ii. 54, 58, 62). In honour of this monarch the city changed its name into Antigoneia, and it did not recover its former title until the time of Hadrian. In 207 B.C. the fifth battle of Mantineia was fought between the Lacedæmonians and Achæans. The ruins of Mantineia are seen around Paleopoli, and have been described by Leake in his *Travels in the Morea.*

MANTUA (Italian *Mantova*), a fortified town of Austrian Italy, capital of the delegation of the same name in the province of Lombardy, is situated on an island about 5 miles in circumference, standing in the middle of a lagune formed by the Mincio, and joined to the mainland by causeways perforated with arches; 21 miles S.S.W. of Verona, and 37 E. by N. of Cremona. Of the causeways the principal are the Ponte di Molini, leading to the Borgo di Fortrezza on the N., and the Ponte di San Giorgio, leading to the fortress and suburb of the same name. The latter is considered a masterpiece, and is 800 yards in length, crossing the entire lake. The city is very strongly fortified; for though the defences have not a very imposing appearance, both nature and art contribute to render it a place of very great strength. On the N. it is defended by the Borgo di Fortrezza and the Borgo di San Giorgio, the latter of which, along with the town, is surrounded by strong walls; to the S.E. it is defended by the outwork of Pradebba; and to the S. there lies the fortified island of Cerese, which is in the shape of a T, and is about twice the size of that on which the town is built. Many of the streets and squares in Mantua are broad and elegant, with well built houses; but for the most part the town is dirty and ill built. The Piazza Virgiliana is a fine square, planted with trees, and open on one side to the lake, and is much used as a public promenade. The other principal squares are,—the Piazza delle Erbe, where the market is held; the Piazza de San Pietro; and the Piazza del Argine. The principal public buildings are,—the cathedral, the work of Giulio Romano, and richly ornamented; the church of Sta. Andrea, considered one of the finest existing specimens of the Italian style, and adorned with statues of Faith and Hope by Canova; the ducal palace, an imposing building, remarkable for a fine floor of porcelain, and a room painted in fresco by Giulio Romano; the Palazzo del Te, which, though originally intended for the stables of the Gonzaga family, was increased by Giulio Romano to a large palace, and adorned by him with frescoes; and the house of Giulio Romano. There are also in Mantua numerous convents, a synagogue, an hospital, two orphan asylums, and other charitable institutions; a museum, a public library, containing 80,000 vols., as well as an arsenal, barracks, prison, &c. Mantua was formerly a place of some importance as a manufacturing town, and though now greatly decayed, still carries on some manufactures, the chief of which are,—leather, parchment, silk, linen and woollen stuffs, carriages, and boats. The climate of Mantua is subject to great extremes of heat and cold, and is rendered very unhealthy by the exhalations from the marshes with which it is surrounded. Recently, however, the Austrian government has taken measures to obviate this by draining the swamps and opening passages for the escape of the stagnant water. The city of Mantua is believed to be as old, if not older than Rome. It was not, however, distinguished until the time of Virgil. That poet was born at Andes, in the neighbourhood, which is reported to be the same as the modern Pietola. After the fall of the Roman empire, Mantua was possessed in turn by the Goths, the Longobards, and the Franks. After the conquest of North Italy by Charlemagne, Mantua became an independent republic; but afterwards became subject to the Marquises of Gonzaga, the last of whom was, in 1530, created, by the Emperor Charles V., Duke of Mantua. In the war of the succession Mantua was annexed to the Austrian dominions, of which it remained a part till the French, under Bonaparte, having gained possession of it in 1797, it became a part, first of the Cisalpine Republic, and then of the kingdom of Italy. It was finally restored to the Austrians in 1814. The delegation of Mantua is bounded on the N. by Brescia and the Lake of Garda, on the E. by Verona and Rovigo, on the S. by the duchies of Parma and Modena, and on the W. by Brescia and Cremona. Length about 36 miles, breadth about 32; area 903 square miles. The country is very fertile, and is watered by the Po, the Mincio, and the Oglio, besides many smaller streams and canals. The chief productions are,—wheat, silk, flax, hemp, fruits, wines, &c.; and horses and cattle are reared in great numbers. Pop. of the delegation (1850) 270,100, of the town (1851) 29,909, comprising 2500 Jews.

MANUEL, Jacques Antoine, a famous member of the French Chamber after the Restoration, was born at Barcelonette, in the department of Basses-Alpes, in 1775. After receiving his education at Nimes, he entered the battalions of the Requisition in 1793, and for his bravery was soon promoted to the rank of captain. On the signing of the treaty of Campo-Formio in 1797, he devoted himself to the study of law, and practised at the bar, first at Digne, and afterwards at Aix. Elected in 1815 to represent his native department in the Chamber of Deputies summoned by Napoleon, he gained his first notoriety by vehemently opposing the restoration of the Bourbons. His patriotic eloquence, though unsuccessful in attaining its object, was probably the cause of his return to the Chamber in 1818. Manuel then became an ardent defender of the benefits that France had reaped from the revolution. Borne forward by his power of logic and his heroic firmness into the front ranks of the Opposition, he soon incurred the dislike of the ruling majority, and was destined to become an object of their vengeance. During the violent debates on the Spanish war in 1823, a remark in one of his speeches was construed by his enemies into an apology for regicide. His expulsion from the Chamber was decreed, and he was forced out by a body of soldiers, but was accompanied to his house by the whole of his party. Manuel was re-elected in 1824, and died in 1827.

Manuel I., *Comnenus*, Emperor of Constantinople, son of John II., was born about 1120. The warlike disposition which he showed in an expedition against the Turks induced his father, at his death in 1143, to bequeath to him the crown in preference to his elder brother Isaac. Through the zealous policy of his faithful minister Axuch, and his own popularity among the soldiers, Manuel was enabled to secure his father's gift. Fond of military glory, he immediately involved himself in that long series of wars which continued, with few intermissions, till the end of his reign. In 1144, by means of his general Demetrius Branas, he subdued his rebellious vassal Raymond, Prince of Antioch. The next year was rendered illustrious by his expedition into Isauria, during which he routed the invading Turks, drove them to their own dominions, and forced them to accept a truce on his own terms. Manuel, however, employed a cowardly policy towards Louis VII. of France and Conrad III. of Germany, the leaders of the crusade of 1147. Granting them a passage through his dominions, he yet secretly harassed them with every kind of annoyance, and apprised the Turks of their approach. Meanwhile Roger, the first King of Sicily, had declared war against the Emperor of the East, had taken Corfu, and had devastated Greece. Manuel, however, did not make reprisals until the Sicilian fleet, in 1148, had appeared before Constantinople, and had insulted the imperial city. He then formed a league with Venice, and joining his own well-equipped fleet with that of the republic, he swept the invaders from the Archipelago and the Ionian Sea, and captured seventeen of their galleys. Disembarking a host at Corfu before the year had ended, he invested that city both by sea and land; and by leading in person the most perilous onsets, and encouraging his men by his own prodigies of strength and valour, he compelled the inhabitants to surrender after an obstinate siege. In the prosecution of the same war Manuel subdued the Servians and Hungarians, who had risen in arms at the instigation of Roger. An expedition, which he had sent against Italy under Palæologus, was also successful. Bari, Brundusium, and many other towns of Apulia and Calabria, surrendered, and Manuel now formed the project of uniting the Eastern and Western Empires, and of constituting himself sole Emperor of the Romans. By the aid of money he induced Pope Alexander III., and the free cities of Lombardy, to favour this design. But the pontiff soon afterwards changed his opinions; the free cities followed his example, and the republic of Venice, offended at some injustice offered to her merchants, also joined the foes of the Greek Empire. The death of Palæologus, his lieutenant, and the accession of William the Bad to the throne of Sicily, soon completed the sum of Manuel's misfortunes. His forces soon afterwards were defeated by land and sea, and he was induced in 1155 to conclude an honourable peace with William, King of Sicily.

The next important war of Manuel's reign was waged against Geisa, King of Hungary. That prince, eager to recover the military reputation he had lost in his former battles with the Emperor of the East, crossed the Danube, and met the Greek forces, under Andronicus Contostephanus, near Zeugminum, where, after a stubborn and sanguinary contest, the Hungarian army was almost annihilated, and Geisa compelled to sue for immediate peace. Not so successful was the expedition which Manuel led in person against the Turks in 1176. He lost his army among the mountains of Pisidia, and was compelled by the Sultan Az-ed-diu to sign a disadvantageous peace. This defeat, although partially retrieved by a more successful expedition in 1177, preyed upon the spirit of Manuel until he was cut off by a slow fever in 1181. The bravest warrior of his time, Manuel was yet destitute of the prudence and the stability of purpose proper alike to a great general and an able ruler. No sooner had he brought a war to a close, than he dismissed all thought of military enterprise, and in the long-continued indulgence of every sensual pleasure entirely forgot his former ambition. The exorbitant war taxes, wrung from the reluctant grasp of his subjects, were often expended for some unworthy purpose, while his soldiers remained unpaid. Alexis II., his only son, succeeded him.

Manuel II., *Palæologus*, Emperor of Constantinople, succeeded his father John VI. in 1391, died in 1425, at the age of 77, and was succeeded by his son John VII. (See Constantinopolitan History.)

MANUFACTURES.

Definition. Manufactures (Latin, *manus*, a hand, and *facio*, I make), in political economy, a term employed to designate the changes or modifications made by art and industry in the form or substance of material articles, in the view of rendering them capable of satisfying some want or desire of man.

With the exception of fishing, hunting, mining, and such branches of industry as have for their object to obtain material products in the state in which they are fashioned by nature, all other branches may legitimately be comprised under the term *Manufactures*. Most commonly, indeed, we include in them only those branches in which the raw material or substance to be modified or worked upon is formed or converted into the desired articles by art and industry, without the intervention of the soil or of the vegetative powers of nature. But though this limitation of the term manufactures be in many respects convenient, it must not be supposed that by adopting it, we mean to insinuate that there is any real or substantial difference between the various divisions of industry. Agriculture is merely a peculiar variety of manufacture, in which the husbandman so prepares the ground and disposes of the seed, that, with the aid of the soil, and of the sun and showers, he may obtain a plentiful harvest. Without the assistance given by nature, his efforts would not be of the smallest avail. But her bounty is not confined to this or that department. It extends to, and is equally great in them all. Without the pressure of the atmosphere, the elasticity of steam, the influence of heat, and the endless variety of natural powers by which he is constantly assisted, the manufacturer would be powerless, and could not even make or mend a pen, or accomplish the most trivial task. His art consists in so applying his own labour and the natural powers at his command, that they may bring about the required changes or modifications in the articles subjected to their action in the best and cheapest manner. At bottom all the branches of operative industry rest on the same foundation. How much soever one undertaking may differ from another, the co-operation of genius and industry, of man and of natural agents, is necessary in them all. And hence, also, it follows, that they are all susceptible of indefinite improvement according as the progress of scientific discovery gives man a greater mastery over these agents, and enables him to employ them and his own energies with increased effect.

Elements which enter into the value of manufactured articles.

The value of manufactured articles may always be resolved into the value of the raw material or matter[1] on which the skill and labour of the artisan is exerted, and the value of that labour. These may, and, in fact, do vary in almost every degree as compared with each other. In some articles they approach near to equality; in others, as in most descriptions of gold and silver wares, the value of the raw material predominates very largely; and in others the value of the workmanship is by far the greatest. The value of the main-spring of a watch, or of a steel pen, is some hundred times that of the iron of which it is made; and the value of statuary, pictures, and other products of the fine arts, is almost wholly owing to the genius and labour of the artist.

In nothing, perhaps, is the transforming power of manufacturing industry—its ability to give to matter entirely new forms and new qualities—more strikingly evinced than in the production of glass and paper. It is impossible to exaggerate either the utility or the beauty of these fabrics. To the former we are mainly indebted for the comfort of our houses, and for that range and intensity of sight which enables us to survey regions at an almost inconceivable distance, and to detect and appreciate the minutest objects; while to the latter we owe the means by which our correspondence is carried on, our books, and, in fact, the greater part of our knowledge. And these inestimable *commoda vitæ* are formed out of such despised materials as sand, soda, and rags. In this case, and in that of many other articles, the metamorphosis is so very complete, that none who saw only the products, and knew nothing of their manufacture, would ever conjecture whence they had been derived. Though not productive of matter, industry is often productive of everything which makes it either desirable or valuable.

In saying that the value of manufactured goods is made up of the value of the raw material and the workmanship, it may perhaps be objected that nothing is set down to the account of natural agents. But though their co-operation be of the utmost importance, and generally, indeed, quite indispensable, yet as they are spontaneous gifts of nature, which may be appropriated by every body, and cost nothing, they have no exchangeable value, and cannot communicate a quality of which they are destitute to any thing else. In estimating, for example, the cost of importing a cargo of tea from China, or the value of the work performed by a locomotive engine, the buoyancy of the water, the action of the wind, the polarity of the magnet, and the expansive force of heated aqueous vapour, though contributing in the most essential manner to the results which, in fact, could not be accomplished without their powerful aid, are as completely left out of view as if they did not even exist. This principle is of fundamental importance, and holds universally. Whatever is useful or desirable in art and industry is a consequence or result of the labour or action of man, of capital, or of natural agents, or of two or all three combined. But in so far as the latter are concerned, their services are completely gratuitous; so that the cost or value of the result is always measured, without any reference to them, by the amount of labour or capital (the product of labour) or both, necessarily expended in bringing it about.

In this article manufactures are considered in their ordinary and limited sense, as comprising the processes whereby the required changes or modifications are produced, independently of vegetation, in existing substances or materials. The latter usually give their names to the peculiar departments wherein the processes to which they are severally subjected are carried on. Thus the designations of cotton, silk, and woollen manufactures, mean the working up of cotton-wool, raw silk, and sheep's wool into useful or desirable articles. Ship-building is the conversion of iron and wood, or of either, into ships. The linen manufacture is the conversion of flax into cloth; and so on. The knowledge of the modes in which particular businesses may be most profitably conducted, forms the peculiar science, craft, or mystery of those engaged in them.

It would far exceed our limits to enter into any details in regard to the management of different businesses; but there are certain circumstances or conditions which are necessary, and others which eminently contribute to the success of all varieties of manufacturing industry, and these we shall endeavour shortly to state. We shall also take leave to notice some of the peculiar drawbacks by which the great extension of manufactures is said to be accompanied, with the means by which they may be most effectually obviated, the economy and locality of factories, &c.

I. CIRCUMSTANCES FAVOURABLE TO THE PROGRESS OF MANUFACTURING INDUSTRY.

Circumstances conducing to the progress of manufactures.

These are partly of a moral and political, and partly of a physical description. Of the former class the most important seem to be the security and free disposal of persons and property; the absence of monopolies, and the non-interference of government in industrious undertakings; the freedom of commerce; the diffusion of knowledge; the cordial reception of foreigners; and the emulation and energy inspired by inequality of fortune and the gradual increase of taxation. Among the more prominent of the physical circumstances conducive to their progress are,—supplies of the raw material used in manufactures, with the command of power; that is, of coal, waterfalls, &c. A good deal also of the progress of manufactures seems to depend on the advantageous situation of a country for commerce, and on the nature of its climate. We shall briefly notice some of the more prominent of these circumstances.

Moral circumstances contributing to the progress of manufactures.

a. Moral circumstances contributing to the Progress of Manufactures.—It is unnecessary to take up the reader's time by enlarging on the necessity of security, and of the free disposal of property, to success in manufacturing industry, and, indeed, in all laborious undertakings. Without security there can be neither industry nor invention. No man will engage in any undertaking, or exert either his bodily or mental powers, unless he be well convinced that he will be allowed to reap whatever advantage may accrue from the exertion of his labour, skill, or genius. Any doubt as to this is sure to paralyze his efforts. And if, owing to the weakness or ignorance of government, the prevalence of a revolutionary spirit, or other cause, the security of property were materially impaired, all sorts of industrious undertakings that did not promise an immediate return would be forthwith abandoned, and every person possessed of property would hasten to convey it out of the country. The want of security is the greatest of public calamities. Without it we can have nothing but the most abject poverty and barbarism. And supposing other things to be equal, the wealth and civilization of nations will be pretty nearly proportioned to the degree of security they respectively enjoy. Though every other circumstance conducive to the advancement of industry should exist in a country, they cannot, without security, be of any

Security.

---

[1] It is unnecessary for the purposes of this article to analyze the value of the raw material. In point of fact, however, it is wholly made up of the value of the labour required for its appropriation and conveyance to the place where it is to be modified or manufactured. The matter of commodities costs nothing. What is commonly called raw material has frequently a great deal of labour expended on its manufacture, as in the case of pig or bar iron, cotton wool, raw silk, flax, &c.

matcrial service. It compensates for many deficiencies; whereas nothing can make up for its wants. It is a *sine quâ non.*

By the security indispensable to success in manufactures is not, however, meant that degree of security which exists in most countries that have made any progress in civilization, viz., the free enjoyment of the fruits of one's labour or ingenuity. Much more than this is required to make industrious undertakings be prosecuted on a grand scale with zeal and perseverance. Administration must be established on such a basis that the freedom and independence of those by whom manufactures are carried on may be as effectually secured as their property. The latter must be guaranteed against all arbitrary proceedings, whether on the part of government or of private parties. The standard of money must be preserved inviolate; public burdens fairly and equally imposed; justice speedily, cheaply, and honestly administered; and testators have full liberty to dispose of their property as they may think fit. Wherever any of these things are wanting, there can be no complete security; and, therefore, none of that unhesitating confidence which makes capitalists invest large sums, of which posterity is to reap the principal or entire advantage; and which also gives its fullest extension to private and public enterprise and credit. That accumulation of capital which has taken place in England during the last hundred years, and which, besides enabling us to defray with little difficulty the cost of so many protracted and destructive wars, has covered the land with cities and all sorts of improvements, and the ocean with ships, would either not have taken place at all, or but in a very subordinate degree, had there been any serious doubt about its present or future security, or about the ability of the owner to employ it or bequeath it at pleasure. The various circumstances that will be immediately mentioned give us peculiar means and advantages for the production of wealth. But the consciousness of security is required to make these circumstances be turned to the best account, and the produce of industry largely saved and accumulated. And the more intense this consciousness becomes, the greater, *cæteris paribus*, will be the progress of the society in arts and industry.

Freedom of industry.

The absence of monopolies, and the freedom to engage in industrious undertakings, conduce in no ordinary degree to the advancement of the arts. Every man is always exerting himself to find out how he may best extend his command over necessaries and conveniences; and sound policy requires that so long as he does not interfere with the rights and privileges of others, he should be allowed to pursue his own interest in his own way. Though human reason is limited and fallible, and we are often swayed by prejudices, and deceived by appearances, still it is sufficiently certain that the desire to promote our own purposes contributes more than anything else to render us clear-sighted and sagacious. "*Nul sentiment dans l'homme*," says M. Say, "*ne tient son intelligence éveillée autant que l'intérêt personnel. Il donne de l'esprit aux plus simples.*" The principle that individuals are, speaking generally, the best judges of what is most beneficial for themselves, is now universally admitted to be the only one that can be safely relied on. No writer of authority has latterly ventured to maintain the doctrine, once so popular, that governments may advantageously interfere to regulate the pursuits of their subjects. It is their duty to preserve order; to prevent one from injuring another; to maintain, in short, the equal rights and privileges of all. But it is not possible for them to go one step further without receding from the principle of non-interference, and laying themselves open to the charge of acting partially by some and unjustly by others.

The most comprehensive experience confirms the truth of these remarks. The natural order of things has been less interfered with in Great Britain than in most other countries. Since the passing of the act of James I., in 1624, for the abolition of monopolies, full scope has been given to the competition of the home producers; and though the various resources of talent and genius have neither been so fully nor so early developed as they would have been had there been no restrictions on our intercourse with foreigners, they have been developed in a degree unknown to most other countries. France, previously to the Revolution, was divided into provinces, having each peculiar privileges and separate codes of revenue laws, and this also was the case with Germany, Spain, and Italy, so that they were not only deprived of the freedom of foreign, but even of internal, commerce. The inhabitants of each province being in great measure isolated from the rest, there was comparatively little competition; and instead of invention and active exertion, there was nothing but routine and indifference. Holland and the United States have been the only countries that have enjoyed the same degree of internal freedom as Great Britain: And the former, notwithstanding the unfavourable physical circumstances under which she is placed, has long been, and still is, the richest country of Europe; while the latter, whose condition is in other respects more favourable, is advancing with giant steps in the career of improvement.

But the freedom of the home trade, or the stimulus given to invention by the competition of the different parties within the same country, how advantageous soever, is always very inferior to the stimulus given by an unrestricted foreign trade. A nation which admits, either freely or under moderate duties, the various productions of others, adopts that line of policy which is sure to bring her energies into the fullest activity. She profits by whatever inventions and discoveries may be made in countries the most remote, as well as among her nearest neighbours; at the same time that her manufacturers have not only to contend with each other, but with those of every other people. In a system of this sort, no branch or department of industry can be artificially bolstered up. Each must depend upon its own resources. And if, during a restricted trade, a business were introduced into a country which had no peculiar aptitude for carrying it on, it would most likely be extinguished when trade was made free. But this extinction, instead of being a loss to such country, is a gain. The capital and labour which were engaged in an unprofitable business, will henceforth be diverted to those pursuits which the inhabitants can carry on with more advantage; and their wealth, and that of the community of nations, will be increased by the better distribution of their labour.

Division of employments.

It would be useless to enter, even if our limits permitted, into any lengthened details in regard to the advantages resulting to society from the division of labour; that is, from the execution of certain tasks or duties being committed to particular persons, possessing the age, strength, skill, and other qualifications required for their proper performance. These have been set in a clear light by Adam Smith and others, and are familiar to everybody. But it is not, perhaps, so generally known, that the division of labour is in a great degree dependent on the extent of the market, and that it becomes more perfect and complete according as the latter is more and more extended. There are many employments that cannot be carried on in thinly peopled countries; and of those that are, or may be, carried on in them or in others, there is hardly one which may not be improved and perfected by increasing the demand for the peculiar services or articles which it furnishes. To be satisfied of the truth of this statement we have only to look around us. Take the case of the cotton, the woollen, or the iron manufacture. These great departments of industry could not have attained to such vast magnitude, or been furnished with the complex machinery and the skilfully distributed labour employed in them, had the demand for their products been confined to a single province, or even to a single kingdom. Nothing less extensive than the market of the world would afford a field wide enough to keep them in constant employment. And hence it is, that while the freedom of trade stimulates the industry and ingenuity of the home producers, by bringing them into competition with myriads of foreigners, it affords an illimitable market for those products in which they have a superiority; and enables them continually to perfect every process, and to carry the employment of machinery and the division of labour to the greatest extent.

Extension of industry since 1842.

It is needless, however, to insist on considerations the justice of which is now all but universally admitted. But it was necessary, nevertheless, thus briefly to allude to them, inasmuch as they satisfactorily account for the greater part of the late extraordinary increase of our trade; that is, of its increase from the time that the commercial reforms of Sir Robert Peel came into full operation. Since 1842 the declared annual values of the exports of British produce have been as follows, viz.:—

Years.	Annual value.	Years.	Annual value.
1842	L.47,381,023	1850	L.71,359,184
1843	52,279,709	1851	74,488,722
1844	58,584,292	1852	78,076,854
1845	60,111,082	1853	98,933,781
1846	57,786,876	1854	97,184,726
1847	58,842,377	1855	95,688,085
1848	52,849,445	1856	115,890,857
1849	63,596,025		

The raw products included in the exports consist principally, as usually estimated, of unwrought iron, copper, tin, and lead; with coal, sheep's wool, butter, fish, salt, and a few other articles; their entire value not exceeding a seventh or an eighth part of the value of the exports. But we are by no means satisfied that iron and other metals should be reckoned in the list of raw products. On the contrary, we are clear that that designation should be restricted to the ores of the metals, and that it should not be applied to the metals after they have been extracted by an elaborate process from the ores. And supposing this classification were adopted, and the unwrought metals excluded from the list of raw products, the latter would not exceed a fifteenth or a sixteenth part of the entire amount of the exports.

The unprecedented increase in the value of the exports, exhibited in the above table, is in great measure the result of the policy of Sir Robert Peel, who, by repealing and greatly reducing the duties on most descriptions of foreign produce, occasioned a vast increase of importation. But he knew well that a great importation would occasion a great exportation; that the latter would increase in the same ratio as the former; and that by a free intercourse with others our manufacturing and industrial powers would be sharpened and improved to the utmost. And such has proved to be the case in a far greater degree than he, or any one, however sanguine or far-sighted, could have anticipated. The new system has brought all the faculties of the mind, and powers of the body, into full activity. And while the improvements of a century have been crowded into the short space of ten or a dozen years, we continue with unimpaired energy to make new inventions and discoveries.

But though the extraordinary increase of our trade since 1842 has been mainly (we should err if we supposed that it was wholly), owing to the greater freedom it has enjoyed during that period. Part of it is to be ascribed to the discovery of the gold-fields of California and Australia. Their astonishing productiveness, the encouragement they have given to emigration, and the rapid growth of a population which has had an almost unbounded command of the precious metals, at the same time that it has been destitute of most articles of accommodation, have led to an extraordinary demand for foreign produce, and especially for our manufactures. But it must not be forgotten that it was our comparatively free commercial policy that enabled us to avail ourselves to so great an extent of these advantages; and the presumption is, that but for it, we should have profited as little by them as the countries around us.

Diffusion of information.

The ability to read, and the diffusion of instruction among all ranks and orders of the people, by the circulation of books and journals, the establishment of mechanics' institutes, &c., have had a material influence over the advancement of arts and industry. These circumstances have had the double advantage of multiplying the means and chances of improvement, and of preventing any invention or discovery, when made, from being lost or engrossed by a few. An uninstructed people, though possessed of the greatest capacities for the production and accumulation of wealth, being unable to turn them to good account, are usually poor and destitute; whereas an intelligent people, though placed in a comparatively unfavourable situation, never fail to become rich and prosperous. That "knowledge is power," is true in a physical as well as in a moral sense. The more familiar our acquaintance with, and the more complete our command over, natural agents, the greater, of course, will be our ability to make them subservient to our purposes, and to employ their untiring and boundless energies in the performance of that labour that must otherwise be wholly performed by man. The proud pre-eminence of civilized man over his less advanced brethren, mainly consists in the extensive employment of these agents. Like other things, production is proportioned to the strength of the means by which it is effected. The accommodations of a people in a low or backward state of civilization, who have nothing but their fingers and a few rude tools or simple instruments at their disposal, are necessarily limited in the extreme; whereas a people highly advanced in the arts press all the powers of nature into their service, and have an all but unlimited command of the various articles required for their subsistence and wellbeing.

Immigration of foreigners.

For a lengthened period the reception given to foreigners in England was anything but cordial. In most countries, indeed, not advanced in civilization, strangers are uniformly the objects of popular dislike; and this feeling seems to have prevailed quite as much in England as anywhere else. But notwithstanding the various legal disabilities laid on foreigners, and the ill treatment they often experienced, their settlement here has been productive of the most advantageous results. The Flemings, invited over and protected by Edward III., gave the first great impulse to the woollen manufacture; and the immigrations from the Low Countries during the persecutions of the Duke of Alva, and from France subsequently to the revocation of the Edict of Nantes, materially forwarded our trade and manufactures. During last century the prejudice against aliens lost much of its force; and most part of the disabilities under which they formerly laboured have been removed. But in all that respects the treatment of foreigners our policy has been less liberal and enlightened than that of the Dutch. In Holland they have always been received with open arms; and a short residence in the country, and a small payment to the state, entitled them to all the privileges enjoyed by natives. The highest authorities agree that this was one of the main causes of the extraordinary progress made by the republic in commerce and wealth. "It has always been our constant policy to make Holland a perpetual, safe, and secure asylum for all persecuted and oppressed strangers: no alliance, no treaty, no regard for, nor any solicitation of, any potentate whatever, has at any time been able to weaken or destroy, or make the state recede from protecting those who have fled to it for their own security and self-preservation. Throughout the whole course of all the persecutions and oppressions that have occurred in other countries, the steady adherence of the republic to this fundamental law has been the cause that many people have not only fled hither for refuge, with their whole stock in ready cash, and their most valuable effects, but have also settled and established many trades, fabrics, manufactures, arts, and sciences, in this country; notwithstanding the first materials for the said fabrics and manufactures were almost wholly wanting in it, and not to be procured but at a great expense from foreign parts."[1]

Inequality of fortune.

The great inequality of fortune that has always prevailed in this country has had a material influence in exciting a spirit of invention and industry among the less opulent classes. It is not always because a man is absolutely poor that he is industrious and economical. He may have already amassed considerable wealth; but he continues with unabated energy to avail himself of every means by which he may hope to add to his fortune, that he may place himself on a level with the great landed proprietors, and those who give the tone to society in all that regards expense. No successful manufacturer or merchant ever considers that he has enough till he is able to live in something like the same style as the most opulent noblemen. Those, again, who are immediately below the highest become a standard to which the class next to them endeavour to elevate themselves; the impulse extending in this way from one rank to another, till it reaches to the very lowest classes, individuals belonging to which are always raising themselves by industry, address, and good fortune to the highest places in society. Had there been less inequality of fortune amongst us, there would have been less emulation, and industry would not have been so earnestly prosecuted. It is true, that the desire to emulate the great and the affluent, by embarking in a lavish course of expenditure, is often prematurely indulged in and carried to a culpable excess. But the evils thence arising make but a trifling deduction from the beneficial influence of that powerful stimulus which it gives to the inventive faculties, and to that desire to improve our condition, and to mount in the scale of society, which is the source of all that is great and elevated. Hence we should strongly disapprove of any system which, like the law of equal inheritance established in France, had any tendency artificially to equalize fortunes. To the absence of any such law, and the prevalence of customs of a totally different character, we may safely attribute a considerable portion of our superior wealth and industry.

Increase of taxation.

We are also disposed to believe, how paradoxical soever such a notion may appear, that the taxation to which we have been subjected has, hitherto at least, been favourable to the progress of the country. It is not enough that a man has the means of rising in the world within his command; he must be so placed that, unless he avail himself of them, and put forth his energies, he will be cast down to a lower station. And this is what our taxation has effected: to the desire of rising in the world, implanted in the breast of every man, it superadded the fear of being thrown down to a lower place in society; and the two principles combined produced results that could not have been produced by either separately. Had taxation been carried beyond due bounds it would not have had this effect. But though considerable, its increase was not such as to make the contributors despair of being able to meet the sacrifices it imposed by increased skill and economy. And as the efforts they made in this view were far more than sufficient for their object, they occasioned a large addition to the public wealth that might not otherwise have existed.

Physical circumstances contributing to the progress of manufactures.

b. Physical circumstances contributing to the progress of Manufactures.—Supplies of the raw material may be classed among the more prominent of this description of circumstances; and those who reflect on the nature, value, and importance of our manufactures of wool; of the useful metals, such as iron, tin, lead, copper, &c.; of leather and flax, spirits and beer, and so on; will readily admit that our success in them has been materially facilitated by our possessing abundant supplies of the raw material. It is of less consequence, when the material of a manufacture possesses considerable value in small bulk, whether it be furnished from native resources, or be imported from abroad; though even in that case the advantage of having an internal supply, of which we cannot be deprived by the jealousy or hostility of others, is far from immaterial. But no nation can make any considerable progress in the manufacture of bulky and heavy articles, the conveyance of which to a distance necessarily occasions a large expense, unless she have supplies of the raw material within herself. Had we been destitute of iron ore, lead, and tin, we could never have distinguished ourselves by the magnitude and value of our manufactures of these articles. And any one who reflects on the advantages, resulting to every branch of industry from being able to procure abundant supplies of iron at the cheapest rate, will be convinced that it is no easy matter to exaggerate the obligations we are under to our exhaustless stores of that mineral.

Locke on supplies of iron.

There is a passage in Locke so applicable to this subject that it deserves to be quoted:—"Of what consequence the discovery of one natural body and its properties may be to human life, the whole great continent of America is a convincing instance; whose ignorance in useful arts, and want of the greatest part of the conveniences of life, in a country that abounded with all sorts of natural plenty, I think may be attributed to their ignorance of what was to be found in a very ordinary despicable stone—I mean the mineral of iron. And whatever we think of our parts or improvements in this part of the world, where knowledge and plenty seem to vie with each other, yet to any one that will seriously reflect on it, I suppose it will appear past doubt, that were the use of iron lost among us, we should in a few ages be unavoidably reduced to the wants and ignorance of the ancient savage Americans, whose natural endowments and provisions come no way short of those of the most flourishing and polite nations. So that he who first made known the use of that contemptible mineral, may be truly styled the father of arts and author of plenty."[2]

Supplies of coal.

But of all the physical circumstances that have contributed to our advancement in manufactures and arts, none have had so much influence as our possession of the most valuable coal mines. They have conferred advantages on us not enjoyed in an equal degree by any other people. Our extraordinary success in the manufacture of iron, copper, &c., is not owing so much to our possessing the ores of these metals, as to our possessing the coal, by the aid of which the ores have been smelted and refined. But the paramount importance of coal as a manufacturing agent has been principally manifested since the invention of the steam-engine. Without a cheap and abundant supply of fuel, the engine, as now constructed, would be of comparatively little use. It is, as it were, the hands; but coal is the muscles by which they are set in motion, and without which their strength and dexterity could not be called into action, and would be of no use. Our coal mines may be regarded as vast magazines of *hoarded* or *warehoused power*; and, unless some such radical change be made on the steam-engine as should very decidedly lessen the quantity of fuel required to keep it in motion, or some equally serviceable machine, but moved by different means, be introduced, it is not at all likely that any nation should come into successful competition with us in those departments in which steam-engines, or machinery moved by steam, may be profitably employed.

---

Advantageous situation.

The advantageous situation of Britain for commerce, and the nature of the climate, have also powerfully contributed to the perfection of industry. Had we occupied a central internal situation like that of Switzerland, our facilities for dealing with others being so much the less, our progress would have been comparatively slow; and instead of being highly improved, our manufactures might have been still in their infancy. But being surrounded on all sides by the sea, or great highway of nations, we have been able to maintain an intercourse with the most remote as well as with the nearest countries, to supply them on the easiest terms with our manufactures, and to profit by the peculiar products and capacities of production possessed by each. With such advantages on our side, it would have been singular had we not shot ahead of most of our competitors in the race of improvement.

Climate.

Our climate is peculiarly favourable to exertion and enterprise. It admits of most sorts of labour being vigorously prosecuted, even when the thermometer is highest; while its severity, without being too great, makes comfortable clothing and lodging indispensable; and, consequently, gives rise to numerous wants that, being either unknown or little sensible in more genial climates, require proportionally greater efforts for their supply. Its inequality, too, by requiring incessant care and attention on the part of the husbandmen, makes them vigilant and active as well as laborious; and the qualities that are thus naturally impressed on this great class are, through their example, universally diffused.

But despite what has been stated above, we are disposed to believe, how unphilosophical soever it may seem, that a good deal in the history of industry must be ascribed to chance, or to some lucky accident. Had Hargreaves, Arkwright, Watt, and Wedgwood not existed, or been born abroad, it is impossible to say how much it might have affected the state of industry here and elsewhere; but there appear to be sufficient grounds for thinking that it would have been at this moment materially different from what it actually is. A good deal, too, depends on priority. A country, town, or district, that has already established and made a considerable progress in manufactures, acquires, in consequence, an advantage that may enable it successfully to contend with competitors placed under what are naturally more favourable circumstances. But these are matters that will be noticed afterwards.

It seems to be the peculiar good fortune of England that, as respects all the great branches of manufacture, she has at once the advantages of priority and of acquired skill and dexterity on her side, as well as the natural advantages already noticed of abundant supplies of the raw material, of inexhaustible beds of coal, and of situation. Cotton is not an exception; for, though the raw material be the product of other countries, the freight upon it is not very considerable, and is but a trifling deduction from the other circumstances that seem to insure our superiority in its manufacture.

Machinery.

It may be said, perhaps, that in thus briefly enumerating what seem to be principal causes of the superiority to which Great Britain has attained in manufactures, we have omitted to notice that which many reckon the most important of them all, viz., the comparative excellence of our machinery. But the production of machinery is itself a branch of manufacture, success in which depends on the same circumstances that determine success in other branches. The manufacture of machinery is, however, in so far peculiar, that superiority in it conduces, more directly than superiority in anything else, to the improvement of all descriptions of manufacture. Machines are the tools or instruments by which most industrious undertakings are either partly or wholly carried on. And hence it is, that while a marked superiority in various branches of industry may exist, where machinery is defective, simultaneously with great inferiority in others, this is hardly possible where it is highly improved. Eminence in machine-making is almost sure to lead to eminence in every other department, and is the best means for securing their advancement.

Our superiority in the manufacture of machinery depends principally on the greater intelligence of our work-people, and our unlimited supplies of coal and iron. The latter is now either exclusively or largely used in the construction of ships and houses, and of a vast variety of instruments and articles that were formerly either wholly or in great part made of wood; and their efficiency and cheapness have been in consequence very greatly increased. The steam-engine, which is made entirely of iron, performs for us the work of many hundreds of thousands of men, and of many hundreds of thousands of horses; and while it performs most part of this work incomparably better than it could have been performed by men and horses, it saves a vast amount of toil and suffering. The slavish occupation of thrashing out corn is now wholly performed by thrashing-mills, which are mostly moved by steam; and at the same time that the employment of locomotive engines on railways has added greatly to the security of travelling, and make it be performed with a speed inferior only to that of lightning, it has terminated that over-exertion which the noblest of the lower animals were formerly compelled to make in the running of stage-coaches. It is impossible, in truth, to over-rate the advantages man owes to machinery; and the idea that it may be too much perfected or extended, is the most futile and absurd that can be imagined.

Besides the great discoveries—such as the introduction of the spinning-frame, the steam-engine, and the power-loom, which suddenly change the whole aspect and economy of industry, a variety of minor improvements are always being introduced, which, though separately they may be little attended to by careless observers, have in the aggregate a powerful influence. The economizing of power, the production of the same or better articles at less expense, the substitution of cheaper or more efficient, for dearer or less efficient labour, and so forth, are objects ever present to the mind of the intelligent manufacturer; and the advance made in them in the course of a few years is usually very great.

The late improvements in the steam-engine may be referred to as affording a striking illustration of what has now been stated. For a lengthened period after it came from the hands of Watt it remained nearly stationary. But during the last twenty, and more especially during the last ten years, many important innovations have been made, by driving the engines with greater speed, enlarging the capacity and improving the form of the boilers, and so on; the result being, that from the same weight of steam machinery we now obtain, at an average, at least 50 per cent. more work than formerly; and that, in many cases, the identical engines that yielded fifty horse power, are now yielding upwards of 100 horse power, with little or no increase of expense.[1]

Exportation of machinery.

The manufacture of machinery for exportation is now become a large and rapidly increasing business. This is evident from the following account of the declared value of the exports of machinery from 1842 down to 1856, viz.:—

---

[1] Letter of Mr Nasmyth of Patricroft, near Manchester, an eminent engineer, in one of Mr Horner's Reports for 1852.

Years.	Value.	Years.	Value.
1842	L.554,653	1850	L.1,042,167
1843	713,474	1851	1,168,611
1844	776.255	1852	1,251,360
1845	904,961	1853	1,985,536
1846	1,117,470	1854	1,930,860
1847	1,263,016	1855	2,211,215
1848	817,656	1856	2,717,572
1849	700,631		

It has, however, been frequently contended, and by parties not otherwise opposed to the freedom of trade, that in permitting the exportation of machinery we act unwisely; and in fact furnish our rivals in other countries with the principal instruments of our manufacturing superiority. But though specious, this statement is not entitled to much weight. It is not in our power, even if we attempted it, to enforce a monopoly of our improved machinery. The plans and patents according to which it is made, are published and sold to all who choose to buy them, whether natives or foreigners. And not only this, but English engineers, and the artizans by whom machines are made, are met with in every civilized country. All, therefore, that we should effect by prohibiting the exportation of the latter, would be the suppression of a large and lucrative branch of business; while, by forcing the foreigners to construct that machinery and mill-work for themselves, which they now buy from us, we should stimulate their invention, and endanger our ascendancy in a department which is not likely to be disturbed so long as we abide by our present policy.

II.—DISADVANTAGES SUPPOSED TO ATTEND MANUFACTURING EMINENCE.

Supposed disadvantages of manufactures.

The above seem to be the principal circumstances which have contributed to the rapid growth of manufactures in Great Britain. This growth has not, however, been always regarded as advantageous. On the contrary, many eminent authorities have doubted whether the great extension of the manufacturing system be not accompanied with so many drawbacks as go far to countervail its beneficial influence.

Introduction of machinery.

It is, for example, alleged, that of the improvements which contribute so greatly to the extension of manufactures, some are occasionally productive of injury to the work-people. But it may be easily shown that this allegation is not worthy of much attention. The inconveniences which sometimes attend the introduction of improved machines and processes are merely temporary. If by an improvement in the manufacture of hats, or any other cause, the cost of their production were reduced a half, it is probable that the wages of the hands now engaged in the hat trade would be reduced, and that some of them would be dismissed. A little consideration will, however, make it evident that these disadvantageous results cannot fail of being very soon obviated; for, as those who formerly paid 10s. or 20s. for hats, will now only pay 5s. or 10s., they will have so much more to expend on other things. The demand for produce of one sort or other will not, therefore, be diminished; and the result will be, first, that hats being cheaper, more of them will be demanded; and, second, that a part of the money formerly laid out on them will henceforth be laid out on other things, the manufacture of which will give full employment to the artizans thrown out of the hat trade. Hence, in the end, it will be found, that while everybody is supplied with hats at half their former cost, not one individual will be deprived of employment, or have his wages reduced. And such is the invariable result of all improvements in the arts, and of the opening of markets whence produce may be imported at a reduced price.

But short as this statement is, it was hardly necessary to show that improvements in machinery cannot really injure the labourer. To be satisfied of this, we have only to cast a rapid glance at the progress of the greatest of our manufactures. So late as 1760, not more, perhaps, than 3000 or 4000 persons were dependent in Great Britain on the cotton manufacture, which was so trifling as scarcely to attract any notice. But such and so vast has been the change in the interval, that the cotton trade is now, next to agriculture, the most important branch of industry carried on in the kingdom, furnishing the means of subsistence to from 1,250,000 to 1,500,000 persons. And to what but the improvement and extension of machinery are we indebted for this result, which has no parallel in the history of industry? The inventions and discoveries of Arkwright, Watt, Compton, Cartwright, and others, have created this all but boundless field for the employment of capital and work-people. The more efficient the machinery introduced the greater has been the demand for fresh supplies of labour; and such will necessarily be the result in all similar cases in all time to come.

In the course of its marvellous progress, some departments of the manufacture have come to be carried on by wholly different agents. Hand-spinning, whether by the common wheel or the jenny, has entirely disappeared; and hand-loom weaving is fast approaching its termination. And though its long agony has entailed many privations on a large number of persons, it should be borne in mind that the condition of the weavers, owing probably to the facility with which the business was learned, has never been prosperous. Luckily, they are now being rapidly absorbed into other businesses; and there cannot be a doubt that the final extinction of the class will be of especial advantage to the labourers.

The following table exhibits an account of the number of power-looms in 1836, 1850, and 1856:—

Fabric.	1836.	1850.	1856.
Cotton	108,751	249,627	298,847
Woollen	2,150	8,439	14,453
Worsted	2,969	32,617	38,956
Silk	1,714	6,092	9,260
Flax	209	3,670	7,689
Total	115,793	301,445	369,205

The rapid increase in the number of power-looms employed in the linen trade has been in great measure owing to their extended use in Ireland. This has been accelerated by the rise in the price of labour consequent on the potato rot and the emigration; but it would have taken place, though not, perhaps, so soon, independently of these circumstances. Notwithstanding the cheapness of labour in Ireland, the flax manufacture made no real progress in it till yarn was spun in factories; and the substitution of power-looms for hand-looms originates in the same cause,—in the wish to profit by the cheaper and more efficient service rendered by improved machinery. (See POST.)

Except in anomalous cases, like that of hand-loom weavers, the difficulties to which work-people are subjected in moving from a department to which they have been accustomed, when their services are no longer required in it, are more apparent than real. Many departments of industry are closely allied, and all of them have many things in common; so that an industrious and intelligent workman who is thrown out of one has seldom much difficulty, provided he be so disposed,[1] in finding his way into some other department. And it is also to be observed, that improvements are seldom so rapidly introduced as to occasion the dismissal of hands; the necessary change being usually effected by the check given to the entrance of new hands into the business.

---

[1] This qualification must not be lost sight of. The disinclination of the hand-loom weavers to abandon an employment in which they are to a considerable extent their own masters, has done much to prolong the period of their transition.

But it is needless to insist farther on these points. The principal objections to the extension of manufactures depend on other considerations; and do not all admit of so conclusive an answer as those which refer to the improvement and extension of machinery.

Influence of factory labour on the intelligence and health of the work-people.

The fact of their being crowded together has been said to be exceedingly injurious to the work-people engaged in factories; and that, from their attention being constantly restricted, in consequence of the extreme subdivision of labour, to some very limited or petty operation, and the want of free air and proper exercise, they degenerate, both intellectually and physically, and become inferior to the agriculturists, and those who prosecute their business in the fields. But these consequences, though at first sight they seem to follow naturally from the circumstances, have happily not been realized, in so far, at least, as respects the mental powers of the work-people. Instead of becoming more contracted, their intellectual capacities seem, on the contrary, to have expanded with the greater subdivision of their employments. And how unexpected soever this result may be, it is, after all, only what a less prejudiced inquiry might have led us to anticipate. The many occupations which the husbandman successively carries on, and the perpetual changes in the weather, and in the growth and appearance of the objects about which he is engaged, occupy his attention, and render him a stranger to that *ennui,* and desire for external excitement, so universally felt by those employed in indoor routine businesses. This craving, on the one hand, and the few facilities for rational enjoyment on the other, is a principal cause of the dissipation in which the work-people are so prone to indulge. But it has other and less objectionable consequences. By working together, factory labourers have many opportunities, of which those employed in the fields are comparatively destitute, of discussing all manner of topics. Their intellects are sharpened by the collision of opinion. They desire to know what is going on in the world; and by each contributing a small sum, they obtain an ample supply of newspapers and other periodical publications, and sometimes form book-clubs. But whatever doubt may exist as to its cause, there can be none in regard to the superior information of the work-people employed in factories. We do not believe that they were ever less intelligent than farm-labourers. But, whatever may have been the case formerly, none will venture to affirm that they are so at present, or that they are "mere machines, without sentiment or reason." (Ferguson *On Civil Society*, p. 303.)

The objection made to manufactures on account of their alleged injurious influence over the health of the work-people in factories, is not so easily disposed of. In so far, indeed, as the question may be supposed to refer to adult males, there is no evidence to prove that factory labour, provided it be not excessive, is productive of injurious results. But it is otherwise with children, or young persons of both sexes, and perhaps also with certain classes of females. The former are never, and the latter are frequently not their own masters. And though there has been much exaggeration on the subject, still there is no room for doubt that the individuals referred to have been subjected to tasks, and confined for periods, unsuited to their age, sex, and strength. We, therefore, are disposed to approve of the policy which has been adopted of excluding children under eight years of age from factories, and of limiting the labour of young persons from eight to thirteen years of age to 6½ hours a-day, and of those from thirteen to eighteen years of age to 10 hours a-day. But we should object to any restrictions being laid on the labour of adult males, or of such adult females as are their own masters. The State is bound to protect those who cannot protect themselves; but none else. It may also, perhaps, lay down and enforce some easy regulations for the prevention of accidents in factories. But, speaking generally, the less it interferes in such matters the better. Work-people who are *sui juris* can never safely rely on the government, or on any one but themselves. The interference of the magistrate will be but a miserable substitute for that prudence and forethought which it is their duty to exercise, and which can alone secure their well-being.

Influence of factory labour on the well-being and opinions of the work-people.

Exclusive of the circumstances now mentioned, there are others connected with the growth of manufactures, in respect of which it is not easy to arrive at any definite conclusion, but which, nevertheless, deserve serious consideration. Without, however, attempting, to do more than glance at the subject, we may observe, that the tendency of manufactures appears to set strongly in favour of concentration; that is, to their being carried on in large establishments, belonging to a few great capitalists, where thousands of work-people are managed by a small number of overlookers. And in these establishments the lot of the labourers is apparently one of the least desirable. Their occupations are singularly monotonous, being little else than the endless repetition of the same set of precisely similar, and generally simple operations. It is alleged, too, that of the work-people in factories, probably not one in twenty, and certainly not one in ten, supposing they abide in them, can materially improve their condition, or rise to a higher station; and, though not the slaves of this or that master, they are, it is affirmed, the slaves of the factory system. But, while it must be admitted that these statements unhappily contain a good deal of truth, they are, notwithstanding, much coloured and exaggerated. It may be true that only a few of those employed in factories attain to independence, or even consideration; but as preferment in them, whatever may be its amount, is open to all, the great prizes which they offer, like those in a lottery, or in other occupations, attract crowds of competitors, and inspire them with a strong spirit of emulation, and with the hopes of success. In despite, however, of these and other countervailing influences, there seems, on the whole, little room for doubting that the factory system operates unfavourably on the bulk of those engaged in it. In some departments this may not be the case, but in the majority, and especially in those connected with spinning, weaving, and other merely routine employments, it is eminently so. It is certain, too, that the demand for the services of children and other young persons, and the ease with which factory labour may in general be learned, has had a powerful influence in depressing wages, and, consequently, in preventing the wonderful inventions and discoveries of the last half century from redounding so much to the advantage of the labouring classes as might otherwise have been anticipated. As compared, indeed, with the extraordinary progress made by the capitalists and employers of labour, the work-people can hardly be said to have made any very considerable advance, either in respect of their physical or moral condition. And hence the growth of unions and combinations, and of that discontent which is so very frequent among them. Their poverty, too, is rendered the more galling from the contrast which it presents to the wealth of their superiors, or of those with whom they are daily brought into contact. The latter, it is true, have generally sprung from the class to which they belong, and are mostly indebted for their greater riches to their greater genius, enterprise, and industry. But these circumstances being unknown to many, and speedily forgotten by others, they are said to owe their fortunes to chance or some lucky accident; and, except in peculiar instances, they are more generally, perhaps, regarded by those below them with feelings of envy or even ill-will, than as examples to be followed. This, of course, is not the case with the more generous, sanguine, and enterprising spirits in the workshops, who occasionally raise themselves to a level with their employers. But the great mass of factory work-people must be too conscious of their weaknesses and shortcomings to indulge in such anticipations. And in reality they have nothing before them but a life of continuous labour, cheered by few gleams of sunshine, and chequered principally by the recurrence of privations. Such being the case, can we wonder at the prevalence of that dissipation which is so much and so loudly complained of? On the contrary, the wonder is, that it is not a great deal more prevalent, and that discontent and disaffection are not more frequent and more widely spread.

Combinations are one of the favourite means to which work-people have had recourse of late years, to bring about an increase of wages, or a diminution of the hours of labour. But as we have already entered at considerable length, in the article COMBINATIONS, into an examination of their influence on industry and the condition of the labourer, it is needless to resume the inquiry in this place. We believe, however, that we are warranted in saying that it is very doubtful whether combinations to raise wages have ever been productive of any real advantage to the labouring classes; while it is certain that, on very many occasions, they have been exceedingly hostile to their interests.

This unsatisfactory state of things, which seems to grow necessarily out of the extension of manufactures, is apt to be seriously aggravated through the fluctuations to which they are subject from changes of fashion, the discovery of new methods of production, and the alterations which wars and other casualties not unfrequently make in commercial channels. It is true, indeed, that the extension and freedom of trade, by multiplying the relations of manufacturing and trading nations, renders them less dependent on circumstances affecting one or a few of their customers. But however much commerce may be extended, it is found that these as well as other nations mainly depend on a few countries for their principal supplies of the most necessary articles, while others afford the most advantageous outlets for their peculiar productions. A great manufacturing country is, therefore, exposed to vicissitudes to which it would otherwise be less liable; and hence, we may add, the expediency of its adopting a cautious and conciliatory course of policy, and of its avoiding unnecessary quarrels and contests with others.

If we be right in these statements, it follows that manufacturing eminence has, like many things else, its peculiar advantages and disadvantages. And though the latter are apparently of a very formidable description, they may, perhaps, be in a greater or less degree counterbalanced by the operation of circumstances of which we have not yet learned to estimate the influence.

Task-work.

The principle of association, in regard to which so much has been said, will never, we apprehend, be found to be productive of any sensible advantage to the labourers. (See on this subject the article WAGES in this work.) But it would be quite otherwise were the practice of task-work, that is, of employing labourers by the piece or job, to become more general. By exactly apportioning the reward to the skill and industry of the labourer, task-work takes away all temptation to idleness, and makes workmen put forth all their powers. The more enterprising become contractors on a small scale, as well as labourers; and from one step to another often raise themselves to independence, and sometimes to affluence. It were, therefore, much to be wished that the system should be introduced, in as far as practicable, into all sorts of industrious undertakings, but especially into those branches of manufacture in which the condition of the labourers is the least favourable. It would not fail to imbue them with new hopes and new energies; and would be constantly raising numbers of those that were most deserving to improved positions. We are indeed well convinced that nothing would do so much as the extensive introduction of task-work into factories, to dry up the existing sources of discontent; to give all classes—the servants as well as the masters—the same spirit; and to satisfy them that their interests are really identical.

Condition of females in factories.

The difficulty which females belonging to the labouring-classes experience in obtaining any more acceptable employment, is probably the principal cause that so many of them are found in factories. No doubt, however, the lightness of the labour, the little training required for its performance, and the power to leave them when one has a mind, are also powerful inducements to enter factories. But, however explained, the number of females engaged in them has increased from 195,508 in 1835 to 409,300 in 1856, of whom 25,982 were under thirteen years of age. The employment of so many females is a very important feature in factory economy, and is in many respects beneficial. It would be difficult, indeed, were the demand for their services in factories materially to decline, to provide them with other equally advantageous outlets. And yet the shutting up of great numbers of women in these establishments, and the close attention they have to give to their work, is productive of some results that are not a little injurious. Speaking generally, factory girls are very ill fitted for being housewives. They have little or no experience of their duties as such. The mill is their principal home; and however expert in the work they have to perform in it, they know little of anything else, and are most commonly ignorant, to an extent not easily to be imagined, of the arts by which their wages and those of their husbands may be best and most economically expended. The mischievous influence of this ignorance is too obvious to require being pointed out, and considerable efforts have latterly been made to lessen it by improving the education of girls, and instructing them in cookery, baking, sewing, washing, and other arts necessary to the wellbeing of their families. But though some improvement may be effected in the way now mentioned, it is, we apprehend, idle to expect that, however instructed, women employed in factories should generally make good wives and mothers. It is too much to expect that they should be able to attend at the same time to the mill and to their families. One or other is almost sure to be neglected; and the presumption is, that this will be the case with the latter rather than the former.

It is a curious circumstance that something like the factory system is now applied to the rearing of the children of the work-people engaged in factories; for receiving-houses (*creches*) are being established in the great manufacturing towns, where the mothers deposit their children on their way to the mills, and receive them again on their way back. And though in some respects a very considerable improvement, the adoption of this plan gives but a sorry idea of the state of the manufacturing population. Such, however, and so limited is the field for the employment of women in England compared with their vast numbers, that factory labour must be regarded, notwithstanding its many drawbacks, as having contributed materially to their welfare.

Duty of masters.

A great manufacturer, like a great landowner, has a vast deal in his power, and, with little loss to himself, may do, and sometimes does, a great deal of good to his work-people. The truth indeed is, that in promoting and rewarding those labourers who distinguish themselves by their industry and good conduct, and in checking, in as far as may be in his power, the idleness and vicious propensities of others, he is following a line of conduct that is highly conducive to his interests. But an enlightened and a generous master should do more than this. He should look upon his work-people as part of his family, should interest himself in their well-being, assist in providing schools for the education of their children, and forward any proper plan for improving their dwellings, for supplying them with good medical advice, and so forth. Those masters who can do much to promote the real interests of those in their employment, and who, notwithstanding, do little or nothing, lie under a heavy responsibility. They abdicate or abuse some of their most valuable privileges, and are culpable in more ways than one.

Owing to the facilities for obtaining supplies of skilled labour, and the convenience resulting from the vicinity of other establishments, factories may now, speaking generally, be more advantageously located in towns than in the country. This, however, has the disadvantage of making it comparatively difficult for the masters to inform themselves with respect to the habits and mode of life of those in their service. But this circumstance will not excuse that neglect of the interests of the work-people in towns which is so frequently evinced by their employers. The conduct of the former in the mill, the punctuality of their attendance, their cleanliness, and the way in which they perform their allotted tasks, will throw a great deal of light on their character. And those indices should not merely lead the master to advance the deserving, but it should, also, lead him to inquire into the modes of life and habits of the others. And it is not easy to estimate the influence that his advice, exhortation, and threatenings, might have over their conduct.

Whatever else education may do for the work-people, we do not believe that it will do what is expected by some; that is, that it will make factory-labourers contented with their lot. On the contrary, we are disposed to think that its effect will rather be the reverse of this, and that that will be one of its principal advantages. It is clear, indeed, that if it had the effect supposed, it would be in so far disadvantageous that it would, at one and the same time, weaken the motives for the introduction of those reforms into the factory system to which we have alluded, and impair the energies of the workmen, and their efforts to advance themselves.

It is plain, therefore, that it is no easy matter to cast the horoscope of the manufacturing system, to estimate the changes it may undergo, or its ultimate influence over the condition of those among whom it may be established. Much will depend on future contingencies, and much also on the operation of principles to which new combinations of circumstances will no doubt give rise. The hopes of some, and the fears of others, may at present predominate; but no just confidence can be placed in the speculations of either class; and the final results will be learned only by a distant posterity.

III. FACTORIES (ECONOMY OF).

Economy of factories.

By a factory, in a general sense, is understood any building or inclosure within which any branch of manufacturing industry is carried on. But in practice the term appears to be confined to buildings of an extensive description, fitted up with machinery, and suited for the prosecution of one or more branches of manufacture. Factories in which cotton is spun being mostly on a large scale, are generally called spinning mills; and others have peculiar names according to the nature of the business to which they are devoted.

The skill and judgment of the manufacturer are evinced in nothing more than in the proper construction and economy of factories. Their suitableness to the end in view, provided it be accomplished without any unnecessary expense, is one of the most important elements in manufacturing success. It may be laid down generally, that to insure this grand object, the machinery in factories should be of the best quality, and the labour to be performed distributed so that the strength and capacity of those employed may be exactly apportioned to the tasks they have to perform. And as any mistakes in regard to the selection of the individuals to be employed in factories, and more especially of those appointed to superintend the different departments, would be quite fatal to their success, we may be sure that everything that is practicable will be done to guard against their occurrence. But it would be idle to attempt to lay down any precise rules in regard to the economy of these establishments, seeing that all arrangements must be accommodated to the successive improvements in the arts, the species and command of the power to be employed, the price and supply of labour, and so forth. The extent also to which the different branches of industry may be most advantageously congregated into a single establishment, is entirely a practical question for the sagacity of the manufacturer, the solution of which must depend on its greater or less proximity to others, and a variety of other circumstances. Though the principle of the division of labour should never be lost sight of in the construction of factories, neither should it be carried to an extreme. In some very extensive and prosperous factories in the principal seats of the cotton trade, the various processes, from the carding, spinning, and weaving of the wool, to the bleaching and printing of the cloths, are carried on under the same roof. Generally, however, some of the processes that in these instances are performed in one, are distributed among different establishments.

Of late years the question in regard to the interference of the police in the construction of factories has been a good deal mooted. On the whole, we are inclined to think, that if confined within moderate and well-defined limits, it may be advantageous. In the smaller and inferior class of factories ventilation and cleanliness are apt to be neglected; and there does not appear to be any good reason why the police should not be permitted to see that these indispensable requisites for the health of the work-people are properly attended to, and to denounce their neglect. They may also be authorized to see that any peculiarly dangerous machine is properly fenced off, and to denounce or abate whatever can be fairly considered as a nuisance. But here, as in the case of the labourer, non-interference should be the rule, and interference the exception. The latter, indeed, is to be tolerated only when there is clear and unquestionable abuse.

Latterly it has been attempted to make factories consume their own smoke; but though this may be an expedient proceeding in the case of factories in towns or populous neighbourhoods, it is otherwise with those in the country or in thinly-peopled districts. There the smoke can do little or no injury.

Domestic manufactures.

Various branches of manufacture have, at one time or other, been wholly or partly carried on in the houses of the work-people. This was formerly the case with the spinning and weaving of wool, flax, &c., and it still continues to a considerable extent in the former department. These domestic manufactures, as they have been called, were supposed to be peculiarly advantageous, from their enabling the parties engaged in them to live in the country, away from the physical and moral contagion of great towns, and where they could now and then engage in the healthy labours of agriculture. But there was a good deal more of imagination than of reality in these representations. In some respects, indeed, if we look only at the labourers, the balance of advantage may have been on their side. They had, we may take for granted, in the country good air and good water; but at the same time their cottages have generally been of the meanest description; their children, who were made to assist their parents at the earliest possible moment, had seldom any opportunity of being educated; and the work-people themselves have most frequently been idle and slovenly. The attempt to combine the pursuits of husbandry with those of manufactures, or to assign to those engaged in the latter small portions of land which they were to cultivate at extra hours, has had the precise result that was to be anticipated; whether in England, Ireland, or elsewhere, it has proved to be a failure, and has been injurious alike to both departments. Before spinning mills were so much as thought of, and the linen trade of Ireland was wholly domestic, Arthur Young said,—"If I had an estate in the south of Ireland, I would as soon introduce pestilence and famine as the linen manufacture upon it." (*Travels in Ireland*, part ii., p. 120, 4to edition.) There cannot, in fact, be any material improvement either in agriculture or manufactures till they are separated and apportioned to entirely different sets of individuals. A good ploughman cannot be also a good artizan. Inferior workmen may engage indiscriminately in different occupations; but to attain to excellence in any one art or calling, it is indispensable that it should be the exclusive business of those by whom it is carried on. And such being the case, none need regret that the mixing up of agriculture and manufacturing employments has ceased to be regarded as favourable, and is now generally abandoned.

Still, however, certain varieties of what may be called domestic manufactures, or manufactures carried on in separate establishments on a small scale, continue to exist in a few circumscribed localities. Thus, the spinning and weaving of woollen yarn and cloth by power not being so extensively practised as in the cotton trade, the old hand-jenny and the hand-loom are in pretty extensive use in the district of which Leeds is the centre; and there, consequently, a variety of domestic manufacture keeps its ground. The parties by whom it is carried on have generally from two to six or more looms, and employ, besides their own families, more or fewer journeymen, according to the magnitude of their business. Formerly they were in the habit of carrying the wool in these little factories through all its stages, till it arrived at the state of undressed cloth. But for a considerable time past the domestic and factory systems have been so intermixed, that some of the processes in the manufacture are performed at public mills constructed for that purpose, but the cloth is almost wholly dressed and packed in Leeds.

Should the spinning and weaving of wool by power come to be perfected to the same degree as the spinning and weaving of cotton, the domestic manufacture now referred to will have to be abandoned; and this result is taking place. The processes for the spinning of wool by machinery are being perfected, and the number of power-looms employed in the weaving of wool has increased from 2045 in 1835 to 9439 in 1850, and 14,453 in 1856. The presumption consequently is, that the factory system is destined to become as preponderating in this as in other departments. The period of transition will, of course, be longer or shorter according to the progress of invention, the rate of wages, &c.; but of the transition being effected in the end, there can be no reasonable doubt.

Some departments of the hardware trade are also prosecuted in cottages, but they are of little importance. None but the simplest descriptions of machinery can be introduced into cottages or small establishments. Whenever, therefore, it is found that the work executed by their assistance may be executed more cheaply or better by means of more powerful and complex machinery, the former necessarily begin to be abandoned. And it is fortunate that their abandonment is attended by few or none of the mischievous effects by which it was formerly supposed it would be accompanied.

Domestic manufactures in Russia, &c.

Perhaps it is hardly necessary, seeing that this book is intended for the special use of Englishmen, to state that these conclusions, how applicable soever to Great Britain, France, the greater part of the United States, and other countries similarly situated, do not apply to countries with a severe climate, or to such as are very thinly peopled. In Russia, British America, Oregon, &c., the ordinary pursuits of agriculture can only be carried on for about five or six months in the year, or perhaps less, so that the peasants, if they did not engage in other employments while the land is covered with snow or bound by frost, would be idle for more than half their time. Hence in such countries the apportionment of employments to different individuals cannot be carried to anything like the extent to which it may be carried in more temperate climates; and the person who for one portion of the year is a farm labourer, is during the other portion a weaver, a carpenter, a smith, a shoemaker, or something, or, it may be, several things else. The peculiar situation of Russia makes this system be practised to a very great extent in that empire. The peasants are all artizans of one sort or other as well as husbandmen, and hence the surprising facility with which they turn from one thing to another.

In Russia, Hungary, Poland, and all imperfectly civilized countries, the cottages of the peasantry are not distributed over the surface, as in Britain, but are congregated into hamlets or villages. And it is a curious fact that these villages, instead of being addicted to many, generally confine themselves to some one occupation, exchanging their surplus products for those of the adjoining villages at the fairs so frequent in those countries, or by the intervention of pedlars or agents travelling from place to place. There is therefore in Russia a greater subdivision of employments than might perhaps have been expected; and the system seems to be well calculated for the peculiar circumstances under which the empire is placed.[1] In those provinces where the population is thinly scattered over the surface, and the villages small and at great distances from each other, the division of employments becomes less perfect, and the manufactures which are carried on from generation to generation, usually with little change, are altogether primitive and domestic.

But though, under such circumstances it would be idle to suppose that Russia should succeed in the finer branches of manufacture, or in those required for the wealthier and more refined portion of the community, there are certain branches, such as the manufacture of coarse linen and canvas, mats, leather, &c., in which she has peculiar and important advantages. And her real interests would be best promoted by opening her ports to the free importation of those articles in the production of which foreigners have a superiority; for this would give the most effectual as well as the most natural stimulus to the export of her raw products, which are the main elements of her wealth, and to those industrial pursuits in which the superiority is on her side.

Unluckily, however, this has not been hitherto the policy of the Russian government. Spinning and weaving mills, conducted on the plan followed in England, have been established at Moscow and elsewhere in Russia. And a great variety of factories have been set on foot by the nobles in different parts of the empire, the labourers in which are the slaves of the proprietors, employed for certain periods under a sort of *corvee* or statute-labour system. But notwithstanding the wonderful aptitude of the Russian peasantry to execute the tasks allotted to them, it is not to be imagined that factories carried on by compulsory and reluctant labour should prove successful; and, in point of fact, the products made in them are at once bad and dear, while the processes continue nearly stationary. And even the best managed factories, or those which are carried on by work-people, who are free on paying an *obrok* or tax to their lords, could not support themselves were they not protected by high duties on foreign fabrics. The home demand for their productions is inconsiderable. The great bulk of the population being supplied by domestic manufactures, their only dependence must be placed on the stinted demand of the upper classes resident in the few great towns, and on the export trade. And little or no stress can be laid on the latter; for, with the exception of some inconsiderable outlets along her Asiatic frontier, the chances are ten to one that the foreign markets are already supplied with cheaper and better articles.

---

[1] See *passim* the statements in regard to manufactures in the valuable works of Haxthausen and Tegoborski on Russia.

IV. LOCALITY OF MANUFACTURES.

Locality of manufactures.

The locality of manufactures depends principally on physical causes, but partly, also, on accidental circumstances. Among the former may be mentioned facility of commanding power in the shape of waterfalls or steam; proximity to the raw material, as in the case of the iron manufacture; and to the demand, as in the case of cabinetmaking, brewing, and other businesses carried on in great cities; and so forth.

Production of iron.

During the first half of last century, when the iron trade of England was of very trifling dimensions, it was partly carried on in Kent, Surrey, and Sussex,[1] not so much on account of the abundance of the ore in these counties, as of the furnaces being readily supplied with fuel from their numerous woods and copses. And notwithstanding the repeated interference of the legislature in their behalf, the woods referred to, as well as those in other parts of the kingdom, were so much exhausted in 1740-50, when the make of iron did not exceed from 17,000 to 18,000 tons a-year, that had not other means been discovered of smelting the ores, the business must have been strangled in its cradle. This contingency had, indeed, been long obvious; and in the latter part of the reign of Elizabeth, and the early part of that of James I., efforts were made, partly in the view of preventing the destruction of timber, and partly of turning small coal (which was reckoned of no value) to account, to employ the latter in the making of iron. And these efforts were so far successful, that in 1621 Lord Dudley took out a patent for the manufacture of iron by means of pit-coal, he being able to produce by his process about three tons of iron a week! But though his lordship's patent was expressly excepted from the act of 1624 (21 Jac. i., c. 3) for the abolition of monopolies, his works were destroyed by an ignorant rabble, and he was well nigh ruined by his efforts to improve and perfect an invention which has since proved to be of such transcendent utility.[2] It appears, in consequence, to have been for a lengthened period almost entirely forgotten, and in 1740 or thereabouts it was only introduced into a single work in Coalbrookdale. But since that epoch, or rather since 1760 or 1770, when it was brought into general use, the manufacture has steadily increased; and of late years its progress has been so very extraordinary, that the make, which amounted in 1830 to about 678,000 tons, amounted in 1855 to no fewer than about 3,325,000 tons! At this moment the produce of iron in Great Britain is supposed to be about equal to the produce of all other countries, including the United States. In the latter the annual make may at present (1857) amount to about 850,000 or 900,000 tons.

We may mention, in farther illustration of the extension of the iron trade, that, exclusive of the vast additional quantities consumed at home, the real value of the exports of iron and steel, wrought and unwrought, has increased as follows, viz.:—

1842	L.2,457,717
1845	3,501,895
1850	5,350,056
1854	L.11,674,675
1855	9,472,886
1856	12,986,674

Next to Lord Dudley's invention, the progress of the iron manufacture has been principally owing to the improvement of the steam-engine, the invention of the process of puddling, and the introduction of the hot blast.

It is needless, perhaps, to add, that the works in Kent and Surrey have been long abandoned, and that iron is now produced exclusively in those districts in which coal as well as iron ore is most plentiful.

The vast increase in the production of iron has been mainly occasioned by its greater cheapness, which has enabled it to be applied to a great many purposes to which it would be quite unsuitable were it much more expensive. But it is said, that this greater cheapness has led to a deterioration of the quality of iron, as well as to the increase of its supply. And such, we believe, is the case. It is not clear on what the superiority of some descriptions of foreign iron depends, whether it be the preferable quality of the ore, the use of wood as fuel, the slower processes generally followed, and the greater care taken in the manufacture. But whatever the causes may be, the fact of a superior article being produced is unquestionable. It is material, however, to bear in mind that the better article costs a proportionally higher price; and as an inferior and cheaper article such as is generally made in Great Britain, suits the great majority of purposes quite as well as the other, our manufacturers have done wisely in adapting their supply to the general demand. When superior iron is required, it can be produced on its price being paid, or it can be imported. Like any other description of produce, it may be had of all qualities and at all rates. But its manufacture in England would never have attained to anything like its present value and importance, had not cheapness, rather than excellence, been the grand object of our producers.

Restrictions on the importation of iron.

Seeing that an abundant supply of iron at a moderate price is indispensable to success in the arts, it might have been expected that those countries anxious to attain to eminence in manufactures, would not fail to adopt every means that might tend to lessen its price and increase its supply; and we incline to think that if bounties on importation were ever justifiable, it would be in the case of iron. But, by a singular inconsistency, the reverse of this usually takes place; and nothing is more common than for states to impose high duties on iron brought from abroad, or to prohibit its importation, at the very moment that they are labouring to bolster up manufactures. It is needless to dwell on the contradictory nature of such a policy; which, however, is that of France, Russia, and most other countries. Owing to the scarcity of coal, and other circumstances, their producers cannot furnish iron except at a comparatively high price; and to encourage them to persevere in a disadvantageous business, government lays heavy duties on foreign iron; or, in other words, does all that it can to raise the price and deteriorate the quality of the instruments and machines principally employed in industrious undertakings! It is said by M. Tegoborski, that owing to the restraints on its importation, the scarcity and high price of iron in Russia are such that the horses of the peasantry are seldom shod, and that their ploughs, harrows, and other agricultural implements are made wholly of wood. Whereever a *felo de se* policy of this sort is adopted, it would be idle to expect that industry should make any progress. Our ascendancy in manufactures will not be in much peril so long as it is generally acted upon.

---

[1] The railings round St Paul's Cathedral were cast in Sussex.

[2] The *Metallum Martis* of Dud Dudley, Lord Dudley's son, in which an account is given of the circumstances connected with his lordship's invention and the patent, was published in 1665. Having become very scarce, it has recently been reprinted, with some additional matter illustrative of the early history of the trade.

Mills commonly situated in towns.

When Sir Richard Arkwright's inventions began to be applied to the spinning of cotton, spinning-mills were most frequently erected in situations which had a considerable command of water-power, though in other respects they might be far from convenient. But the discoveries of Watt relieved the cotton-spinners from the necessity of seeking power at the sacrifice of other advantages. And while the steam-engine enabled them to command an unvarying amount of power (which was seldom the case with water), it also enabled them to build their mills in towns and other localities where labour and other things could be procured with the greatest advantage.

The extensive employment of steam in the greater number of factories is the reason that they are now mostly found in districts where coal is abundant. Owing, however, to the greater economy in the use of coal, one ton of which is now made to furnish as much power as $2\frac{1}{2}$ or 3 tons did some years ago, and the facilities afforded for its conveyance by means of railways and steam navigation, businesses established in districts where it is wanting, may, from the better training of the work-people, and the possession of the market, be able to maintain for a lengthened period their former ascendency. But the greater cost of coal or power, or an inconvenient situation, is still, notwithstanding all that has been done to lessen it, a considerable and perpetually operating disadvantage. And the desire to escape from its influence seldom fails in the end to tempt some of those who are newly entering into the trade to establish factories where the motive power may be had at less cost. And when the example has once been set, and a population familiar with the business got together in the new locality, it will most likely be wholly transferred thither, unless, as may very possibly happen, the advantages on its side should be otherwise neutralized.

Influence of accidental circumstances in determining the locality of manufactures.

But though command of power and readiness of access be powerful requisites to the success of most manufactures, the localities in which peculiar businesses are established would seem to depend as much on accident as on anything else. Why, for example, should Manchester be the great seat of the cotton, Birmingham of the hardware, Bradford of the worsted, and Leeds of the cloth trade? We apprehend that no better answer can be given to this question than that, from accidental or inappreciable circumstances, the businesses referred to happened to be early established in these towns, and that their situation having been found to be peculiarly well fitted for the improved processes of later times, they have preserved their early superiority. Had they been situated in districts without coal, or comparatively inaccessible, their early proficiency, though it might have enabled them to struggle for a while with the greater advantages enjoyed by their competitors in other districts, would not have been sufficient to secure their continued lead, or even existence. They must, like the Kentish iron-works, have been in the end abandoned. But having the good fortune to possess, in addition to early and peculiar skill in their respective trades, all the means and appliances required to secure their further advancement, their progress has been continuous and extraordinary, and their supremacy is at present more undisputed than at any former period.

Manchester is said, in Leland's *Itinerary*, written in the reign of Henry VIII., to be "the fairest, best builded, quickest, and most populous town of Lancashire" (*Itin.* v., p. 94, edit. 1769). But Leland says nothing of manufactures; and we are indebted for the earliest notice of the cotton trade of Manchester to a tract by Lewis Roberts, published in 1641, in which he says that "the inhabitants buy cotton wool in London, which comes from Cyprus and Smyrna, which they work up into fustians, vermillions, dimities, and other stuffes."[1] But it is to be observed that the wool only of these fabrics consisted of cotton, the warp being then, and long after, formed wholly of linen yarn, which was partly brought from Ireland; and that the importations of cotton yarn and raw cotton were then, and down to a comparatively late period, quite inconsiderable. Such was the late and feeble beginning of that manufacture which an unprecedented combination of discoveries here and abroad has since so prodigiously increased.

The superiority of Birmingham in the manufacture of cutlery and hardware was as conspicuous in the days of Henry VIII. as at present. Leland says,—"There be many smithes in the towne that use to make knives and all manner of cutting tools, and many loriners that make bittes, and a great many naylors; soe that a great part of the towne is maintained by smithes whoe have their iron and sea cole out of Staffordshire." (*Itin.*, vol. iv., part ii., p. 114.)

Sheffield has been long famous for its cutlery. Chaucer says of the miller of Trumpington,—"A Sheffield whittle bare he in his hose" (*Millar's Tale*, l. 3930). Leeds and Bradford are both referred to as manufacturing towns by Leland and Camden.

Linen manufacture in Belfast and Dundee.

The growth of the linen manufacture in Belfast and Dundee, both of which are destitute of water-power and of coal, may appear perhaps to militate against the previous statements; but when rightly considered, this will not be found to be the case.

The spinning and weaving of flax was established in the farm-houses and cottages of Ulster by settlers from Scotland, in the reign of James I., and it was improved by refugees expelled from France after the revocation of the Edict of Nantes. This domestic manufacture, which has been the theme of much undeserved eulogy, was perpetuated, down to a recent period, by the continued subdivision of the land; the parcels occupied by families not being sufficient to afford them employment. While this system prevailed, it was customary for agents from Belfast and other towns to visit the country fairs and markets to buy up the raw or brown webs, which were mostly conveyed to the former, where, after being bleached, lapped, finished, and packed, they were exported partly to Britain and partly to foreign parts. In this way Belfast became the principal seat of the linen trade of Ulster, and its merchants were rendered familiar not only with the various details of the home trade, but also with the various circumstances affecting the supply and demand for linens in the countries to which they were exported.

Matters went on in Ulster nearly in the way now stated till between 1825 and 1830. In the meantime, however, the machinery that had been first applied to the spinning of cotton began to be applied to the spinning of flax; and after this had been effected, some enterprising parties, among whom the Messrs Mullholland were the first, constructed flax-mills in Belfast, with the view of supplying the cottage weavers with yarn. The speculation proved eminently successful. Precisely the same causes that had given the first great stimulus to mill-spinning in Lancashire and other parts of England were in operation in Ulster. The processes of spinning and weaving were most frequently carried on together in the same cottages; but the families of the weavers being unable to furnish them with sufficient quantities of yarn, the latter were in the habit of collecting additional supplies from spinners and others not attached to looms. A good deal of the weavers' time was thus frittered away; and being frequently idle, or only half-employed, they were apt to contract bad habits. Under these circumstances we need not be surprised to learn, that no sooner had the mill-spun yarn come into the market, than it was eagerly sought after by the weavers and their employers; and being cheaper than that spun by the common hand-wheel, and the supply regular and abundant, the latter was in no very lengthened period entirely thrown aside. Many of the families who had previously been engaged in spinning emigrated to Belfast, where they found employment in the flax-mills that were multiplied on all sides; while the greater number of those who continued in the country are now employed in the embroidery of muslins, which are sent in vast quantities to be sewed in Ulster, from Glasgow, the grand seat of the muslin trade.

---

[1] "Treasure of Traffic," p. 73, in *Select Tracts on Commerce*, reprinted for the Political Economy Club in 1856.

The excellence of the bleaching in the country contiguous to Belfast is one of those circumstances to which the progress and present prosperity of its manufacture is in no inconsiderable degree to be ascribed. Whether it be occasioned by some peculiarity of the water, the humidity of the atmosphere, or the mildness of the winter, is unknown. But of the pre-eminence of Ulster in this art there can be no question. So much is this the case, that English power-loom fabrics and Belgian brown webs are regularly sent to Ulster to be bleached.

Such seem to be the main features in the progress of the linen trade of Belfast. Its situation made it the natural emporium of the business, and it had attained to eminence as such before the command of natural power was supposed to be of much consequence. Now, however, this is found to be of primary importance. And as coals for the mills must be brought from Ayrshire and Cumberland, and the machinery used in them from Manchester, these circumstances operate as a serious drawback on Belfast, and it remains to be seen whether she will be able permanently to maintain her present ascendancy. The superiority of her bleaching grounds, the skill of her work-people, who are familiar with all the details of the business, and the greater cheapness of their labour, have all helped to turn the balance in her favour. But the latter circumstance was a good deal more decided a few years since than at present; and despite its influence, the cotton-mills which were constructed previously to the flax-mills have had to be given up. It is probable, too, that the progressive employment of power-looms in the weaving of linen, into which they are already very extensively introduced, may eventually operate to the prejudice of Belfast. But in a case of this sort, where so many unforeseen contingencies may arise, little stress can be safely laid on any conclusions as to the precise results that may be expected to take place at some future period. It is plain, however, that in the present state of manufacturing industry, the disadvantages that attach to Belfast and other places similarly situated, are of a rather formidable description. They may no doubt be fully countervailed by peculiar advantages; but if not, they can hardly fail in the long run to sap the foundations of their prosperity.[1]

Most part of the statements now made with respect to the linen trade of Belfast apply with but little alteration to that of Dundee. At an early period the manufacture of coarse linens for home use and for exportation was carried on in the towns of Dundee, Arbroath, Montrose, &c., and in the villages and hamlets of the adjacent districts. Some portion of the raw material was raised at home, but by far the greater portion was imported from abroad, especially from Russia. Dundee early took the lead in this business, and became the principal centre of the trade. For a lengthened period the manufacture was bolstered up by means of bounties and prohibitions. But notwithstanding their assistance, it made but a slow progress till after mills for the spinning of the yarn were introduced. Since, then, however, its advance, despite the repeal of the bounty, has been quite extraordinary, and it is at present in a prosperous condition.

In the case of Dundee, as in that of Belfast, early acquaintance with the trade, a convenient situation for the exportation of the manufactured goods and the importation of the raw material, and a good harbour, gave her advantages of which her citizens have availed themselves with an energy and enterprise which have seldom if ever been surpassed. Still, however, the want of water-power and of a supply of native coal are considerable impediments to the progress of the manufacture; and the fair presumption would seem to be, that in the end they must have the same influence here which we have seen they may be expected to have in Belfast. It may, perhaps, be worth while to add, in corroboration of this view of the matter, that the manufacture of cottons, which was also attempted here as well as in Belfast, has long ceased to exist.

We subjoin some statements illustrative of the extent, progress, and location of the factories for the production of textile fabrics.—(*See Table on next page.*)

Cotton.

Of the 2046 cotton factories in England and Wales in 1856, no fewer than 1480 were situated in Lancashire; Manchester being the metropolis of the trade. The remaining factories were principally situated in the West Riding of Yorkshire, Cheshire, and Derbyshire.

The cotton trade of Scotland is mostly restricted to the counties of Lanark and Renfrew, and that of Ireland (which is inconsiderable) to Antrim. But while the business has of late years been very greatly extended in England, it has been nearly stationary in Scotland, and has fallen off in Ireland.

Embroidery of muslins.

The embroidery of muslins, a branch of the cotton trade which is highly deserving of attention, was commenced in Scotland about 1825, and is almost wholly carried on by Glasgow houses. It is now of first-rate importance, its increase not having been surpassed by that of any other branch of industry, and equalled by very few. At present (1857) one Glasgow house employs in its central establishment in that city no fewer than 500 men and 1500 women, besides employing from 20,000 to 30,000 females, partly in Ayrshire and other parts of Scotland, but principally in Ireland! In all, above fifty houses are engaged in the trade; and the total sum paid as wages to females in the western parts of Scotland, and in Ireland, is believed to amount to L.750,000 a-year. The embroidery is entirely executed by hand, the attempts to execute it by machinery having failed, or been found to be too expensive. The

webs to be embroidered pass between engraved cylinders, driven by steam-engines, which mark in faint lines the embroidery to be executed, and they are then sent to agents, who distribute them among the peasantry, who are paid by the piece, or job. It is not easy to exaggerate the advantages resulting to the female part of the population from this employment. After being embroidered, the webs are returned to Glasgow, where they are bleached and dressed, and sometimes made up into different articles. A large proportion of the goods are exported to the United States and Canada.[1]

The value of the exports of all sorts of cotton goods and yarn in the undermentioned years has been as follows, viz.:—

	1842.	1850.	1856.
Cotton goods,	L.13,907,884	L.21,873,697	L.30,219,099
Yarn,.........	7,771,464	6,383,704	8,065,671

The subjoined table, taken from the carefully-compiled and comprehensive statement of Messrs Holt and Company of Liverpool, dated 31st December 1856, shows in a very striking manner the progress and principal circumstances connected with the cotton manufacture since 1816:—

---

[1] We are indebted for most part of this information to our learned and excellent friend, Dr Strang, chamberlain of Glasgow.

N.B.—Messrs Holt and Co. estimate the average weight of the packages imported in 1856 at 423 lbs. per bag Upland; 454 lbs. Orleans and Alabama; 330 lbs. Sea Island; 181 lbs. Brazil; 308 lbs. Egyptian; 385 lbs. East Indian; and 175 lbs. West Indian.

Wool.

Of the 1282 woollen factories in England and Wales, 807, or nearly two-thirds of the whole, belong to Yorkshire. The trade has for some years past been increasing very rapidly in the West Riding, while it has been declining in most other parts of the kingdom.

Worsted.

The worsted manufacture, which has latterly been very greatly increased, is principally concentrated in Yorkshire, Bradford being its centre. Recently, however, a considerable number of worsted factories have been constructed in Worcester.

We borrow from the report of the jury on woollen and worsted manufactures in the Great Exhibition of 1851, the following details illustrative of the progress of the trade in Bradford:—"The first factory in Bradford was built in 1795; but it was not until thirty years afterwards that the power-loom was introduced, and considerably later before its use became general. From the year 1825 the worsted manufacture has made most rapid and unprecedented progress. Up to that period, and for some years afterwards, all the goods were made from wool alone; but about the year 1834 manufactures of worsted weft and cotton warp were first brought forward, and gave a great impetus to the trade. This was still further increased by the introduction in 1836 of the wool of the alpaca, an animal of the llama tribe, inhabiting the mountain ranges of Peru. Considerable difficulties were at first experienced in the working of this material; but they were ultimately overcome, and the alpaca manufacture now ranks as a very important branch of the worsted trade. About the same time, or shortly afterwards, mohair, or goat's wool, from Asia Minor, was brought into general use in the West Riding of Yorkshire, and many beautiful fabrics were produced from it. Silk also, in combination with wool, alpaca, and mohair, has been largely used. Improved machinery has been devised; more rapid processes of manufacture adopted; and the results of all these improvements, and the introduction of these new materials have been—the opening of new branches of industry, the quadrupling within thirty years of the number of work-people employed, and the production of an immense variety of fabrics for the purposes of clothing and furniture.

"The rapid progress of the trade may be illustrated by a reference to the town of Bradford, which is the centre of the manufacture, and the great market where its productions are disposed of. The population of the borough has increased in the following ratio, viz.:—

In 1801 it was	13,264
„ 1821 „	26,309
„ 1841 „	66,718
„ 1851 „	103,782

"At the beginning of the present century there were only three mills in Bradford; there are now (1851) upwards of 160.

"The following returns show the extent of its present manufacturing operations. They comprise the parish of Bradford and the village of Bingley:—

Number of spindles	355,792
Number of power-looms	17,294
Moving power, steam (horse-power)	3,884
Do. water do.	134
Children employed under 13 years of age,—Males	1,469
Do. do. Females	1,729

Males from 13 to 18	3,426
Do. above 18	5,951
Females above 13	21,280
Total persons employed—Males	10,846
Females	23,009
Total	33,855"

And since 1851 the progress of the manufacture has been quite as rapid as previously.

On the whole, it appears that the total number of persons employed in the worsted factories in Bradford had increased in the interval between 1835 and 1854 no less than 384 per cent.[1] It is worthy of notice, too, that the demand for adult labour has been proportionally greater than for juvenile labour, that is, for hands under eighteen years of age. This result is believed to be owing partly to adults being exempted from the statutory regulations in regard to factory labour, and partly to the more extensive use of highly improved machinery.

Flax.

Yorkshire is also the principal seat of the English flax trade; but the business has been for several years in a backward state in England. At present (1857) it is more vigorously prosecuted in the parts of Ireland adjacent to Belfast than anywhere else in the United Kingdom.

Silk.

Since 1850 the manufacture of silk has increased more rapidly than that of any other textile fabric. It belongs almost wholly to England, and principally to the counties of Chester, Derby, and Lancaster.

The great improvement and extension of this manufacture of late years is particularly deserving of attention, inasmuch as it affords a very striking illustration of the advantages of competition. Previously to 1826 the importation of foreign silk goods was prohibited, and an enormously high duty was laid on foreign thrown silk. The consequences were such as might have been anticipated. The manufacturers and throwsters, trusting to the protection thus unwisely given to them, made no effort at improvement, and instead of taking the lead, like their neighbours, in most other businesses, they were far behind their foreign rivals. In consequence, the manufacture was limited in the extreme; the parties engaged in it were every now and then subjected to the severest vicissitudes; and the smuggling of foreign silks, despite all that could be done to prevent it, became a flourishing business. At length, in 1826, Mr Huskisson, struck with the evils of this state of things, determined to abate them by introducing an entirely new system, that is, by allowing foreign silks to be imported at a duty of 30 per cent. *ad valorem*, and reducing at the same time the duties on raw and thrown silk. And notwithstanding the many confident predictions to the contrary, the trade has since continued progressively to extend itself on all sides. The manufacturers, seeing they could no longer depend for support on custom-house regulations, became aware of the necessity of exertion; old and worn-out machinery was replaced by the newest and most improved; processes were simplified and perfected; and it is admitted on all hands that the manufacture made greater advances between 1826 and 1840 than it had done in the course of the previous century.

In 1845 Sir Robert Peel reduced the 30 per cent. *ad valorem* duty on foreign silks when imported to 15 per cent.; and while this wise and liberal measure went far to suppress the smuggling that previously prevailed, it gave a new stimulus to the invention and ingenuity of the manufacturers. The business has in consequence been very largely extended; so much so, that the value of the exports of silk goods, which in 1842 amounted to only L.590,189, had increased in 1856 to L.2,966,938,—a memorable and signal example of the powerful and beneficial influence of that free commercial policy which Sir Robert Peel did so much to introduce.

Exclusive of the return of factories, &c., previously referred to, similar returns were obtained in 1835, 1838, and 1850. The following comparative statements deduced from these returns show the progress of the factory system in so far as it applies to textile fabrics since 1838:—

Number of Factories in the United Kingdom in 1838, 1850, *and* 1856, *exhibiting their Increase per cent. from* 1838 *to* 1856.[2]

Description.	Factories in			Per cent. increase from 1838 to 1856.
	1838.	1850.	1856.	
Cotton Factories...	1819	1932	2210	21·495327
Woollen „ ...	1322	1497	1505	13·842662
Worsted „ ...	416	501	525	26·201923

Silk ...	268	277	460	71·641791
Total ...	4217	4600	5117	21·342186

N.B.—A return was obtained of the number of factories in 1835, but being evidently incomplete, no good purpose would be served by quoting it.

Inasmuch, however, as the size and efficiency of factories has been greatly increased since 1838, the mere increase of their number affords no just criterion of their increased capacity of production. This will be evident from the following returns:—

Account of the Horse Power, distinguishing between Steam and Water, employed in the Factories of the United Kingdom in 1838, 1850, *and* 1856, *with their increase per cent, from* 1838 *to* 1856.

---

[1] Report of Mr Redgrave, factory inspector, October 1854.

[2] These returns are taken from the Report of the inspectors of factories for the half year ending 31st October 1856, but we have added the column of per centages.

Account of the Total Number of Persons employed in the Factories of the United Kingdom in 1835, 1838, 1850, *and* 1856, *with their Increase per cent. from* 1838 *to* 1856.

Fabric.	Hands employed in				Per cent. increase from 1838 to 1856.
	1835.	1838.	1850.	1856.	
Cotton ...	219,386	259,104	330,924	379,213	46·355517
Woollen..	55,461	54,808	74,443	79,091	44·305575
Worsted..	15,880	31,628	79,737	87,794	177·583154
Flax......	33,212	43,557	68,434	80,262	84·268889
Silk.......	30,745	34,303	42,544	56,137	63·650409
Total ...	354,684	423,400	596,082	682,497	61·194378

Bringing these proportions together, we have the following

Account, exhibiting the Increase per cent. in the Number of Factories in the United Kingdom, and in the Amount of the Power used and the Number of Hands employed in them, from 1838 *to* 1856.

Fabric.	Increase per cent. 1838 to 1856.		
	Factories.	Power.	Hands.
Cotton	21·495327	62·419945	46·355517
Woollen......	13·842662	25·629335	44·305575
Worsted......	26·201923	107·692307	177·583154
Flax	6·377551	65·226801	84·268889
Silk	71·641791	52·955082	63·650409

These accounts set the increasing size and efficiency of factories in the clearest light, and strikingly illustrate the statements already made in regard to their tendency to increase. Notwithstanding the apparent contradictory nature of the allegation, the truth is, that the factory system may in reality be increasing when the number of factories is diminishing. Thus in Scotland the number of cotton factories fell off from 192 in 1838 to 152 in 1856, while the horse-power employed in them rose during the same interval from 8340 to 9971.

At an average of the United Kingdom, the number of spindles in a factory was,—

	In 1850.	In 1856.
Cotton..............................	14,000	17,000
Worsted............................	2,200	3,400
Flax	2,700	3,700

The average number of spindles kept in motion per horse power was—

	In 1850.	In 1856.
In cotton factories..................	275	315
Worsted..............................	86	102

In woollen and flax factories the proportions were nearly the same.

Weaving factories have been supposed to form an exception to the tendency to the concentration of the business in large establishments. But this result is apparent only, and is occasioned by the extensive introduction of power-looms into the worsted, flax, and silk trades, the factories for which are not upon so extensive a scale as those for cotton-weaving, to which they were first applied.

Regulations in regard to the quality of manufactured goods.

It is perhaps hardly necessary to advert to the regulations intended to secure the quality of manufactured goods that were formerly so very general. These are now almost everywhere abolished; and it appears to be generally conceded that in this, as in most other things, the free competition of the producers is the only principle on which any reliance can ordinarily be placed for securing superiority of fabric, as well as cheapness. Wherever industry is emancipated from all sorts of restraints, those who carry it on endeavour, by lessening the cost or improving the fabric of their goods, or both, to extend their business; and the intercourse that subsists among the different classes of society is so very intimate, that an individual who should attempt to undersell his neighbours by substituting a showy and flimsy for a substantial article, would be very soon exposed, and be obliged to reduce its price to its proper level. Cheaper articles are often advantageously substituted for those that are dearer; but it is not possible to substitute inferior for superior articles, and maintain them in the place of the latter, without making a proportional reduction in their price. A manufacturer has not only the eyes of his customers but of the trade upon him; and while any scheme for diminishing expense excites their competition, all attempts at fraud are most commonly ruinous to the future prospects of the party. A character for honesty and fair dealing is, in the arts as in everything else, of the highest value.

Wherever public marks or regulations are introduced, their tendency is to weaken or extinguish that spirit of invention and enterprise which is indispensable to manufacturing eminence. When a man's muslins, or silks, or linens, come up to the official standard, he has no motive to improve them still more. Whereas, when there is no standard other than the public taste, he has, in the more as well as in the less advanced stages of his art or craft, the same desire to attract demand and to extend his dealings; and this he can only do by reducing the price of his goods, or suiting them still better to the real or imaginary wants of his customers or of the public.

It is obvious, too, that the plan of subjecting manufactured products to examination by government agents must lead to all sorts of abuse. When this baneful practice used to be carried on, the higher marks were frequently fixed, not to the best goods, but to those whose producers were best able to promote the interests of the examiners.

Brands in the herring fishery.

Consistently with what is now stated, we have to regret that when the bounty on herrings was repealed in 1830, government did not also abolish the "Fishery Board," and the officers and regulations it had appointed and enacted. So long as the bounty existed, it was proper that those who claimed it should be subjected to such regulations as government chose to enforce. But after its repeal, we see no reason why the fishery should not have been made perfectly free, and every one allowed to prepare his herrings as he thought best. It is said, indeed, that were there no inspection, frauds of all sorts would be practised; that the barrels would be ill made and of a deficient size; that the fish would not be properly packed; that the bottom and middle of the barrels would be filled with bad ones, a few good ones only being placed at the top; that there would not be a sufficiency of pickle, &c. But it is obvious that the reasons alleged in vindication of the official inspection which it is proposed to continue in the case of the herring fishery, might be alleged in vindication of a similar inspection in almost every other branch of industry. It is, in point of fact, utterly worthless. It is an attempt on the part of government to do that for their subjects, which they can do better for themselves. Supposing the official inspection and brand were put an end to, the different curers would have brands of their own; and it would be their object to improve and perfect the quality of their fish, that they might dispose of them more readily and at a better price. It is no answer to this reasoning to say, that at present herrings with the official brand are prefered to those without it. The fact of its having been long in use, and held forth as a guarantee of goodness, has created, without any just ground, a prejudice in its favour. But when it is abolished, and official *prestige* has ceased to influence opinion, competition will do its work. The fish of those curers that are found to be best and cheapest will be sure to be in the greatest demand; while all attempts at fraud will not fail to drive those by whom they may be made from the market. Of the many thousand barrels of pork, and the many hundreds of thousands of bales of cotton, annually exported from the United States, those that are falsely packed make an all but inappreciable fraction; indeed, such a thing is very rarely heard of. And yet no one supposes that there is any very material difference between the *morale* of the packers of pork and cotton, and those of fish. Were the official brand abolished, the latter, like the former, would very soon find that their advantage would be most effectually promoted by their fish being not only above suspicion but of the best quality.

Cases in which examination may be useful.

But though, speaking generally, the abolition of the examination system has been of the greatest advantage, there are a few departments which are so very peculiar that it may perhaps be beneficially enforced in them. Fire-arms, for example, cannot be readily tested by ordinary persons; and as any defect in their construction is most dangerous, we are disposed to agree with those who think that it would be good policy to prohibit the sale of all muskets, fowling-pieces, pistols, &c., that have not been tried and approved at a public proof-house. If a man buy a barrel of inferior herrings, or a piece of bad cambric or calico, no great harm is done, and he will not return to the shop where he was cheated. But it is quite another matter if he buy a defective fowling-piece. In this case he may lose his life as well as his money; and hence the advantage of the previous examination.

Precisely the same reasoning applies to the case of chain-cables and anchors. It is but seldom that they can be tested by the buyers. And as the safety of the ship and crew may be compromised by the cable having a single bad link, or the anchor being improperly constructed, it appears expedient that they should be subjected to an efficient test before being used.

The imposition of the stamp on plate has been defended on the like grounds; that is, on the difficulty of determining whether an article be of the standard quality or not, and the consequent expediency of affording a guarantee to the purchaser. It is, however, contended that in this case (and the same reasoning applies, though in a less degree, to the case of fire-arms and cables) the security is far from complete; and that the forgery of the stamps, and their transference from one piece of plate to another, of inferior quality, make them rather a cover to than a security against fraud. On the whole, however, we have little doubt that they are useful. The forgery of a stamp being reckoned in the public estimation a much more serious offence than the substitution of a spurious for a genuine article, the fair inference is, that it will be more rarely committed.

It is not uncommon for the brands or marks of eminent manufacturers to be adopted abroad, and sometimes even at home, and affixed to wares of an inferior character. The total prevention of practices of this sort needs not, we fear, be looked for. Still, one should think that such police arrangements might be adopted as would prevent such practices at home, and such engagements entered into with foreign countries as might go far to hinder them from becoming injuriously prevalent in those countries; more especially as it is not difficult, by the intervention of the press, to expose these mal-practices, and make them redound to the disgrace of those by whom they are adopted.

Manufacturing by government.

To begin at this time of day to argue in favour of the greater cheapness of products manufactured by individuals working on their own account, and reaping all the advantages of superior skill and economy, as compared with those manufactured by agents employed by government, may perhaps be considered a mere waste of time. In as far as authority, argument, and experience can settle a question of this sort, it has been settled a thousand times over.

And yet, how singular soever it may appear, proposals are every now and then made to governments by individuals, who are bold enough to promise that, provided they are employed for the purpose, they will engage to produce such and such articles of better quality, and at lower prices than they can be bought for in the market. And though it be natural enough to expect that such offers should occasionally be made, especially by those who have broken down in the management of their own affairs, it is, we think, not a little surprising that they should be listened to, and still more that in some cases they should be acted upon.

It is alleged in vindication of such conduct, that though the greater cheapness and efficiency of articles produced under a system of open competition be true generally, the case in question, whatever it may be, is an exception. And this is pretended to be proved by estimates of the cost of the articles to be produced, which are not really, in one case in five hundred, worth the paper on which they are written. In such estimates some most important items of expense, and some important considerations, are wholly lost sight of, or are carefully kept in the background. Thus, suppose it were proposed that a government should manufacture paper, cloth, muskets, or other articles for itself, it would be told that the raw material would cost so much, the labour so much, and that the produce could be turned out at some two-thirds or less of the sum for which it could be bought. But every one who knows anything of the matter, knows that a vast number of other items besides raw material and labour enter into the cost of manufactured goods. The mills and factories in which the articles are produced cost large sums; and the articles must be charged not only with the interest of the sums laid out in the construction of the mills, &c., but with a farther sum to insure them against fire, to keep them in working order, and to form a sinking fund to replace them when they are worn out. But this is not all. Inventions are constantly being made; so that the most efficient machinery of to-day may be the least efficient in a year or two, and must consequently be changed at whatever cost. And not only this, but the goods or articles produced in 1856 or 1857, and which were then supposed to be the best of their kind, or the most suitable for the end in view, may be in a short while superseded by others, for the production of which the machinery now in use may be totally inapplicable. And besides mills and machinery, governments which are foolish enough to enter into such undertakings must have men to work them. And what are they to do with them when they have no work on which to employ them, or when they become old, or are maimed by accident? They cannot turn them adrift; they must maintain them in one way or other; and the cost of their maintenance will be a part, and in the end no inconsiderable one, of the cost of the articles. But it is needless to insist farther on these and the many similar considerations which will occur to the reader. Those who really believe that products manufactured by government agents can be furnished as cheaply as those manufactured by private parties, may believe, on quite as good evidence, in the truth of Mormonism, spirit-rapping, or any other quackery or folly of the day.

But it is said, that though the goods manufactured by governments may not be so cheap, they will be of better quality than those made by private parties, and that there will be less chance of inferior articles being mixed with them. But we deny that such is the case. Let governments select the best patterns for the articles they want, and they will obtain them quite as good, or better if it be desired, under a system of open competition. If not, the blame does not rest with the makers, but with the overlookers or parties appointed to receive and test the articles. If the latter be qualified for their duty, and *do* it, the makers must do theirs or be ruined.

It has been more than once suggested to the Russian Government to introduce the system of private enterprise and economy into the manufacture of arms carried on at Tula. Select, it has been said, the best models of the arms to be manufactured; appoint skilful and competent parties from England and elsewhere to see that the articles produced are in all respects equal to the patterns, and offer their production to the lowest bidder. We have been assured that were this system adopted, the cost of the establishment would be reduced a half or more; that the quality of the muskets and other arms would be decidedly improved; and that there would be much greater facilities than at present for introducing new inventions and improvements.

Permanency of manufactures.

All speculations in regard to the future condition of any great department of industry must necessarily be of a very vague and doubtful character. They involve so many considerations which are all liable to perpetual changes, the causes and consequences of which it is impossible to appreciate beforehand, that but little dependence can be placed even on those that are most carefully elaborated. But, were we called upon to express an opinion on the subject, we should say, that provided the public tranquillity and the free disposal and security of property be maintained intact, there is nothing to make it be supposed that the British manufacturing system has arrived at, and much less that it has passed, its zenith.

It has been said by Hume, that "manufactures gradually shift their places, leaving those countries and provinces which they have already enriched, and flying to others, whither they are allured by the cheapness of provisions and labour; till they have enriched those also, and are again banished by the same causes." (*Essay on Money.*)

This is one of the few instances in which Hume has allowed his better judgment to be swayed by popular prejudice. There has not, in truth, been any transfer of the kind to which he refers. The manufactures of the ancient world, which were almost entirely domestic, were not transferred to, but were destroyed by the barbarians; while in modern times the industry of Spain and of the Italian cities of the middle ages fell a sacrifice to the influence of the Inquisition, the establishment of an oppressive system of government, and the discovery of the route to India by the Cape of Good Hope. We have yet to learn that a single instance can be pointed out in the history of the world where, security and other things being about equal, manufactures and trade have left a rich to settle in a poor country. The persecutions of Philip II. and the Duke of Alva, and not the greater poverty of Holland and Zealand, made the manufacturers and merchants of Ghent, Bruges, and Antwerp, seek an asylum in them and in England.

Even in their earliest stages, or when manufactures are principally carried on by the hand, we doubt whether a poor has any advantage over a rich country. Wages may be nominally lower in the former, but the probability is, that they are really dearer. It was said by an excellent judge (Arthur Young) who visited Ireland in 1776-79, that labour in Essex was cheaper at 2s. 6d. than in Tipperary at 5d. a day. Estimated by the work done in a given time, which is the only just standard, labour is uniformly cheaper in rich and industrious than in poor and idle countries. And unless the latter have other and more substantial advantages on their side, their apparently low wages will do them no good and their neighbours no injury.

But if such be the case in the earlier stages of manufactures, the lowness of wages, were it real, and not nominal, has infinitely less influence in determining their locality when they are highly advanced. That is then mainly determined by the command of power, of capital, and of skilled labour. Where these are wanting, or obtainable only in an inferior degree, improved manufactures cannot exist. And as these are enjoyed by this country in the highest perfection, the inference is, that we shall continue, so long as we preserve our security and our freedom, to maintain our manufacturing ascendancy.

Dependence on the United States for supplies of cotton.

The circumstance of the cotton manufacture being dependent for by far the larger portion of the raw material on importations from the United States, has recently been made the subject of a good deal of discussion. It has been said that this state of things is not a little hazardous; that in the event of anything occurring to involve us in hostilities with the States, or that might injuriously affect the growth of cotton in them, our manufacturers might be exposed to the greatest difficulties, and the wellbeing of a large class of our people seriously compromised. It is alleged too, that, independently of the considerations now mentioned, it may be doubted whether America will be able to meet the increasing demand for cotton; and hence it is contended that we should encourage its growth in India, Africa, and elsewhere. But we are not disposed to attach much weight to these considerations. The Americans would suffer as much as we should do, or more, by laying an embargo on the exportation of cotton, which measure, were it really attempted, would inevitably bring about a disruption of the Union. And unless some rash and ill-advised proceedings take place with respect to the slaves, of which there is no prospect, there is every reason to anticipate a very large increase in the produce of cotton in the United States. It is to be observed, too, that should the demand increase for a while faster than the supply, the consequent increase of price would give a new and powerful stimulus to production, which would probably in the end sink prices lower than ever. Neither, we confess, have we much faith in the speculations of those who say that the supplies from India may be largely augmented. Indian cotton is mostly of inferior quality, and the tenure of the land and the character of the natives present formidable obstacles to its extended cultivation. And if little needs be expected from India, far less should be expected from Africa. The prospects of the manufacture will be bad indeed when it comes to depend in any considerable degree on African imports.

On the whole, it would seem that this is a case in which the *laissez faire* and *laissez passer* policy is the most proper that can be followed. The interests of the merchants and manufacturers will lead them to find out the best markets in which to buy the raw material, as well as those in which to sell the finished articles. A rise of a few cents per pound in the price of cotton will do ten times more to stimulate its production in the most suitable localities than all the speeches at all the meetings that will be held on the subject during the next half century. (J. R. M.)

MANUZIO, Aldo Pio (or *Manutius*), the first of those justly celebrated printers who were in Italy what the Stephens afterwards became in France and Geneva, was born in 1447 at Bassiano, in the Roman state. He was educated at Rome, and after completing his course of study, repaired to Ferrara to study Greek under Guarini, a learned professor of that language. In 1482 he quitted Ferrara, then threatened with a siege by the Venetians, and retired to Mirandola, where he was received with distinction by the all-accomplished Pico. Yielding to the entreaties of Alberto Pio, he then went to Carpi, where he was soon joined by Pico, the uncle of the prince. In the course of the year 1488 he repaired to Venice, a city which, from its position, its commerce, and the literary taste of its inhabitants, appeared the best suited for his design. His first object was to make himself advantageously known, and, with this view, he commenced by giving public instructions in Greek and Latin; but in the meantime he was very busily occupied in organizing his printing-house; and at length, in 1494, he published the poem of *Hero and Leander* in Greek and Latin, which was followed by the *Grammar* of Lascaris, that of Theodore Gaza, and the works of Theocritus, Apollonius, and Herodian. But it was the publication of the works of Aristotle which placed Manuzio in the first rank of printers. This edition alone, though less correct than the greater part of those which followed it, would be sufficient to earn for Manuzio the gratitude of posterity, and to justify all the commendations which have been bestowed upon him. Before this time the greater part of books had been printed in the folio or largest size; Manuzio, however, conceived the happy idea of publishing a collection of the Latin classics in a more convenient form, and with this view he had a character cast in imitation (it is said) of the hand-writing of Petrarch, and employed it for the first time in the impression of his Virgil which appeared in 1501. This character, long afterwards known by the name of *Aldine*, and now by that of *Italic*, was designed and cut by Francesco of Bologna. The multiplicity of works which now issued from his presses having rendered it impossible for one individual to superintend the impressions, he had recourse to the assistance of some learned men, his personal friends; and out of this association of persons, united in one common object, he formed the Aldine Academy, whose short duration did not prevent it from attaining great celebrity. It reckoned amongst its members Bembo, Erasmus, Battista Egnazio, and Andrea Navagero, who every year burned, in honour of Catullus, a copy of Martial; the monk Bolzani, the first who wrote in Latin the principles of Greek grammar; Alcyonio, who is accused of having destroyed the only manuscript of Cicero's treatise *De Gloria*, after having transferred its finest passages to one of his own works; the Greek Musurus Demetrius Chalcondylas, who published the first edition of Homer; and Aleandro, afterwards cardinal. In 1506 war obliged Aldo to withdraw from Venice; and during his absence his goods were pillaged and his domains seized. In 1507 he resumed his typographical labours, and subsequently formed a partnership with Andrea Toresano d'Asola, his father-in-law, of which Aldo was constituted the head. He was on the point of publishing a Bible in three languages, when he was in 1515 removed by death, at the age of sixty-eight, leaving his son Paolo to prosecute his father's designs.

The Greek editions which issued from the presses of Aldo are less correct than either the Latin or the Italian editions; but it should be remembered that he had frequently only a single manuscript, incomplete or half effaced, from which to reproduce a work, and that the conservation of many is entirely owing to his laborious patience. The mark of his press, it is well known, is a dolphin coiled round an anchor. Besides the prefaces, and the Greek or Latin dissertations with which he enriched most of his editions, Manuzio was the author of several works, which would of themselves have been sufficient to insure to him a distinguished place amongst the learned men of his age, if he had not been the most celebrated printer it produced. Of these works the most important are,—*Rudimenta Grammatices Linguæ Latinæ*, Venice, 1501, in 4to; *Grammaticæ Institutiones Græcæ*, 1515, in 4to; *Dictionarium Græco-Latinum*, 1497, 1524, in folio; *De Metris Horatianis*, a little work often reprinted during the sixteenth century; *Scripta Tria longe rarissima denuo edita et illustrata*, Bassano, 1806, in 8vo. The Abbé Morelli is the editor of this collection, which contains a poem of Aldus, entitled *Musarum Panegyris*, in two little pieces addressed to the Prince of Carpi. The original edition in 4to, without date, must have appeared before 1489. Manuzio translated from Greek to Latin the *Grammar* of Lascaris, the *Batrachomyomachia*, the *Sentences* of Phocylides, the *Golden Verses* of Pythagoras, and the *Fables* of Æsop and of Gabrias (Babrius). (See *Life of Aldus Manutius the Elder*, by Unger, augmented by Geret, Wittenberg, 1753, in 4to; also his Life by Manni.) (J. B—E.)

Manuzio, *Paolo*, son of the preceding, was born at Venice in 1512, and after the death of his father remained under the care of his maternal uncle, Andrea Toresano. After his uncle's death in 1529, the printing establishment was re-opened in 1533, for the common benefit of the heirs of Aldo and Andrea d'Asola, with Paolo at its head. In imitation of his father, he sought the assistance of learned men, of whose counsels he availed himself; published new editions, particularly of the Latin classics, much more correct than the preceding ones; and enriched them with prefaces, notes, and indexes, the usefulness of which now began to be felt. On the erection of the Venetian Academy in 1558, Paolo Manuzio was appointed professor of eloquence and director of the academical press. On the dissolution of this institution in 1561, a letter from Cardinal Scripandi induced Paolo to repair to Rome, in order to superintend the impression of the works of the Fathers. The first work which proceeded from the new printing establishment was a small treatise of Cardinal Pole, *De Concilio et Reformatione Angliæ*, dated 1562. He died on the 6th April 1574. During the last years of his life his presses had begun to decline, yet Paolo Manuzio, as a printer and editor, was equal to his illustrious father; and his works place him in the rank of the best critics and most polished writers of his age. These were,—*Epistolarum libri xii. Præfationes, &c.*, Venice, 1580, in 8vo; *Lettere Volgari divise in quattro libri*, ibid. 1560, in 8vo; *Degli Elementi e di loro notabili Effetti*, ibid. 1557, in 4to; *Antiquitatum Romanarum liber de Legibus*, ibid. 1557, in folio, with an ample index; *Liber de Senatu Romano*, ibid. 1581, in 4to; *De Comitiis Romanorum*, Bologna, 1585, in folio; *De Civitate Romana*, Rome, 1585, in 4to. These four last treatises have been inserted in the *Thesaurus Antiquitatum Romanarum*, tom. i. and ii. Manuzio translated into Latin the *Philippics* of Demosthenes, Venice, 1549, 1552, in 4to; and he published Commentaries on the Familiar Letters of Cicero, the Letters to Atticus, Brutus, and Quintus; and the Orations, as well as Scholia, on the oratorical and philosophical treatises of the same author.

MANZANARES, a town of New Castile, Spain, capital of the partido of its own name, in the province of Ciudad Real, 98 miles S. of Madrid. Situated in a vast plain 1882 feet above the sea level, it enjoys a serene sky and salubrious climate. The small river Azuel flows near it, and the high road of Andalucia passes through it, forming its main street. The houses are mostly well built, with open courts, covered in summer with an awning. To the S.E. of the town is the ancient castle called De Peñas Borras, with wall and fosse; it was repaired and garrisoned during the war of independence. Besides a grammar school there are six other schools in the town, an hospital, and a recently erected parish church of modern Gothic architecture. The country around is perfectly flat, and quite destitute of wood and water, so that the soil, though fertile, requires careful irrigation; and the want of fuel is supplied with rye-straw, manure, olive, and vine cuttings. The productions of the district are wheat, rye, anise, saffron, potatoes, wine, and oil. A good deal of sheep and horned cattle are reared, as well as mules for plough and carriage. Of manufactures, the town contains four of linen cloth, as many of woollen, besides several of soap and brandy; and lime and tile kilns. It is rather noted for its excellent carriage-makers and workers in iron. A considerable number of the inhabitants are carriers, conveying grain, wine, oil, and oranges, &c., to Madrid, Andalucia, and Valentia. There is a market every Thursday. Pop. (1845) 9060.

MAPES, Walter (or *Map*, which, according to some, is the proper orthography), one of the most noted writers of Latin poetry during the reign of Henry II., was born on the borders of Wales about the middle of the twelfth century. After studying at the university of Paris, Mapes returned to England, where, joining himself to the court, he became a great favourite of Henry II., who esteemed him alike for his extensive learning and courtly manners. This attachment on the part of the king gained for Mapes various ecclesiastical preferments, being made canon of the cathedral churches of Salisbury and St Paul's; and after the successive enjoyment of many other dignities and benefices, was ultimately created Archdeacon of Oxford in 1196. He is supposed to have died about the year 1210. Our information respecting Mapes is chiefly drawn from the *Speculum Ecclesiæ* of his intimate friend Geraldus Cambrensis. (See the Camden Society's edition of *The Latin Poems commonly attributed to Walter Mapes*, edited by Thomas Wright, 4to, London 1841.)

"This genial archdeacon," as Warton calls him (*Hist. of Eng. Poetry*, vol. i., p. cxxvi., 1840), is generally supposed to have been the author of the greater part of the Latin poetry belonging to the latter half of the twelfth century. His vein was witty, festive, and satirical; and he seems to have been endowed with a decided taste for gay, elegant literature. The admirers of middle-age romance recognise him as the author of an important part of the cycle of King Arthur and his knights. The Cistercian monks had the misfortune to encroach on his territory and rights on some occasion, which so keenly roused the resentment of the jovial poet that he kept up a satirical fire against them, both in prose and verse, during the remainder of his life. A considerable number of the poems constantly and unhesitatingly attributed to Mapes, appear in the MSS. under the name of *Golias* or of *Golias Episcopus*. That this was a fanciful appellation given to the imaginary and burlesque representative of the clerical order there can be no doubt. The *Goliardi* are well known, as Mr Wright shows, to have been a riotous and loose class of clerical buffoons, who lived by practising their jests and ribaldry at the tables of the richer ecclesiastics. And while a skilful satirist of the clerical vices would, perhaps, find wider scope for the exercise of his function by assuming the attitude of a *Golias* than by any other mode of attack then open to him, it is nevertheless somewhat singular that Giraldus, who knew Mapes well, was not only led to believe that *Golias* was the real name of the author, but also that, in the very book (*Speculum Ecclesiæ*) in which he praises his friend Mapes so warmly, he takes occasion to censure these satirical verses in no measured terms, and to speak of their author with great severity. But, however this may be explained, there can be no doubt that these verses were ascribed to Mapes at a very early period. His name appears attached to the MS. of certain of these poems in the fourteenth century; and in several copies, belonging to the fifteenth century, of the *Apocalypsis Goliæ*, the most celebrated poem of the class, and still preserved in the Bodleian Library, Mapes is said to be the author; yet Mr Wright expresses strong doubts as to Mapes being the author of any of them. He accordingly, in the volume already referred to, has arranged the "poems bearing the name of Golias," those "attributed to Walter Mapes," and others "of a similar character, but not directly attributed to Walter Mapes," into separate classes. Of the first class, the most celebrated are the *Confessio Goliæ* and *Golias de Conjuge non Ducenda*,—the former containing the famous old drinking song of the "jovial toper," consisting of a number of leonine verses, commencing,—

> "Meum est propositum in taberna mori:
> Vinum sit appositum morienti ori," &c.

Besides gaining the epithet of "The Anacreon of the Twelfth Century," as Lord Lyttelton styles him, Mapes was likewise an industrious prose writer both in the Latin and Anglo-Norman languages. The only remains now known of this species of Mapes' literary labours are,—a treatise entitled *De Nugis Curialium*, edited by Thomas Wright, from the Bodleian MS., for the Camden Society, London, 4to, 1850; and a tract entitled *Valerius ad Rufinam de non ducenda Uxore*. The former is a very curious and interesting production, consisting of severe attacks on the vices of monasteries and courts, monastic stories, fairy legends, graphic notices of Welsh manners, and unceasing tirades against Cistercian monks.

MARACAYBO, Maracaibo, or Nueva Zamora, a town of Venezuela, in South America, capital of the province of the same name, is situated on the W. shore of the strait connecting the Lake of Maracaybo with the sea, 175 miles E.N.E. of Santa Marta, and 320 W. by N. of La Guayra; N. Lat. 10. 41., W. Long. 71. 40. The town is situated on a dry and sandy soil; and the houses are for the most part built of wood, and are thatched with reeds. This gives the town a mean appearance, and renders it very subject to fires. The only public buildings worthy of mention are,—the parish church (an elegant edifice), a chapel, a Franciscan convent, and an hospital. The harbour is deep, but there is a shifting bar at its mouth which prevents large vessels from entering; the anchorage is safe, however, being sheltered by three islands, called San Carlos, Zapara, and Bajo Seco, on each of which stands a castle for its defence. The town carries on a considerable trade, being the principal port for the provinces of Merida and Truxillo, and some of the districts of New Grenada. Cocoa, coffee, honey, sugar, tobacco, ropes, &c., are brought from the interior to Maracaybo, and are thence exported by foreign vessels to other countries. A considerable number of ships are built here. The inhabitants are chiefly employed in nautical pursuits, and are said to form excellent sailors. Many of them also find employment in tending the large herds of cattle which are bred in the neighbourhood. The climate of Maracaybo is oppressively hot; and in the summer season earthquakes are frequent, as well as violent thunder-storms, accompanied with torrents of rain. The province of Maracaybo extends round the lake of the same name, and is low, flat, and unhealthy. Area, 33,082 square miles. It is inhabited chiefly by natives; and had in 1854 a population of 59,311. Pop. of town 14,000.

Maracaybo, *Lake* or *Lagoon of*, the largest sheet of water in South America, being nearly 100 miles in length, and 80 in breadth at the widest part, lies between 9. and 10. 40. N. Lat., 71. and 72. 25. W. Long. This lake is of an oval form, communicating with the sea by means of a narrow channel, 46 miles in length, and varying from 4 to 14 in breadth. It would be navigable for the largest vessels were it not for a shifting bar at the mouth of the strait, over which there is only about 14 feet of water.

The waters, by reason of the numerous rivers which flow into the lake, are fresh and sweet; but towards the northern extremity, especially during the prevalence of N. winds, they are somewhat brackish. The total number of rivers that fall into the lake is said to be 105 perennial streams, and 400 which are dry during some part of the year. Of the former, the principal are,—the Catatumbo, the Zulia, the Escalante, and the Metatan. The shores of the lake are for the most part barren, and during part of the year the whole of its banks are inundated to the distance of 10 or 20 miles. On the N.E. there is a remarkable mine of mineral pitch, which sends out in the night such a brilliant phosphoric light as to serve as a guide to the navigators of the lake, and hence it is called the Lantern of Maracaybo. The lake is not subject to tempests of any great severity; and it abounds in fish and water-fowl. It was first entered by Ojeda and Vespucci in 1499, who gave the name of Venezuela, or Little Venice, to the surrounding country, by reason of the appearance of the Indian villages built on piles driven into the lake, which reminded them of Venice.

The Gulf of Maracaybo, which is also called the Gulf of Venezuela, is an inlet of the Caribbean Sea, having its entrance between Cape San Romano and Point Espada, a distance of 60 miles. It is about 75 miles in length from N. to S., and 150 in breadth. It contains several small islands, and communicates at the S. with the Lake Maracaybo.

MARAGHA, or MARAGA, a town in the province of Azerbijan, and the capital of a district, is situated 50 miles S. by W. of Tabrecz, 10 miles E. of the Lake Urumiah, and 305 miles W.N.W. of Teheran. It stands close to a small river which flows into Lake Urumiah, and here crossed by two bridges built in the eleventh century. The town covers a large extent of ground by reason of the extensive gardens which it contains, and which are extremely beautiful and productive, being watered by canals which intersect the town. Maragha is surrounded by walls, with towers, and contains a large and elegant bazaar, extensive public baths, and the tomb of Holaku, one of the princes of the line of Jenghis Khan. On a mountain in the vicinity are remains of an observatory, built by this monarch for the use of Nazer-a-Deen, a famous eastern astronomer. Pop. about 15,000.

MARANHÃO, MARANHAM, or SAN LUIZ, a town in Brazil, capital of a province of the same name, is situated on a narrow tongue of land on the W. coast of the island of Maranhão, 300 miles E. by S. of Para, Lat 2. 3. S., Long. 43. 50. W. It is built on an uneven surface, and consists of two parts, of which one, called Bairro da Praia Grande, extends along the shore close to the edge of the water; while the other, called Bairro de N. Senhora da Conceiçao, lies further inland. In the former part the houses have generally a very handsome appearance, being for the most part built of sandstone, two storeys high, and furnished with balconies. The streets, however, are generally uneven and irregular. In this part of the town there are several squares, the principal of which is surrounded by the governor's palace, the Jesuit's college, the town-hall, and the prisons. Besides these, the most important public buildings are the bishop's palace and the theatre. Each part of the town has a parish church; besides which, there are several other churches and chapels, and four convents. The back part of the town consists of small houses surrounded by gardens. The educational establishments comprise, a lyceum or college, schools of navigation and commerce, and various other schools. There is also a botanic garden and an English cemetery, laid out with much taste. The harbour of Maranhão is secure, but the entrance is difficult, by reason of a sandbank to the N. of the town, to the E. and W. of which there are deep and good channels. The trade of this place is very considerable. Brandy, wine, oil, flour, linen, hardware, and other European articles, as well as spices, drugs, &c., from the East Indies, are imported; while the exports consist of cotton, rice, caoutchouc, horns, hides, isinglass, sarsaparilla, &c. The whole trade of the north-eastern provinces of Brazil passes through Maranhão, as it is the most considerable seaport on that coast.

The island of Maranhão is of an oblong shape, about twenty miles in length by 12 in breadth. It is difficult of access, on account of the rapidity of the stream by which it is separated from the mainland. This stream is called the Rio de Mosquito, and is shallow, and about 100 yards wide. It terminates in two large bays, the Bahia de San Joze and the Bahia de San Marcos. The island is low and swampy, but fertile and well inhabited; and it contains, besides the town, several small villages.

The province of Maranhão is bounded on the N. by the Atlantic, on the E. by Pianhy, on the S. by Goyaz, and on the W. by Para. It lies between 1. 20. and 10. 50. S. Lat., and 41. 20. and 48. W. Long. The surface gradually slopes from the elevations in the S.W. towards the N.E.; and the principal rivers are the Parnahiba, which forms its eastern boundary, the Mearim, and the Itapicuru, all of which flow in the same direction. The only lake of any importance is the Mata. A great part of the province is covered with primeval forests, and the districts near the coast are fertile and very productive of cotton and rice. Iron, lead, and antimony are found in the province, but have not been mined in any great quantities. The principal towns, besides the capital, are Alcantara and Cachías. The area is 94,900 square miles. Population of the province (1851) 390,000, of the town 36,000, and of the island 40,000.

MARANS, a town of France, department of Charente-Inferieure, near the union of the Sevre-Niortaise and the Vendée, about 13 miles N.E. of La Rochelle. The country in which it stands, having been recovered from the sea, abounds with salt marshes, and is intersected by canals. The town is well built, and has a good bridge over the Sevre, which is navigable here for vessels of 100 tons. A canal has been recently constructed, by means of which ships of 300 tons can come up to the town. The trade is thriving, and consists principally of corn, wine, brandy, hemp, flax, timber, and salt. Pop. 4670.

MARASH, a pashalik of Asiatic Turkey, is bounded on the N. by that of Sivas, E. by Diarbekir, S. by Aleppo, and W. by Karamania, and lies between 36. 3. and 38. 30. N. Lat., and 36. and 38. 40. E. Long.; greatest length 130 miles, greatest breadth 105 miles. This country belongs to the basins of the Euphrates and the Jyhoon, the former of which forms its eastern boundary, while the latter rises near its centre, and flows through it in a S.W. direction. With the exception of the valleys of these rivers the district is entirely mountainous and wooded. It is crossed in the centre from W. to E. by the Taurus ridge, and also by the Antitaurus on the N., and the Durdun-Tagh on the S. The climate is mild, and the country is well adapted for pasturage. The capital is Marash, on the Jyhoon, 60 miles N.E. from the sea. Pop. of pashalik 248,000.

MARAT, JEAN PAUL, was born at Baudry in Neuchatel in 1744. After passing some time in the study of physical and medical science, he resolved to quit his native country and go in search of a wider sphere of activity. We find him accordingly in Edinburgh in 1774, supporting himself by giving lessons in French; and about the same time, his first publication, *The Chains of Slavery*, written in English, made its appearance. This work he afterwards translated into French, and published at Paris in 1792. His second publication, *De l'Homme, ou des Principes et des Lois de l'Influence de l'Ame sur le Corps, et du Corps sur l'Ame*, appeared at Amsterdam in 1775, and had the honour of being subjected to the polemical sarcasm of Voltaire, who undertook to refute it in the *Gazette Litteraire*. Marat still continued to pursue his physical inquiries in a somewhat fitful and irregular manner, and produced his *Recherches Médicales sur l'Electricité* at Paris in 1784. But he was not destined to succeed in this department. His morbid ambition and immoderate vanity scorned to have his upward progress as a scientific reformer checked by the patient observation and laborious experiment requisite to wring from nature her simplest secret. He nevertheless kept writing and publishing his empty paradoxes with surprising activity and boldness, furious at any one who dared to contradict him. But writing and rage failed to supply Marat with the means of subsistence, and we accordingly find him ere long in the streets of Paris, a needy vender of quack medicines. This position he exchanged in 1789 for that of veterinary surgeon at the D'Artois stables. Such had been the antecedents of Jean Paul Marat when the flames of the Revolution broke out in France. He flung himself with wild energy into the heart of this fearful movement, and gained for himself a name of infamy and shame. Marat had tried his hand at political philanthropy in 1787, in his *Plan de Legislation Criminelle;* but his regular political career commenced with the issue of his journal *Le Publiciste Parisien* on the 12th September 1789, shortly after the promulgation of the "rights of man." He afterwards exchanged the title of this paper for that of *L'Ami du Peuple*, a publication which soon acquired a fearful celebrity. This periodical was filled with the most violent denunciations against the court, the ministers, the Assembly, the National Guard, and, in short, against all the constituted authorities of society. These writings of "The People's Friend," read aloud every evening at the squares and public places of Paris, captivated the attention, and excited the passions of the needy and the turbulent. In October 1789 Marat joined the club of the Cordeliers, founded by the celebrated Danton. Having proposed, to the horror of the Assembly, to hang the 800 deputies on 800 trees of the Tuilleries, commencing with Mirabeau, Marat was hunted from one wretched den to another, till the imprisonment of the royal family, and the formation of the new municipality by the republicans on the 10th August 1792; when, emerging from his obscurity, the "People's Friend," arrested and imprisoned the *suspects*, and as a member of the Committee of Public Safety, signed the circular which exhorted the whole of France to imitate Paris, and massacre the so-called aristocrats. On being returned by Paris as a deputy to the National Convention, Marat was denounced in the assembly for having advocated in his paper the guillotining of 270,000 persons as fit objects of public vengeance. He not only admitted the charge, but defended it with great confidence, and with an air of sincerity, as the most effective method for saving the innocent, and for appeasing the people of France. His persuasive tongue not only silenced the angry clamour of the Convention, but even converted their rage into pity, and their shrieks into shouts of applause for "The Friend of the People." Whereupon Marat drew forth a pistol, and placing it to his head, said, if they had passed the accusation decree he would have blown out his brains. The Girondins had long been the objects of Marat's most virulent hatred, and he used every effort for their proscription. This party succeeded in summoning their relentless adversary before the revolutionary tribunal, but he was acquitted, as a matter of course, and carried in triumph by the populace back to the Convention. He soon after assumed the dictatorship, sounded the alarm on the 31st of May 1793, and witnessed the downfall of the Girondins, an event which he only survived till the 13th of July, when the assassin's knife of Charlotte Corday, a young Norman lady, who found access to his squalid apartment, put an end to his atrocities, and "did France a great service." (See Corday.) His death, however, was only hastened by a few days, for he was already, says a historian, "ill of revolution fever,—of what other malady this history had rather not name." He was living in a state of want and wretchedness, for it had never been his aim to amass wealth. He on one occasion sold his bed to enable him to publish his journal; and even when he had reached the summit of power, he continued to reside in a mean apartment with the wife of his printer, who is said to have loved him. After his death he was regarded as a martyr of liberty, and almost adored by the Jacobins. He had Pantheon honours and a public funeral decreed him. The dust of Mirabeau had to make way for him, and his heart was enshrined in a golden urn.

MARATHON, a city of Greece, on the E. coast of Attica, situated in a plain of the same name, is said to have been founded by Xuthus, who married the daughter of Erechtheus, and to have derived its name from the hero Marathon. Originally it constituted, along with three other cities, the district of Tetrapolis; but when that district was incorporated by Theseus into the state of Attica, Marathon, as the most important of the four cities, gave its name to the neighbourhood. Here Eurystheus was defeated and slain by Iolaüs the Heracleid; and here Theseus slew the furious bull, the pest of the plain (Str. viii.; Ovid. *Met.* vii. 433). But Marathon is chiefly famous as the battle-field on which the Athenians, in 490 B.C., defeated the Persians, and vindicated the independence of Greece (Herodot. vi. 102.) A monument to the memory of Miltiades, and the two tumuli that covered the slain of the Athenians and Platæans respectively, stood on the field in the time of Pausanias (i. 32). The former of the tumuli, about 600 feet in circumference and 30 in height, is still seen standing in the centre of the plain, about a mile and a half from the shore. (For a minute account of the plain of Marathon, see Colonel Leake's *Demi of Attica*, vol. ii.)

MARATTA, Carlo, the last celebrated painter of the Roman school, was born at Camorano, near Ancona, in 1625. He went a poor boy to Rome when only eleven years of age; and at twelve recommended himself so effectually to Andrea Sacchi by his drawings after Raffaelle in the Vatican, that he took him into his school, where he continued twenty-five years, that is, until his master's death. His graceful, dignified, and beautiful ideas occasioned his being generally employed in painting Madonnas and female saints, and procured for him the name of *Carlo delle Madonne.* From the finest statues and pictures he made himself master of the most perfect forms and the finest positions of heads, which he sketched with equal ease and grace. He has produced a noble variety of draperies, artfully managed and richly ornamented. He was inimitable in adorning the heads, in the disposal of the hair, and the elegance of his hands and feet, which are little inferior to those of Raffaelle himself. In his younger days he etched a few prints with spirit and correctness, and had the famous engraver Jacob Frey for his pupil. It would be tedious to recount the celebrated paintings executed by this great artist. Besides the famous picture of Daphne, painted for Louis XIV., he made several admirable portraits of popes, cardinals, and other persons of distinction, from whom he received the highest testimonies of esteem, as he likewise did from almost all the monarchs and princes of Europe. He died at Rome in 1713, in the eighty-eighth year of his age. See Lanzi.

MARAZION, or Market Jew, a market-town of England, county of Cornwall, on the slope of a hill on the coast of Mounts Bay, 18 miles W.S.W. of Falmouth, and 280 W. by S. of London. The town has a parish church and places of worship for Wesleyan Methodists and Baptists, a national school, an endowed school, and several charitable institutions. The trade is principally in iron, timber, and coals, which are imported for the use of the mines; and the inhabitants are chiefly employed in the tin and copper mines in the neighbourhood. Market-day Saturday. Opposite the town is St Michael's Mount, a small rocky island about a mile in circumference, and accessible at low water by means of a narrow causeway. In the middle ages it was much resorted to by pilgrims, and had a priory of Benedictine monks. The climate of Marazion is very mild, but is subject to heavy rains. Pop. (1851) 1379.

MARBELLA, a town of Spain, province of Malaga, on the coast of the Mediterranean, 30 miles W.S.W. from the town of Malaga. Few towns on the coast of Spain enjoy a more delightful air or a more charming prospect: from the summit of the Sierra Blanca, behind the town, is seen the mountainous coast of Africa, and to the right rises the rock of Gibraltar; farther on, the town of Estepona, half concealed by wooded hills. The streets are regular, broad, and clean. In the centre stands an ancient Moorish fortress, commonly called the Castillo, within whose inclosure is the cemetery and several religious edifices. There are two public schools and an hospital; the parish church is a large, handsome edifice of modern construction. The schools occupy the ex-convent of San Juan de Dios. On the coast near Marbella are the ruins of the Castle of St Luis, destroyed by the French in 1812. Many of the inhabitants are engaged in fishing; and the sardines taken on this coast are of excellent quality. Marbella rose into importance some years ago upon the discovery of iron in the Sierra Blanca; it is smelted here, and sent on to Malaga to be refined. The principal iron-works are the property of the Heredias of Malaga, and give support to upwards of 130 families, independently of those engaged in the mines. The commerce consists in the importation of oil, wheat, and barley, and in the exportation of sardines and other fish, figs, raisins, and wine, which, though in no great quantity, is of excellent quality. Pop. (1845) 5105. Marbella is the *Sarduba* of Pliny and Pomp. Mela, which, according to Bochart, is its Phœnician equivalent, meaning "City of Salt."

MARBLEHEAD, a seaport-town in the county of Essex, state of Massachusetts, North America, is pleasantly situated on a rocky promontory of the same name, 18 miles N.E. of Boston. The harbour is excellent, being accessible at all times to the largest vessels, and protected from the violence of storms by a breakwater, built in 1845. The inhabitants are chiefly employed in cod-fishing and curing. About 60 boats are employed in the former of these occupations, and about 60,000 cwt. are taken annually, in the curing of which more than 60,000 bushels of salt are used. The principal articles of manufacture are boots, shoes, and cordage. The number of foreign vessels which entered Marblehead harbour during the year ending 30th June 1852 was 168, with a tonnage of 12,129; and the number cleared out was 162, tonnage 11,675. Pop. 6167.

MARBURG, or Mahrburg, a town in Styria, capital of a circle of the same name, is situated on the left bank of the Drave, 36 miles S.S.E. of Gratz. The town is surrounded by walls, and has several suburbs. The principal buildings are,—a castle, a church adorned with several fine pictures, a theatre, gymnasium, military school, and hospital. It has a considerable trade in leather, iron, corn, wine, fruits, &c.; and several annual fairs are held here. The neighbourhood of the town is extremely picturesque, and abounds in vineyards. Marburg is the second town in Styria. Pop. about 5000.

Marburg, a town in Hesse-Cassel, capital of the circle of Upper Hesse, is pleasantly situated on the right bank of the Lahn, 48 miles S.W. of Cassel, and 60 miles N. by E. from Frankfort. The town is not well built, and lies in the form of a semicircle on the slopes of a hill, on which stands a castle formerly the residence of the landgraves of Hesse. Marburg is partly surrounded by walls, and has five gates. The streets are narrow, and in many cases so steep as to be ascended by flights of stairs. The university of Marburg was the first Protestant one established in Germany, being founded by Philip the Generous in 1527. It is attended by about 270 students, has 62 professors and teachers, and a library of about 100,000 volumes. The principal of the other buildings are,—the castle, which in 1529 was the scene of a religious conference between Luther, Melancthon, Zwingle, and others of the Reformers, regarding transubstantiation; and the church of St Elizabeth, a beautiful specimen of the Gothic style, begun in 1235, and completed in 1283, containing the monument and silver coffin of St Elizabeth. Besides this, Marburg possesses two Lutheran and one Calvinist church, a gymnasium, a school of industry, a normal school, a school of surgery, a botanic garden, an hospital, two infirmaries, &c. There are also manufactories of stockings, hats, tobacco, tobacco-pipes, &c. Marburg is the seat of the principal law courts for Upper Hesse. On the other side of the Lahn stands the suburb of Weidenhausen. Pop. of the town, with the suburb of Weidenhausen which stands on the opposite side of the Lahn, 7954.

MARCANTONIO, also known by his family name *Raimondi*, an eminent Italian engraver, is supposed to have been born in Bologna about 1487. After studying painting in that city under Francesco Francia, he repaired to Venice to prosecute his art still further. Seeing, however, exposed to sale some woodcuts of the eminent Flemish artist Albert Dürer, he expended all his money in buying them, and began to imitate them on copper. So faithfully copied was one of these imitations, representing the Life and Passion of our Saviour, that when it had been marked by the initials of Dürer, it is said by Vasari to have been sold throughout all Italy for the work of that eminent engraver. When Albert Dürer, however, heard of this illegal use of his name, he hastened to Venice, and induced the senate to issue a command prohibiting Marcantonio from again employing his signature. Removing soon afterwards to Rome, Marcantonio introduced himself to the notice of Raffaello da Urbino, by a copperplate which he executed of the "Lucretia" of that master. Raffaello accordingly employed him in engraving many of his other designs, including the "Judgment of Paris," the "Slaughter of the Innocents," the "Rape of Helen," and the "Death of Santa Felicita." With so masterly and delicate a hand did Marcantonio execute this undertaking, that his fame spread rapidly, and pupils flocked to him from all quarters. His engravings of the heads of the Cæsars, after ancient medals, wrung a commendation even from the offended Albert Dürer. After the death of Raffaello in 1520, he was employed by Giulio Romano to engrave several of his designs. Among these were twenty plates of figures so grossly indecent, that Pope Clement VII., in a virtuous indignation, threw Marcantonio into prison. There he might have paid an extreme penalty for his crime, had not Cardinal de' Medici and Baccio Bandinelli effectually sued for his release. He then returned to the practice of his art; and by his exquisite engraving of the picture of Baccio Bandinelli, representing the martyrdom of San Lorenzo, he so delighted the pope, that he was forgiven for his former offence and received into favour. More profitable patronage might have been extended, had not the sack and pillage of Rome by the Spaniards followed in 1527. Marcantonio barely escaping with his life, returned a beggar to his native city. He died there not many years afterwards.

Besides being a master in his art, Marcantonio earned the distinction of giving the first stimulus to engraving in Italy. A very full catalogue of his works is given in Heinecken's *Dictionnaire des Artistes*. About 500 of them may be seen in the Print Room of the British Museum. Many of his engravings are anonymous, and some are marked with M.A. or M.A.F. (Vasari is the best authority for his biography. See also Lanzi's *Stor. Pittor.* i.)

MARCELLIN, or Marcelin, *St*, a town of France, capital of a cognominal arrondissement in the department of Isère, is situated at the foot of a beautiful slope near the right bank of the Isère, 21 miles W.S.W. of Grenoble. It is surrounded by walls, and is generally well built. Its chief manufacture is earthenware, and it has some trade in silk and wines. Pop. (1851) 3344.

MARCELLUS, M. CLAUDIUS, the conqueror of Syracuse, was probably born at some period before 268 B.C. He is said by Plutarch to have early shown a valorous spirit and a fondness for single combat. The first public office he is recorded to have filled was that of curule ædile. In 222 B.C. he became consul for the first time. The war with the Cisalpine Gauls was then drawing to a close, and the Insubres had sued ineffectually for peace. Marcellus joined the army without delay, and laid siege to Acerræ (*Gerrha*), on the banks of the Po. When the Gauls attempted to make a diversion by attacking Clastidium, he left his colleague before Acerræ, and having reached them by forced marches, defeated them, and slew their general, or king, Viridomarus, with his own hand. This was the third time that a Roman general had presented the *spolia opima* to Jupiter Feretrius. Marcellus obtained the honours of a triumph, which is said to have been one of the most magnificent ever witnessed in Rome. At the commencement of the second Punic war (B.C. 218), Marcellus was appointed as prætor to the command of the troops in Sicily; but he was recalled after the defeat at Cannæ (2d August B.C. 216), and sent to Apulia to collect the remains of the shattered Roman army. This he effected with much prudence; and the severe check which Hannibal received from him before Nola, tended greatly to reanimate the drooping spirits of his countrymen. Hannibal used to say, that he feared Fabius as his schoolmaster, and Marcellus as his enemy. Marcellus was again named consul, B.C. 215; but owing to the unfavourable prognostications of the augurs he immediately abdicated, and proceeded to Nola as proconsul. In the following year he was raised a third time to the consulship, and proceeded to the command of the war in Sicily. There he began to storm Syracuse by sea and land; but his powerful engines were baffled at every point by the more powerful contrivances of Archimedes; and not till after a blockade, of three years was the city taken. In the lawless pillaging that ensued, Marcellus attempted in vain to save the life of Archimedes. That philosopher was slain when absorbed in his mathematical studies. During the blockade, Marcellus, at the head of part of his army, had been waging a desultory warfare with the Carthaginians in Sicily; yet, with the exception of a few towns, that island remained unsubdued. Accordingly, on his return to Rome, Marcellus was only honoured with an ovation or lesser triumph. He brought from Syracuse many beautiful statues and paintings, and was the first who taught the Romans to appreciate the exquisite works of Greece, hitherto unknown to them. He was named for the fourth time consul, B.C. 210, and the command of the war in Sicily fell to him by lot; but he exchanged it for Italy with his colleague Lævinus. Marcellus recovered several cities of the Samnites from Hannibal, who carefully shunned any regular battle with his opponent. In the following year he retained the command of his army as proconsul. He was appointed consul the fifth time, B.C. 208, when he fell into an ambush which had been laid for him by Hannibal, and was killed. Thus fell Marcellus, who was called the *sword* of Rome, in contrast with Fabius, who was entitled its *buckler*. Plutarch and Livy, the chief authorities for the life of Marcellus, represent him as having gained many victories over Hannibal. Yet Polybius (xv. 2) denies that he ever defeated the great Carthaginian at all, a testimony that certainly countenances the opinion that Marcellus is generally overrated. In fact, he seems to have been brave, daring, and hot-headed; with much of the obstinate harshness of an illiterate soldier, and with little of the far-seeing prudence of a great general.

MARCELLUS, *M. Claudius*, of the same family as the conqueror of Syracuse, first appears in history as curule ædile, along with P. Clodius, in 56 B.C. He was named consul (B.C. 51), along with Sulpicius Rufus; and he proposed that Cæsar should be deprived of the command of the armies of Gaul; but this advice was not followed. (Cic. *Att.* vii. 1.) The civil war broke out (B.C. 49), and Marcellus joined the party of Pompey; but on the death of the latter (B.C. 48), he ceased to take part in the political affairs of his country, and retired to Mitylene, that he might not witness the overthrow of the republic. Here he was found by Brutus as he was returning from Asia. (Senec. *ad Helv.* c. 9.) His friends at Rome, however, were anxious that he should return, and they did not find it difficult to prevail on Cæsar to forget the part he had taken against him. His pardon, indeed, was more readily granted by Cæsar than accepted by Marcellus. If we may judge from the letters addressed to him by Cicero, and now known as the seventh, eighth, ninth, and tenth of the fourth book of *Epistolæ ad Familiares*, Marcellus was unwilling to leave his retreat at Mitylene. He, however, yielded, and had reached Athens on his way homewards, when one of his companions in exile, P. Magius Chilo, actuated by private resentment, murdered him, B.C. 46. His old colleague, Sulpicius, happened to be at Athens at this time, and superintended the celebration of his funeral rites. (Cic. *ad Div.* iv. 12.) Marcellus is the subject of the eloquent speech *Pro M. Marcello*, often erroneously ascribed to Cicero.

MARCELLUS, *M. Claudius*, son of C. Marcellus and of Octavia, the sister of Augustus, was born about 43 B.C. He was educated by his mother with the utmost care, and gave early indications of all those qualities that unite in forming a great and good character. In 39 B.C. he was betrothed to Pompeia, the daughter of Sextus Pompey, then a girl of six years of age. (Dion Cass. xlviii. 38.) Released, however, from this engagement by the death of Pompey in 35 B.C., he married Julia, the daughter of Augustus, in 25 B.C., and at the same time became the adopted son of his father-in-law. (Dion Cass. liii. 27; Suet. Aug. 63.) Marcellus was also admitted into the senate, and received the privilege of sueing for the consulship ten years before the legal period. He became curule ædile in 23 B.C., but he died in the autumn of the same year, owing, it is said, to the imprudent use of a cold bath, prescribed by Antonius Musa, the celebrated physician of Augustus. (Dion Cass. liii. 30.) Fond of study, gentle in his disposition, and temperate in his habits, Marcellus was the idol of his countrymen, and his death was mourned as a public calamity. As it had been generally understood that Augustus intended him for his successor, a rumour became current that the Empress Livia had poisoned him, to secure the succession to her own son, Tiberius. The death of Marcellus was the cause of the most intense sorrow to his mother, Octavia, and to Augustus. The latter interred him, with the greatest pomp, in the Julian mausoleum, pronounced his funeral oration, and afterwards dedicated to his memory the magnificent theatre known as the *Theatrum Marcelli.* (Tacit. *Ann.* iii. 64.) But Marcellus is now best remembered by the touching description of him in the Æneid, which is said to have affected his mother even to fainting:—

> Heu ! miserande puer, si quid fata aspera rumpas,
> Tu Marcellus eris.

MARCH, the third month of our modern year, containing thirty-one days. As in the Roman year, so in the English ecclesiastical calendar, used till 1752, this was the first month, and the legal year commenced on the 25th of

March. The Romans called this month *Martius*, from the god Mars, the reputed father of their nation; and it received the name *Hlyd Monath, i.e.*, loud or stormy month, from the Anglo-Saxons. There is an old saying, common to both England and Scotland, which represents March as borrowing three days from April; which are thence called the *Borrowing* or the *Borrowed days.* In the "Complaynt of Scotland," we find "the borial blastis of the *thre borouing dais of Marche* hed chaisset the fragrant flureise of evyrie frut-tree far athourt the feildis." And these *borouing dais* are described in the glossary as "the three last days of March" to which the following popular rhyme refers:—

> "March borrowit from Averill
> Three days, and they were ill;"

and then there is another rhyme, which graphically characterizes those three "ill" days in detail,—

> "The first, it sall be wind and weet,
> The next, it sall be snaw and sleet;
> The third, it sall be sic a freeze,
> Sall gar the birds stick to the trees."

Dr Jamieson, in his *Etymological Dictionary of the Scottish Language*, says, "These days being generally stormy, our forefathers have endeavoured to account for this circumstance, by pretending that March *borrowed* them from April, that he might extend his power so much longer. . . . . . Those who are much addicted to superstition will neither borrow nor lend on any of these days."

MARCH, a market-town in the Isle of Ely, Cambridgeshire, England, is situated on both sides of the Old Nene, 13 miles N.W. of Ely, and 32 miles N. by W. of Cambridge. The town consists of two main but narrow streets, and the houses are low and ill-built. The church is a fine old building of the fourteenth century, and there are also Baptist and Independent places of worship, and national schools. The River Nene, which is here crossed by a bridge, is navigable to the town, and affords it the means of carrying on a considerable trade in corn, hemp, flax, coal, timber, &c. Market-day, Friday. Pop. (1851) 4171.

March, *Morawa*, or *Morava*, a river in the Austrian dominions, giving its name to Moravia, rises on the confines of Bohemia and Glatz. It flows in a southerly direction through Moravia, and receives many considerable streams, such as the Hanna, Taya, Zaya, and Rust, on the right, and the Beczwa, Miava, and Bodawa, on the left. It then forms the boundary between Hungary and Austria, and falls into the Danube above Presburg. The principal towns on its banks are,—Olmutz, Kremsir, and Hradisch. It is navigable for about 50 miles to Goding on the boundary of Moravia. Total length, 180 miles.

MARCHAND, Prosper, a learned bibliographer, born in 1675, at Guise, in Picardy, studied at Paris with much success, and having from his infancy been passionately devoted to books, he was admitted in 1698 into the corporation of booksellers. An eager collector of literary anecdotes, he transmitted them to Jacques Bernard, who then conducted in Holland the *Nouvelles de la République des Letters.* In 1711 Marchand passed into Holland, that he might be more free to profess the Reformed religion, which he had embraced. He established himself at Amsterdam, and there continued for some time the business of bookselling, but ultimately abandoned it altogether, in order to devote himself exclusively to study. He died on the 14th of June 1756, and left his rich library to the University of Leyden. In addition to his extensive annotations, &c., Marchand's principal works are,—*Histoire de l'Origine et des premiers Progrès de l'Imprimerie*, Hague, 1740, in 4to; *Dictionnaire Historique*, or Critical and Literary Memoirs of different distinguished persons, particularly in the republic of letters, Hague, 1758, 1759, two volumes folio.

MARCHE, an old province of Central France, bounded on the N. by Berri, N.E. by Bourbonnais, E. by Auvergne, S. by Limousin, S.W. by Guyenne, and W. by Angoumois and Poitou. It now forms the greater part of the department of Creuse, and parts of those of Haute-Vienne, Charente, and Indre.

MARCHENA, a town of Spain, in the province of Seville, situated in a sandy valley and on two small hills, 30 miles E.S.E. of Seville, was formerly surrounded with walls and towers, of which some remains are still to be seen. The town contains about 1584 houses, generally of two storeys, and the streets are narrow and tortuous. The most remarkable buildings are the palace of the dukes of Arcos, formerly lords of the town, within the inclosure of which is the ancient church of St Mary de la Mota, the tower of which is of some architectural merit; and the church of St John, the present structure dating from 1490. At the eastern extremity of the town is a sulphureous spring resorted to for the cure of cutaneous diseases. The soil of the surrounding district is partly clayey and partly sandy; a seventh part of it is wood or pasture; the rest is under cultivation. The productions are wheat, barley, beans, peas, vetches, olives, oil, grapes, and wine. The wheat, barley, oil, and wine are exported to Seville, some oil even to Malaga. Horned cattle and sheep are reared, as also mules and horses; the River Corbones furnishes fish. Ordinary linen and coarse woollens are manufactured. There are also potteries of common earthenware. A cattle-market is held the first three days of September. Pop. (1845) 11,620.

MARCION, the founder of the sect of the *Marcionites*, is generally held to have been the son of the Bishop of Sinope, and to have been born in that city about the beginning of the second century. He is said by Tertullian to have been a shipmaster, and Rhodon calls him a seaman. Possessed of an earnest and independent mind, he probably arrived at a belief in Christianity without any human aid, an opinion that is supported by the reference which he makes to "the first glow of his faith." After thus receiving the Scriptures, Marcion proceeded in the same bold yet sincere spirit to interpret them. Startled by the seeming dissimilarity between God as manifested in Christ, and God as revealed in nature, he jumped at once to the conclusion that they are two distinct and irreconcileable beings, the one good and loving, the other inexorable and cruel. This doctrine once adopted, he immediately reduced to practice, by neglecting the body as the work of the latter, and by stringently obeying the gospel as the sole emanation from the former, by becoming a severe ascetic, and by presenting a great part of his estate to the church. As he proceeded in his speculations he saw the same contrariety between the Jehovah of the Old Testament, whose characteristic appeared to be jealousy, and the God of the New Testament, whose essence is love. A like antagonism he seemed to discover between the Messiah of the Jews, the destined heir of a large worldly kingdom, and Jesus, the poverty-stricken man of sorrow. Thus he was gradually led to reject the Old Testament as directly contradictory to the New, and as intended for the Jews only, and not for the whole of mankind. This heresy was very probably the cause of his excommunication from the church at Sinope. Marcion then repaired to Rome, in the hope that his new doctrine would awaken some sympathy in the church of that city, but there also he was rejected as a heretic. Discountenanced so severely by all professing Christians, he now began to consider himself the sole representative of primitive Christianity. Accordingly, he set himself to arrange his opinions into a system that might be received into the minds of men, and in this task he was assisted by a Gnostic teacher named Cerdo. He displayed remarkable zeal in making converts to his opinions, and with apostolic spirit he journeyed frequently abroad, glorying to

Marcion.

endure privation, malice, and contempt, and loving to address his proselytes as "fellow-sufferers of hate and hardship." Yet Marcion still cherished a sympathy and respect for many of his former friends, a circumstance that may have partly originated the prevalent opinion that he desired in his latter years to be re-admitted into the church. He is said by Irenæus to have met the venerable Polycarp at Rome, and to have asked him if he remembered him. "Yes," was the reply, "I remember thee, the first-born of Satan." The date of Marcion's death is unknown.

The following is an outline of the creed of the Marcionites in its later and more developed form. They assumed that there were three original principles:—(1.) The good, perfect, and holy God; (2.) the evil Matter; and, (3.) the Demiurge, a being of finite power and imperfect goodness, who is sometimes, but improperly, styled God. Between the two last principles there is a natural and never-ending conflict for the mastery. It began by the Demiurge laying hold upon a part of matter and forming out of it the world and all its inhabitants. Into the human creature—his masterpiece—he infused a soul, moulded out of his own essence, after his own image, and bounded his conduct by a law which he might not transgress on pain of punishment. But man, thus formed of two antagonistic elements, was tossed to and fro by their conflicting influences, until he was driven beyond the boundary which his Maker had set up, and was consigned to the dominion of matter, and the evil which it necessarily entails. The Demiurge then selected the Jews to be his representatives on the earth, gave them a ceremonial and a moral law, promised happiness as a reward of their obedience, and threatened perdition as a punishment of their disobedience. He also foretold a Messiah, who should conduct the Jews to the height of earthly felicity, and spurn the heathen into the depth of misery and ruin. At this crisis the good God, who had hitherto sat remote in a holy inactivity, interfered to thwart the unjust designs of the Demiurge. Deeming it cruel that men should be punished for an imperfection that is innate, and therefore insurmountable, he sent into the world his son, Christ (a man in semblance, but not in reality), with an offer of divine life and blessedness to all who should merely trust in him. This message of love, so directly opposed to the message of justice that had hitherto been proclaimed, incited the Demiurge to crucify the Divine Messenger, and to attempt to bind him in hell. To this apparent defeat the Son of God submitted, for no other purpose than to free the souls of the dead who were held under punishment by the Demiurge. Accordingly, he clad himself in his native omnipotence, released all the Gentiles in the place of torment, ascended in triumph along with them to his Father's heaven, and thus crushed and confounded the tyranny of his enemy. Thither all who believe in his name will follow, but all who reject his gospel will be left to the judgment of the Demiurge.

From this system of doctrine there necessarily arose a system of morals different in many respects from those of other Gnostics. The Marcionites held that, in purifying the heart and regulating the conduct, the *law* was powerless, but the *gospel* effective. They gloried in suffering martyrdom, and they refused to baptise all those who would not resist the power of matter by leading a life of asceticism, and refraining from marriage.

Marcion considered St Paul the only genuine teacher of Christianity. Accordingly, he rejected all the books of the New Testament except the works of that apostle. He acknowledged also a pretended original gospel, which was nothing else than a mutilated copy of St Luke. Marcion wrote a work entitled *Antithesis*, in which he quoted the apparent contradictions between the Old and the New Testament. (See Neander's *Church History*, vol. ii., p. 129. Bohn, 1850.)

Marcomanni || Mardin.

MARCOMANNI, a powerful confederacy of ancient Germans, who were resident, as their name imports, on the borders. They are first mentioned in history by Cæsar, and seem at that time to have dwelt upon the banks of the Rhine. From Tacitus, Paterculus, and Strabo, we learn that they soon afterwards moved westward, under their king Maroboduus, drove the Boii out of Bohemia, and settled in that country. After organizing a government, Maroboduus formed a league with the neighbouring tribes, for the purpose of defending Germany against the Romans. He was thus enabled to muster 70,000 disciplined soldiers, and to conclude an honourable treaty with the Emperor Tiberius, A.D. 6. Yet he was defeated by the Cherusci and their allies A.D. 17; and in two years afterwards he was expelled from his throne by the Goth Catualda, and forced to seek a refuge in Italy. The same fate soon afterwards befell his dethroner and successor, and the Marcomanni once more came under the sway of native kings. After this they gradually extended their dominions, until they had reached the Danube, and had provoked the jealousy of the Romans in the time of Domitian. Then began those hostilities between the Romans and the Marcomanni, which, after being checked by Trajan and Hadrian, and resumed with fresh animosity in the reign of M. Aurelius, issued, in 166, in the protracted struggle of the Marcomannic war, and were finally quelled by the peace of Commodus, in 180. Favoured, however, by the feeble rule of this last emperor, the Marcomanni continued their predatory inroads into the Roman provinces of Noricum and Rhætia, and ventured sometimes as far as the defiles of the Alps. In 270, in the reign of Aurelian, they pushed forward into Italy, and penetrated even to Ancona, spreading consternation around them. After this period they disappear gradually from history, and are mentioned for the last time among the hordes of Attila.

MARCOUF, or MARCOU, ST, two small islets lying in the English Channel, off the coast of Manche in France, about 4 miles from the mainland, and 12 miles N.E. of Carentan. They are mere barren rocks, but in a military point of view are of considerable importance as defences for the roadsteads of Havre and Cherbourg. The navigation is here very dangerous, and they cannot be approached without a pilot. They were taken by the British in 1795, but restored to France at the Peace of Amiens.

MARCUS, THE HERESIARCH, a Gnostic philosopher, lived in the second century. From his frequently employing forms from the Aramæan liturgy, Neander infers that he was born in Palestine. Yet Jerome holds that he was an Egyptian, a supposition confirmed in a great measure by the fact that he was a disciple of Valentine. According to Irenæus and other fathers, he was systematically addicted to licentiousness. Concerning his life nothing further is known. "Marcus set forth his system in a poem, in which he introduced the divine Æons discoursing in liturgical forms, and with gorgeous symbols of worship. After the fashion of the Jewish Cabala, he discovered special mysteries in the numbers and positions of letters. The idea of a λόγος τοῦ ὄντος, of a word manifesting the hidden divine essence in the creation, was spread out by him into the most subtle details; the entire creation being, in his view, a continuous *utterance* of the ineffable." (Neander's *Church Hist.*, sect. iv.) The followers of Marcus were called *Marcosians.*

MARDIN, a town of Asiatic Turkey, in the pashalik of Diarbekir, on a bold limestone crag of Mount Masius, about 2300 feet above the sea, 57 miles S.E. of Diarbekir, and 335 N.W. of Baghdad. The summit of the rock is occupied by the castle, and the town is built on the southern and eastern sides. The streets consist of terraces, running along the hill, and are joined to each other by flights of steps. The houses are built of stone, and are in general small, with flat roofs. The town possesses eight mosques, with some bazaars and public baths. The castle is now in ruins, but commands a magnificent view over a large extent of rich and well cultivated land. Linen and cotton fabrics are manufactured here, and a considerable trade is carried on in these and other articles. The population is estimated at about 20,000, two-thirds of whom are Mohammedans, and the remainder Christians with a few Jews.

MAREE, Loch, a lake in the parish of Gairloch, Ross-shire, Scotland, near the W. coast, is situated in a mountainous and little frequented district. It is about 20 miles in length, and has an average breadth of 1½ miles. It is fed by many mountain streams, and discharges its waters by the Ewe into an arm of the sea called Loch Ewe, which lies to the N.W. The scenery of the loch is of the wildest and most sublime description, the mountain summits which surround it rising in some places to the height of 3000 feet
5000 above the sea. Near the centre of the loch there is a group of islands, about twenty-seven in number. The largest of these is called Ealan Sovin, or St Swithin's Isle, and has an area of about thirty acres.

MAREMMA, La, or Maremme, the name given by the Italians to the marshy regions which stretch along the coast of the Mediterranean, but more particularly applied to those in Tuscany and the States of the Church. This tract of country is extremely unhealthy, especially from midsummer to the autumnal equinox, when it is exceedingly dangerous, and often fatal, to spend a single night in the Maremma; so that the country which was anciently the seat of the most flourishing Etruscan cities, is now almost entirely deserted. The Maremma is divided into several basins by mountain ridges which stretch from the Apennines to the coast. The first basin extends from Lucca to the ridge of Montenero, S. of Leghorn, and stretches about 10 or 12 miles inland. The second basin is smaller in extent than the first, and extends to a few miles S. of the Cecina, where the mountains again approach the sea. This part is called the basin of Cecina. The third basin stretches into the Papal territory, and is bounded on the S. by Mount Cimino, which divides it from the basin of the Tiber. The fourth basin, that of the Lower Tiber, extends as far as the Alban Mount, which separates it from the fifth, that of the Pontine Marshes. Similar plains stretch into the kingdom of Naples, but they are known by the name of Paduli. The Tuscan government have made considerable improvements in the northern part of the Maremma by means of drains and embankments, and parts of the ground have been brought into cultivation.

MARENGO, a village in the Sardinian States, Italy, is situated in a large plain near the Bormida, 3 miles E. by S. of Alessandria, of which it is sometimes regarded as a suburb. It is remarkable for the victory gained here, 14th June 1800, by the French under Napoleon, over the Austrians under Melas, by which the former became masters of all the north of Italy.

MARENNES, a town of France, capital of a cognominal arrondissement, in the department of Charente-Inferieure, is situated near the mouth of the Seudre, about a mile from the Bay of Biscay, and 24 miles S. of La Rochelle. Marennes is a well-built and thriving commercial town, with tribunals of primary instance and of commerce. It is surrounded by salt marshes, which render it very unhealthy, but constitute a great source of profit to the town from the salt that is got from them. The principal articles of commerce are salt, oysters, brandy, and agricultural produce. Pop. (1851) 4534.

MARGARET, Queen of Denmark, Norway, and Sweden, called the *Semiramis of the North*, was the daughter of Waldemar III., King of Denmark, was born at Copenhagen in 1353, was married to Haquin, King of Norway, in 1363, succeeded her husband on the throne of Norway in 1380, and her son on the throne of Denmark in 1387, wrested the crown of Sweden from Albert in 1397, and died in 1412. See Denmark, Norway, and Sweden.

Margaret *of Anjou*, daughter of René, titular king of Sicily, was born in 1425, was married to Henry VI. of England in 1443, and died in 1482. See England.

Margaret *of France*, daughter of the French king Henri II., was born in 1552, was married in 1572 to the Prince of Béarn, afterwards Henri IV. of France, and died in 1615. See France.

MARGARITA, an island in the Caribbean Sea, lies off the coast of Venezuela, of which republic it forms a province, 30 miles N. of Cumana; Lat. 11. 30. N., Long. 64. W. It is about 45 miles in length, and varies in breadth from 5 to 20 miles. Area 441 square miles. It is separated from the mainland by a channel 20 miles in breadth, which has to be passed through by all vessels approaching from the E. the ports of Venezuela. The island is composed of two parts, united by a low and narrow isthmus, so that from a distance it presents the appearance of two distinct islands. At the isthmus the land is not more than 10 or 12 feet above the level of the sea, but near the western extremity a lofty mountain, called Maranao, rises to the height of 3000 feet. Near the sea the soil is dry and unproductive, and the coasts are rugged and bold, indented, however, with three harbours, Pampatar on the S.E., Pueblo-de-la-Mar on the S., and Pueblo-del-Norte on the N. In the interior, the soil, though sandy, is fertile, and produces Indian corn, bananas, sugar, cotton, &c. Live stock and poultry are also reared; and salt and fish are obtained in considerable quantities. The island derives its name from the pearls found here, the fishing of which formed a considerable part of the occupations of the inhabitants. This was principally carried on in the rocky islet of Coche, in the channel of Margarita; but this branch of industry has much declined of late, as the pearls are now neither so large in size nor so fine in quality as formerly. The principal manufactures of the island are those of cotton stockings and hammocks. A good deal of illicit traffic goes on between this island and the British and French possessions in the West Indies. Margarita is more thickly inhabited than any other part of South America; and there are several towns and villages in the island, the most important of which are, Assumpcion, the capital, which is a well-built town, not far from the centre, and Pampatar, a seaport on the S.E. This island was first visited by Columbus in 1498, and has in more recent times (1816) been the scene of a bloody warfare betwen the revolutionists and the Spanish troops under General Murillo, in which the latter were defeated. Pop. (1854), 23,967.

MARGARITONE, D'Arezzo, an Italian painter, sculptor, and architect of great reputation, was born at Arezzo in 1212. He belonged to the Greek school of art, and executed many pictures at his native place in tempera and in fresco. The most celebrated specimens of the latter style of painting executed by Margaritone were to be found in the church of San Clemente, afterwards destroyed by Duke Cosmo de' Medici when rebuilding the old walls of Arezzo. There still remain in Arezzo, however, a few specimens of the frescoes of this artist of great value. One of the most characteristic and important of these pictures was a work executed for the nuns of Santa Margarita, believed by some to be still recognisable among the Florentine pictures collected by the Signors F. Lombardi and Ugo Baldi. But of the "endless number of pictures," as Vasari phrases it, which Margaritone executed for his native city, the one on which the artist himself set the highest value, and "on which he placed his name," was a "San Francesco," painted for the convent of the Friars de' Zoccoli at Sargiano, a work which still exists with his own inscription of "*Margarit. de Aretio pingebat.*" He had a peculiar contrivance to prevent clefts and fissures in wood paintings. That the joinings might not appear after the painting had been completed, he covered the whole surface of the wood with canvas, secured with strong glue made from shreds of parchment, and next applied a layer of gypsum and glue to the outer surface of the canvas.

It is said that Margaritone succeeded better in sculpture than in painting. He improved upon his first efforts, which were executed in the Greek style, on coming in contact with the works of Arnolfo and other distinguished sculptors of Florence. Appointed to construct a tomb at Arezzo for Gregory X., who had died there, he executed a reclining statue in marble of that pontiff, still in good preservation, and a painting of his holiness, now entirely effaced. This masterpiece of art was considered "the best work he had yet produced." On the death of Maestro Lapo, who planned the episcopal buildings of Arezzo, Margaritone superintended the erection of the cathedral after the design of the original architect. A war between Arezzo and Florence in 1289 prevented the completion of this magnificent undertaking. Vasari is of opinion that it was this architect who planned the Governors' palace in the city of Ancona in 1270, and who executed the sculptured ornaments of the front windows of that beautiful edifice. He died at Arezzo in 1289, aged seventy-seven. (Lanzi, *Stor. Pitt.*)

MARGATE, a seaport, market-town, and watering-place of England, in the Isle of Thanet, county of Kent, is situated along the shore and on the slope of two hills, 3 miles W.N.W. of the N. Foreland, 15 miles N.E. by E. of Canterbury, and 72 E. by S. of London. The name of the town is believed to be derived from *Meregate*, a gate or opening to the sea; on account of the hollow between the two hills on which the town is built. Margate was till recently only a small village, and the older parts of the town which lie along the shore are irregularly and meanly built; but the upper part, which is more modern, contains several fine streets and squares, is well built and paved. It is principally noted as a fashionable watering-place, and is still very much frequented in the summer season, although the construction of railways to the seaports on the S. coast has somewhat diminished the number of its visitors. The parish church of St John is an ancient edifice, in the Gothic style; a modern church in the old English style, with a lofty tower, was built in 1825. There are also places of worship for Methodists, Presbyterians, Independents, Baptists, the Countess of Huntingdon's Connection, Society of Friends, and Roman Catholics. The assembly rooms of Margate are reckoned among the handsomest and largest buildings of the kind in England, and are adorned with a colonnade of Doric pillars. The town has also a fine theatre, as wall as baths, libraries, and other establishments for the convenience of visitors. The town-hall is of recent construction, and is supported on iron pillars, and fronted with a handsome portico. The harbour of Margate is dry at low water; and in order to obviate this defect, a stone pier, 900 feet in length, with a lighthouse at the end, was constructed at a cost of L.100,000. But this proving insufficient, a wooden jetty was also built, 1100 feet long, at which steamers can touch in all states of the tide, except when the weather is very stormy. The pier, the marine terrace, and the esplanade, form the most fashionable and most frequented promenades of Margate. The walks in the vicinity are numerous, and the scenery is very beautiful. Fishing is still carried on to a considerable extent here; and there is some trade with the Netherlands; but the prosperity of the town depends chiefly on the summer visitors. Margate communicates with London by a branch of the South-Eastern Railway, and steamers also ply by sea, performing the journey in six or seven hours. The market-days are Wednesday and Saturday. Pop. (1851) 9107.

MARGHILAN, or MARGINAN, a town of Independent Turkestan, is situated in a fertile plain, 25 miles S.E. of Khokhan. It is large and well built, surrounded by earthen ramparts, and containing a lofty and ancient tower, a caravanserai, and several mosques. Manufactures are carried on here of gold and silver articles, as well as silk and velvet, and the trade is considerable with Bokhara and Cashgar.

MARGRAVE. See LANDGRAVE.

MARIA ISLAND is situated between 2 and 3 miles from the E. coast of Van Diemen's Land, in Lat. 42. 40. S., Long. 148. 10. E. It is about 12 miles in length from N. to S., by 7 in extreme breadth. It consists of two parts, connected by a low and narrow neck of sand, almost covered at high water, but it rises at either extremity into mountains. On each side of the isthmus there is a large bay,—that on the W. being called Oyster Bay, and that on the E. Reidle Bay. The shores of the island abound in seals and zoophytes, and immense quantities of sea-weeds, growing up from a depth of 250 or 300 feet, impede navigation. The geological structure of Maria Island is principally of trap; but on the E. coast perpendicular cliffs of granite rise to the height of 300 or 400 feet from the sea; and as they are pierced by many large caverns, the sea rolls in with a noise resembling thunder. On the other side of the island the land slopes gradually down to the sea-level. The soil of the interior is rich and productive, and the scenery extremely picturesque. On the northern extremity is situated the valley of Darlington. This island was discovered by Tasman in 1642.

MARIA THERESA, daughter of Charles VI. of Austria, Queen of Hungary and Bohemia, and Empress of Germany, was born at Vienna on the 13th of May 1717. By the Pragmatical Sanction of 1724 her father had regulated the succession in the family of Austria, and failing of male issue his daughter Maria was declared heiress of the Austrian monarchy; a settlement which was guaranteed by the principal states of Europe. In 1736 Maria Theresa married Francis-Stephen of Lorraine, afterwards Grand Duke of Tuscany, and on the 20th October, 1740, on the death of her father the Emperor Charles VI., she succeeded to the throne of Hungary and Bohemia, and the other hereditary states of her house, her husband being declared co-regent. No sooner had she ascended the throne than she was assailed by the kings of Prussia, France, Spain, Sardinia, and the electors of Bavaria and Saxony, who conspired to dismember the Austrian dominions and seize upon the portion of her territory to which each of those powers asserted a claim. Frederick of Prussia demanded Silesia, and on meeting with the indignant refusal of the brave young empress, marched his troops into that province. Charles Albert of Bavaria, assisted by the French, moved direct upon Vienna, and compelled Maria Theresa to quit her capital. At this juncture the aspect of her affairs was depressing in the extreme. Her kingdom exhausted, her people discontented, an empty treasury, and an army reduced to 30,000 men, with all her neighbours up in arms against her, and with a husband weak in intellect and destitute of energy,—this spirited empress of twenty-three turned resolutely upon her foes, appealed to the chivalrous enthusiasm of her brave Hungarians, and bade defiance alike to Frederick of Prussia and her kinsman of Bavaria. On quitting her capital, she repaired to Presburg, and summoning the diet of Hungary, she appeared in the midst of the assembly with her infant son in her arms. She addressed them in Latin with great eloquence, and on exclaiming, "Forsaken by all, we seek shelter only in the fidelity, the arms, the hereditary valour, of the renowned Hungarian nobility," that martial assembly shouted, as their swords leapt from their scabbards, "Let us die for our *king* Maria Theresa." (*Moriamur pro Rege nostro Mariâ Theresâ.*) The Hungarian nobles mounted horse, brought their whole military force into the field, and, in conjunction with the gallant troops of General Kevenhuller and Prince Charles of Lorraine, succeeded in driving the French and Bavarians beyond the dominions of their sovereign. Her numerous enemies were gradually silenced, and the current of invasion no longer set against her. She was constrained, however, to come to terms with Frederick of Prussia, by ceding to him Silesia; but she made a treaty of alliance with Sardinia against France and Spain; and the elector of Saxony, who had also made peace with her, subsequently rendered her material service when her old enemy of Prussia found fresh cause for invading the Austrian dominions. On the death, in 1746, of Charles Albert, who had been elected Emperor of Germany by the Frankfort diet, Maria Theresa's husband, the Grand Duke Francis, was raised to the imperial throne. Meanwhile the Austrian and Piedmontese troops were attended by signal success in Italy; they overthrew the French and Spaniards at Piacenza, and gained a temporary possession of Genoa, when after much hard fighting in Italy and Flanders, the peace of Aix-la-Chapelle, in 1748, closed the war of the Austrian succession, and left Maria Theresa in possession of all her territories except Silesia. Deeply mortified by the loss of the latter province, the indefatigable empress joined France and Russia, and embarked with fresh energy in the Seven Years' War against Frederick of Prussia, in the hope of recovering that portion of her territories which the war of the succession had taken away. But 1763 saw the termination of this contest, and left the great Prussian still in possession of the province of his Austrian neighbour. Maria Theresa lost her husband in 1765, and her son Joseph was immediately elected emperor. Yet this vigorous woman continued to retain the administration of her extensive possessions during her life, and showed much solicitude for the welfare of her people, and marked enlightenment in the measures proposed for their improvement. Although a sincere Roman Catholic, she nevertheless employed a firm hand in drawing the line of demarcation between temporal and spiritual jurisdiction. She checked the arbitrary power of the Inquisition, and the ultimate abolition of that obnoxious institution in Lombardy and Tuscany, under her sons Joseph and Leopold, was only the legitimate development of the system of reform conceived and set on foot by their imperial parent. She reformed various abuses in the church, repressed the Jesuits, abolished the torture, encouraged the arts, advanced agriculture, and instituted universities and schools of which many still bear her name. The great stain in the political character of Maria Theresa is the part which she took in the partition of Poland. Yet it is said she left a written record of her sense of the injustice of this act, and of the manner in which she was induced to consent to the measure. She at first refused acceding to the treaty of partition framed by Russia and Prussia in 1772, but being afterwards informed that the dismemberment of Poland would be effected without her consent, and that her own possessions would be thereby imperilled, she, in compliance with the urgent importunities of Prince Kaunitz and her son the Emperor Joseph, agreed to take part in the foul wrong about to be inflicted on that unhappy country. Irreproachable in her private character, she gave a tone and elevation to the morals of her court, by which it stood out in bright contrast to the profligate courts which disgraced the contemporary sovereigns of Europe. In short, Maria Theresa ranks unmistakeably among those sovereigns whom mankind remember with admiration, and she will ever occupy an honourable place amid the select band of the world's illustrious women. She died at Vienna on the 29th November 1780, leaving a family of five sons and ten daughters to mourn her loss. With Maria Theresa ended the dynasty of Hapsburg. (See AUSTRIA.)

MARIANA, JOHN, a celebrated Spanish historian, born in 1537, at Talavera, in the diocese of Toledo. He studied with distinction at the university of Alcala, and was admitted, at the age of seventeen, into the Society of Jesus, where he soon attracted notice by the vivacity of his disposition and the extent of his acquirements. Called to Rome in 1561, he there professed theology during four years, and reckoned among his pupils young Bellarmin, afterwards the celebrated cardinal. He then passed into Sicily, where he remained two years. In 1569 his superiors sent him to Paris, and he there explained the doctrines of St Thomas, in presence of a great concourse of auditors attracted thither by his reputation. But the decline of his health, occasioned by vigils and fatigues, having forced him to renounce teaching, he, in 1574, obtained permission to return to Spain. He retired to the house of the Jesuits at Toledo, and there he composed the works which, in adding to his celebrity, disturbed the peace of his life. Mariana displayed too much liberality and candour for his age. If he censured regal vices in his work *De Rege*, he was accused of treason; and if in *Del Gobierno de la Compañia* he pointed out the defects of his order, he excited the bitterest animosity of the Jesuits, and had his books burnt for his pains. He bore with patience, however, the criticisms and persecutions to which he was exposed, and died on the 17th of February 1624, at the age of eighty-seven.

The great work of Mariana is entitled *Historiæ de Rebus Hispaniæ, libri* XXX. *cum Appendice.* The first twenty books of this history, which terminates at the year 1428, were printed at Toledo, in 1592, folio, and the five following books in 1595. The success of this work induced the author himself to translate it into Spanish; and he at the same time made considerable changes in and additions thereto. The most esteemed Latin edition is that of the *Hague*, 1733, in two volumes folio, with the continuation of Jose Emmanuel Miniana from 1516, where Mariana stopped, to the year 1609. Amongst the Spanish editions the most beautiful of all is that of Valentia, 1783–1796, in 9 vols., accompanied with chronological tables, and enriched with critical notes and observations. The history of Spain by Mariana is esteemed for the extent of the author's researches, the general exactness of his facts, the sagacity of his reflections, and, above all, for the merit of his style, in which, in simplicity and elegance, he makes a nearer approach to Livy than do the most of modern historians. Mariana, however, has been reproached with neglecting to cite his authorities, and sometimes drawing on his imagination to supply defects in historical documents; and he has also committed some errors, which were exposed with much bitterness by Father Mantuano, secretary to the Constable of Castille, in his *Advertencias a la Historia de J. de Mariana*, Milan, 1611, in 4to, a work which Tamaio de Vargas endeavoured to refute.

The other works of Mariana are,—*De Rege et Regis Institutione libri tres*, Toledo, 1599, in 4to; the original edition of a work famous in its day, and now much sought after by the curious; *Liber de Ponderibus et Mensuris*, Toledo, 1599, in 4to; *Tractatus Septem, Theologici et Historici*, Cologne, 1609, in folio; *Scholia brevia in Vetus et Novum Testamentum*, Madrid, 1619, in folio, a work commended by Simon, who pronounces Mariana one of the most able and judicious commentators on the Holy Scriptures. He also wrote *A Treatise of some things which require to be Amended in the Company of Jesus*, Paris, 1625, in 8vo, reprinted with the Spanish text in the *Mercure Jésuitique.* This work was found amongst the papers of Mariana during his detention, and some copies of it were taken, which the enemies of the Society multiplied in France, in Italy, and in Germany. The Jesuits obtained its condemnation in 1631; but it is very doubtful whether Mariana had any share in the redaction of the obnoxious publication. Mariana left in manuscript several works, of which a catalogue will be found in the *Bibliothèque des Jésuites.* His

Historiæ was translated into English by Stevens, folio, London, 1699.

MARIANNA, or MARIANA, a town in the province of Minas-Geraes, Brazil, pleasantly situated between two eminences, at a height of 3000 feet above the sea, 45 miles N.E. of Ouro-Preto. The town is well built; and the principal streets are broad and well paved. The principal buildings are,—a cathedral, several other churches and convents, an ecclesiastical seminary, an hospital, and the bishop's palace. The trade is inconsiderable. Pop. 5200.

MARIANNE ISLANDS. See LADRONE.

MARIAS, LAS TRES, three islands in the North Pacific Ocean, lying off the W. coast of Mexico, and belonging to the state of Xalisco; between 21. and 22. N. Lat., and 106. and 106. 30. W. Long. They stretch in a line from N.W. to S.E.; and the largest of the three, which is the furthest to the N.W., is about 15 miles in length and 8 in breadth. The next island is about 24 miles in circumference, and the smallest, which lies to the S.E., has a circuit of 8 miles. These islands are barren and uninhabited, but they abound in wood, water, salt, and game, and were formerly often visited by English and American whaling vessels. They were visited by Diego de Mendoza in 1532, and named by him Isles de la Magdalena.

MARIAZELL, or ZELL, a market-town of Styria, circle of Bruck, is situated in the midst of mountainous and picturesque scenery, near the confines of Austria, about 55 miles S.W. of Vienna. It is only remarkable for a shrine of the Virgin, which every year attracts about one hundred thousand pilgrims. The town is meanly built, and contains about one hundred and twenty houses, of which forty-four are inns for the accommodation of pilgrims. Near the town are extensive iron-works. Pop. about 900.

MARIE ANTOINETTE, the daughter of Francis I., Emperor of Germany, and of the celebrated Maria Theresa of Austria, was born at Vienna 2d November, 1755. She had scarcely completed her fourteenth year, when the Duke de Choiseul was entrusted by Louis XV. to ask her in marriage for his grandson, the Dauphin of France, who afterwards, in 1774, became king under the name of Louis XVI. The marriage was celebrated at Versailles on the 10th of May 1770. But Marie Antoinette was not destined to experience much happiness at the corrupt court of France. Habituated from her earliest years, at the well-regulated court of Maria Theresa, to the enjoyment of privacy and domestic familiarity, she felt a strong dislike to the severe etiquette and stiff reserve which at the French court usurped the place of that candour and simplicity which almost invariably accompany purity of heart and true nobility of character. What was genuinely pure and noble was wellnigh unknown there; and gay frivolity and wanton licentiousness assumed a guise which was in some measure calculated to deceive the eye of the virtuous. This handsome, kind-hearted, lively and pure-minded German girl could with difficulty conceal her contempt for the heartless society among which she was cast. Prudence might have dictated less demonstration of her ridicule, less ostentation of her love for private life and the sweets of domestic affection; but her disposition was too spontaneous, her habit of mind too thoughtless for such a course, and she was consequently destined to multiply enemies rather than secure friends. Yet there was much in the young queen to attract the enthusiasm of her volatile subjects. If she disliked the stiff formality and polite insincerity of the court, her noble carriage and charming expression won the hearts of the people. When she appeared at first in public, the enthusiastic admiration of the populace was unbounded, and she had often to stand on the steps of her carriage and show herself to the admiring throng. But this interest was gradually dying away before the growing discontent of a distressed people, caused by the luxury of the court, and the exhaustion of the public treasury, when an incident occurred which gave the first direct blow to the popularity of Marie Antoinette. The Countess de la Motte having become aware that the queen had declined the offer of a magnificent diamond necklace from her jeweller, owing to the enormous price of 1,800,000 livres, which he demanded for it, the crafty countess, anxious to obtain possession of the treasure, alleged that she was authorized by the queen, and concluded the bargain. This unprincipled woman succeeded, besides, by a dexterous piece of intriguing, in making the Cardinal de Rohan a party to the negotiation, by beguiling him into the belief that he was met at midnight by Marie Antoinette in the park of Versailles. The fraud was discovered when the first payment was demanded; and, although the infamous countess was condemned to be whipped and branded for the wrong she had done her royal mistress, public suspicion was awakened, and the tongue of scandal let loose against the queen, who is now universally believed to have been innocent of the crimes laid to her charge. At the outbreak of the Revolution in 1789 she was regarded with an eye of jealous dislike by the public. She is said to have used all her efforts to induce her feeble and irresolute husband to offer resistance, but without success. She scorned to conciliate the favour of the revolutionary leaders, and even declined the aid of Mirabeau to support the royal interest; a step which drove that powerful orator and extraordinary man to enlist in the ranks of the Revolutionists. Marie Antoinette was imprisoned in the Temple after the popular triumph of the 10th August, 1792. She became known as one of the advisers of the attempted flight of the king, and this served to increase the jealousy and hatred of the public. The armed masses were resolved to annihilate the kingly office, and the poor unfortunate queen was exposed to all manner of insult and persecution. Nevertheless, she was not of a temper to be at once crushed by adversity; she displayed a dignified courage under the most trying circumstances, and exhibited a degree of moral firmness and mild resignation which was truly heroic. She was ever more anxious about the welfare of her husband and of her children than she was about her own. The royal family, on going to prison, had tried to persuade themselves that Danton was their friend, but the bloody fanaticism of the mob, led on by *Ami du peuple* Marat, soon extinguished any rays of hope that still may have lingered about the prison walls of this unfortunate family. The king was executed on the 21st of January, 1793, and on the following October, the "widow Capet," as the indictment called her, was tried by the tribunal of the Revolution. On appearing before that horrible court, she felt her doom was sealed; that no plea of innocence could save her; yet her fortitude and queenly dignity never forsook her. The foulest and most infamous charges were brought against her, calculated to outrage her feelings as a woman and a mother. Being urged to reply, she exclaimed, turning to the public with vehement indignation, "I appeal to all the mothers here present, and demand of them if this is possible." "This stroke," says a French historian, "was sublime; it produced a great effect; and the president, perceiving this, passed hastily to the other questions." She was, as a matter of course, found guilty and condemned to death; and on the 16th of October, 1793, she was removed from the prison of the Conciergerie, and conducted, bound on a cart, beside a priest and the executioner, to the place of suffering. The foul mockery of her trial was only surpassed by the heartless brutality of the ferocious mob that yelled and vociferated around her for two hours along the streets of Paris. Her trying imprisonment and severe suffering had wasted her strength and destroyed her beauty; her eyesight was greatly injured, and her hair had become quite white. She bore all the indignities which were thus publicly heaped upon her with singular firmness and mild dignity, inspiring even that savage mob with wonder and awe. She died by the guillotine on the 16th October, at the age of thirty-seven. Out of a family of four, two children survived her; a son, who subsequently died in prison, and a daughter, who afterwards became the Duchess of Angoulême.

MARIE-AUX-MINES, St, a town of France, department of Haut-Rhin, is situated on the Lieporette, 14 miles N.W. of Colmar. The town stretches for about a mile on both sides of the river, and on each side rise thickly wooded mountains which look down upon it. It possesses a council of *prud'hommes*, a chamber of manufactures, and a Protestant church. The neighbouring district was rich in mines, which in the middle ages produced silver, lead, and copper, in great quantities, though there is now remaining only one mine of argentiferous lead. The principal occupations now pursued in the town consist of the manufacture of linen, cotton, and woollen stuffs, especially handkerchiefs and calicoes. Bleaching, dyeing, paper-making, and tanning, are also carried on to a considerable extent. Pop. 11,600.

MARIE GALANTE. See GUADALOUPE.

MARIENBERG, a town in Saxony, circle of Zwickau, is situated at a height of 1980 feet above the level of the sea, 17 miles S.S.E. of Chemnitz, and 38 S.W. of Dresden. The town contains a church; two hospitals, one for orphans and one for miners; several other charitable institutions; besides an office for mines and a custom-house. It is famous for its mineral baths, and for mines of silver, iron, &c., which are worked to a great extent in the neighbourhood. The manufacture of lace and linen is also carried on here. Pop. 4895.

MARIENBURG, a town of West Prussia, government of Dantzic, is situated on the right bank of the Nogat, a branch of the Vistula, here crossed by a bridge of boats 546 feet long, 27 miles S.E. of Dantzic. It is surrounded by walls, and is principally important and interesting as having been the residence of the grand masters of the Teutonic Order of Knights. The ancient castle of the Order, which comprises also a palace and a church, is a splendid edifice in the Gothic style. It seems probable that the oldest part of it was built in the thirteenth century, when the King of Poland made a grant of this country to the knights. Additions were subsequently made to it in 1309, when the seat of the Order was transferred hither from Venice, and in 1335. In 1457 the castle was surrendered to the Poles, after having sustained several unsuccessful attacks in 1410 and 1420. On falling into decay, it was in 1815 restored by the present King of Prussia, and has since been kept in good preservation. The chapter-house, where all the meetings of the knights were held, is supported by a single granite pillar; and during the siege in 1410 the Poles attempted the destruction of the knights by aiming a cannon ball at the supporting column, when they knew that the grand master and his knights were assembled in conclave. The ball, which narrowly missed its aim, is still shown buried in the corner of the building. The church is a fine edifice in good preservation, and is chiefly remarkable for a mosaic figure of the Virgin on the outside of the wall. In the vaults beneath are buried many of the grand masters of the Teutonic Knights; and an extremely beautiful picture of the Virgin, by an unknown artist, which is kept here, is believed to possess miraculous powers. The town possesses in the present day little importance. It has a Roman Catholic and a Calvinist church, a normal school, and other educational and charitable institutions; as well as manufactures of cotton and woollen fabrics, and some trade in corn and wool. Pop. 7037.

MARIENWERDER, a government of West Prussia, is bounded on the N. by that of Dantzic, on the E. by that of Königsberg, on the S. by Poland and Posen, and on the W. by Brandenburg, with an area of 6759 square miles. The surface is for the most part level, and in some places marshy; but there are a few small hills scattered about in different parts. Much of the country is of no great fertility, and is ill cultivated; but near the rivers the soil is rich and fertile. The principal rivers are the Vistula, which is navigable, and its tributary the Brahe. No considerable mining operations are carried on in this district; nor are manufactures or commerce in a very thriving condition. The government is divided into thirteen circles; and the capital is Marienwerder, a neat town situated on the Liebe and little Nogat, 2 miles E. of the Vistula, and 43 miles S.S.E. of Dantzic. The town is chiefly notable for its old castle, now used as a court-house and prison; and for the cathedral, which has a spire of the height of 170 feet, and contains many ancient tombs of the Teutonic knights. The town also possesses a gymnasium, a school of architecture, an asylum for blind soldiers, another for their widows and children, an hospital, and a house of refuge for neglected children. The manufactures are not very extensive, and consist principally of linen and woollen stuffs, leather, hats, beer, and wines. Pop. of the government (1852) 649,548, of the town 7600.

MARIETTA, a town in the state of Ohio, capital of the county of Washington, North America, is situated at the confluence of the Muskingum and the Ohio, 115 miles S.E. of Columbus, and stands in a plain, surrounded with beautiful and picturesque scenery. It is well and regularly built, being greatly adorned by the neat gardens with which many of the houses are surrounded. Marietta contains seven or eight churches, two public libraries, a college founded in 1835, and two excellent academies. Within the last eight or nine years several manufactories have been established here, which have added much to the importance of Marietta. This town is the oldest in the state, and was first settled in 1788 by a body of New England colonists under General Putnam. Pop. (1850) 3175, (1853) about 4000.

MARINEO, a city of the kingdom of Naples, in the island of Sicily, and province of Mazzaro. It is situated on a gentle elevation, is very healthy, and is watered by the small River Bagaria. It contains 6540 inhabitants.

MARINI, MONSIGNOR GÆTANO, a celebrated savant, born in 1742 at St Arcangelo, near Rimini, in the Papal States. He began his studies under Giovanni Bianchi, and in early youth devoted himself to natural philosophy. He then turned his attention to mathematics, Greek, Hebrew, and classic literature; and afterwards, at the suggestion of his intimate friend Zerardini, applied himself to the study of jurisprudence, and went to Ravenna, where he took his degrees in Roman and ecclesiastical law. He did not, however, feel disposed to practise that profession, his tastes tending rather to philosophical and antiquarian research. To obtain leisure for these studies, he went to Rome in 1764, took holy orders, and dedicated himself to archæology. At that time the science of archæology was at its height in Italy. The recent discovery of Pompeii and Herculaneum had attracted the attention of princes as well as of the learned. Count Caylus had already classified the ancient monuments; Johann Winkelmann and the members of the Herculanenses Society had with equal taste and learning illustrated them; Ennio Quirino Visconti, the Nestor of art critics, had made them popular. The civilized West now began to turn its attention to the East, the cradle of mankind; and some of the most learned men of the time at Rome were engaged in philological, antiquarian, and numismatic researches, directed mainly towards the most interesting fields of inquiry in Egypt and the Asiatic continent, when Marini resolved to enlist in their ranks, and share their reputation.

He undertook to examine the ancient papyri, and among his many works, *I Papiri Diplomatici raccolti ed illustrati*, Roma, 1805, is that which principally entitles him to a high place among the savants of the eighteenth century. The first idea of this work belongs to Scipione Maffei; and though Zcrardini had previously attempted it, the honour of having accomplished this arduous task belongs entirely to Marini. It contains 146 Latin, and a few Greek diplomas or charters, extracted from papyri which he collected in Italy, France, and Vienna. Among these may be found papal letters addressed to the exarchs of Ravenna, charters by the Emperor Valentinian, by Chlodoveus, by Dagobert and Clothaire, kings of the Franks, by King Astolph and Adalgiso, interspersed with many other public and private documents. "Learned men," he says, "know the wonder felt by the ancients when they saw papyri two or three centuries old, but among ours there are some which date back fourteen or fifteen centuries." The oldest in fact belongs to the year 444. They were in a most dilapidated condition, and their interpretation is a monument of patience, talent, and learning. The researches which accompany this work, especially on the cultivation, traffic, and general use of the papyrus in Italy until the close of the eleventh century, even after the introduction of parchment, are very interesting and valuable.

Marini's next most important work is *Gli Atti de' Fratelli Arvali*, Roma, 1795, 2 vols. 4to, in which he collected and illustrated all the inscriptions and monuments which relate to the *Collegium Fratrum Arvalium*, an institution which, according to tradition, was coeval with the building of Rome, and founded, as Varro tells us, to propitiate the Divinity by public prayers, that the land might be rendered fertile (*sacra publica faciunt propterea ut fruges ferant arva*); whence *Arvales Fratres* or *Arvorum Sacerdotes*. This work is admirable for the acumen and learning displayed. The immediate cause of Marini's undertaking to investigate this subject was the discovery of two large marble tablets in the new sacristy of the Vatican chapel, which had been built by order of Pius VI. From these and various other inscriptions and monuments connected with that institution, he was enabled to find a clue to the ceremonies, rites, and fêtes; also the political connection of that remarkable body with the state, and hence to study their civil institutions, the duty of their municipal functionaries and provincial governors, to correct names, to determine the genealogy of many Roman families, &c., &c.; while discussions on ancient orthography, on the variation between the spelling and the pronunciation, the correction of old abbreviations in inscriptions, and the additions of new ones, find an appropriate place in this laborious and comprehensive work.

Marini's contributions to the scientific and literary history of Italy, to numismatics, to the elucidation of the Christian and pagan monuments, and of many unpublished documents in the Vatican, are all marked by the same sound criticism and unobtrusive but deep erudition. The most important of his minor works is that on the inscriptions in the Albani villas and palaces.

He obtained a well-earned celebrity both in Italy and abroad, and had honours and high offices conferred on him by several popes. He was appointed keeper of the *Biblioteca Vaticana* and prefect of the secret archives of the Holy See, was elected a member of the Institute of France and of the *Academie des Inscriptions et Belles Lettres*, as well as of all the scientific, literary, and archæological societies of Italy. He died at Paris on the 17th of May 1815, in his seventy-third year. (E. F.)

MARINO, San, or Sammarino, a republic in the N.E. of Italy, bounded on all sides by the Papal States, and situated about 10 miles from the Adriatic; area 24 square miles. It is not only the smallest in extent, but it is also the oldest of all the European states. In the year 469 Marinus, a Dalmatian hermit, originally a mason, is said to have settled here in the solitude of the mountains; and, having obtained from the owner a grant of territory, he was joined by a number of similar devotees, and thus gave origin and name to the little republic of San Marino. A village rose gradually; and in the tenth century it became a walled town, continuing independent of all foreign powers. In the civil wars of Italy, San Marino embraced the side of the Ghibeline or imperial party, and in the thirteenth century refused to pay certain taxes imposed by the pope. A dispute thereupon arose, which, on being referred to a learned judge of that day, was decided in favour of the republic; and San Marino has ever since been recognised by the popes as an independent state. Nor was any change made either on the conquest of Italy by Napoleon, or on the reinstatement of the pope in 1814. The legislature of the state consists of a large council of sixty, made up, in equal proportions, of nobles, townsmen, and small proprietors. This council is self-elected, and the members are chosen for life. Out of this a smaller council of twelve is chosen, and the executive power is in the hands of two *capitani reggenti*, who hold office for six months. The territory of the republic is entirely mountainous, and is watered by the Ausa and the Amarano, small streams which fall into the Adriatic. It produces wine, fruits, and silk. The town of San Marino, which stands on a mountain, the summit of which is crowned by a castle, is ill built and paved; and the streets are so steep as to be inaccessible for horses or carriages. The town has five churches, three convents, a town-house, and a large square commanding an extensive view. Besides the capital, San Marino has four villages. Pop. of state 7600.

MARIOTTE, Edme, a natural philosopher, was born in Burgundy in the seventeenth century. During part of his life he dwelt at Dijon, and from that place his first works are dated. He had studied for the church, and was afterwards chosen prior of St Martin, near Beaune. On the formation of the Academy of Sciences he became one of its members. He died in 1684. Mariotte was among the first French philosophers who turned their attention to experimental physics. In 1717 there was published at Leyden, in 2 vols. 4to, a collection of his works, comprising Treatises on Vegetation, on the Nature of the Air, on Heat and Cold, on the Nature of Colours, on Hydraulics, on a New Discovery touching the Sight, on Levelling, on the Motion of the Pendulum, on the Colours and Congelation of Water, and on Logic. (For an account of Mariotte's experiments on the density of the air, see *Dissertation Fifth*, ii. 2.)

MARITZA, a river of European Turkey. (See Hebrus.)

MARIUS, Caius, a celebrated Roman general, was born about B.C. 157, of poor parents, in Cereatæ (Plin. iii. 5.), a village near Arpinum, afterwards famous as the native town of Cicero. His youth seems to have been passed amidst the rude discipline of the camp; nor was his disposition at all softened by literature or by intercourse with the learned. He commenced his military career at Numantia (B.C. 134), and by his temperance and bravery so won the good opinion of Scipio, that that general answered one of his friends who inquired where they would find another general equal to himself, by putting his hand on the shoulder of Marius and saying, "Here he is." Many years, however, pass without any allusion to Marius, nor do we know what part he took in the troubled times of the Gracchi. He appears again in history as tribune of the people, B.C. 119, which office he is said to have obtained chiefly through the influence of the consul Metellus, whose implacable enemy he afterwards became. He began immediately to court the favour of the people, and proposed a law which tended to lessen the authority of the patricians in matters of judicature. The consul Cotta persuaded the senate to summon Marius to answer for his conduct; but the bold tribune threatened to send even the consuls to prison if they persisted in opposition to his measure. The senate gave way, and the law was subsequently confirmed by the people. He was thus supposed to have embarked in the popular cause; but this opinion changed when it was found that he strenuously opposed the distribution of corn amongst the people. When his year of office had expired, he stood as candidate for the curule ædileship, but was rejected; upon which he applied for the plebeian ædileship, and in this too he was unsuccessful. Not long afterwards he stood for the prætorship, and was returned last of the six, and not without the suspicion of bribery. He was tried, and escaped only by an equality of votes. The following year he was sent as proprætor to Farther Spain, which he soon cleared of the banditti who infested the province. On his return to Rome he was anxious to take part in the administration of public affairs, but he had neither riches to buy favour, nor eloquence to command it. Still, by his high spirit, by his indefatigable industry, and simple mode of living, he became a favourite with the people, and acquired sufficient reputation to be thought worthy of marrying Julia, the aunt of Julius Cæsar. When Metellus was appointed, B.C. 108, to the command of the war against Jugurtha, he chose Marius as one of his lieutenants. Selfish enough to feel no gratitude for his promotion, and to be wholly intent upon his own advancement, Marius strove by every method to convince the soldiers of the faults of Metellus, and of the merits of himself. When he had thus succeeded in persuading all that he alone was able to terminate the war, he determined to stand as candidate for the consulship, and pressed Metellus to grant him leave of absence to proceed to Rome. Metellus ridiculed his pretensions to such a high office, and, laughing, asked him if he would not be satisfied to stay and be consul with his son, who was then very young. At last, however, he granted permission only twelve days before the election; but favoured by the winds, Marius reached Rome in six days. His recently acquired fame had gone before him, and the people elected him consul, B.C. 107, with great applause. He was commissioned to supersede Metellus in the province of Numidia; and while levying an army, he enlisted, in opposition to the usual custom, all persons, however ignoble, who offered themselves. He then returned with his troops to Africa, but did not reap the glory which he had expected, for he was in a great measure deprived of it by his quæstor Sylla. Jugurtha had fled to his father-in-law Bocchus, King of Mauritania; and that prince, after some deliberation, delivered him alive (B.C. 105) into the hands of Sylla. (See JUGURTHA.) It was this circumstance which laid the foundation of that violent and implacable quarrel between Marius and Sylla which almost ruined the republic. Italy was at this time threatened by an invasion from the Cimbri and Teutones, a horde of northern barbarians who had overrun the whole of Gaul. The Romans were in the utmost consternation, and no one seemed able to protect them but Marius. Though absent, he was elected consul a second time, B.C. 104, and received orders to return home with his army. On his arrival he obtained the honours of a triumph, and then devoted himself to the discipline of the levies which he raised. The barbarians meanwhile had passed into Spain, and during the whole of this year Italy had a respite from her enemies. At length, in 102 B.C., shortly after Marius had been elected consul for the fourth time, they approached with an overwhelming force the northern frontiers of Italy. Marius hastened across the Alps, and pitched his camp near the mouth of the Rhone. The camp was fortified and well provisioned; and, that it might communicate with the sea, he employed his men in making a canal capable of receiving ships of considerable burden. Meanwhile the barbarian army had divided. The Cimbri marched in the direction of the Tyrol to attack Catulus. The Teutones and Ambrones advanced to storm the camp of Marius. That general, in order that his army might become inured to the wild aspect of the savages, remained inactive until they were compelled by lack of provisions to abandon the siege, and press forward to Italy. He then left his camp, hovered about their rear, and seizing a favourable opportunity, attacked them at Aquæ Sextiæ (*Aix*), and after a desperate conflict, routed them with immense carnage. The wives and those who had escaped from the battle put an end to their lives. Whilst he was sacrificing in honour of this victory he received intelligence that he had been elected fifth time consul, B.C. 101.

Marius returned to Rome, where he was offered a triumph, which he declined. He then proceeded to the assistance of his late colleague Catulus, who was guarding the north of Italy against the Cimbri. His arrival gave confidence to Catulus; and as soon as the army from Gaul arrived, they crossed the Po to check the barbarians who were ravaging the country on the opposite side. The Cimbri deferred the combat till the arrival of the Teutones, whom they were unwilling to believe to have been destroyed; and in the meanwhile sent to demand lands and cities from Marius, which should be sufficient for themselves and brethren. "Your brethren," said Marius, "have land enough which we have already given them, and they shall have it for ever." A decisive battle was fought a short time afterwards (30th July) in the plain of Vercellæ; and though the victory was almost wholly due to the bravery and good conduct of Catulus, Marius carried off all the honour, and was named the third founder of Rome. On his return to Rome he enjoyed the honour of a triumph, along with his colleague Catulus. He then began to exert all his influence to get himself re-elected to the consulship, and he omitted no means, however dishonourable, that might conduce to his success. Marius succeeded (B.C. 100) for the sixth time, and one of his first acts was the banishment of his old enemy Metellus by a mean and treacherous device. So unpopular had Marius now become, that he refused to stand as a candidate for the censorship, lest he should suffer a repulse. Metellus was recalled next year, and that he might not witness his triumphant entrance, Marius left Rome for the East, under the pretence of performing some vow to the mother of the gods, but in reality to excite Mithridates against the Romans. For ten years Marius was disconnected with public affairs; but when the Marsian or Social War broke out (B.C. 90), he was appointed to the command. Age, however, had quenched his martial ardour, and his reputation suffered as much as that of Sylla increased. When the Social War had been concluded, B.C. 88, the Romans saw that they must commence the contest with Mithridates. The enmity of Marius and Sylla now broke out in open war, as they were both anxious to be appointed to the command. Sylla was supported by the senate, but Marius excited a sedition through the tribune Sulpitius, and received the appointment; on which Sylla, refusing to lay down his command, and backed by his whole army, marched to Rome and overawed his enemies. Marius with great difficulty embarked on board a small vessel at Ostia, which was ready to sail for Africa, but contrary winds obliged him to land at the mouth of the Liris (*Garigliano*) where he was abandoned by the sailors. There he was discovered lurking in a marsh, and was dragged to Minturnæ with a rope round his neck, and with his face and garments begrimed with mud. The authorities of the town resolved to put him to death, but could find no man willing to accomplish their wish. At length a Cimbrian horse-soldier offered his services, and entered the room of the captive with his sword drawn in his hand. But when Marius, fixing upon him his commanding eye, exclaimed, Marivaux.

"Dost thou dare to kill Marius?" he flung down his weapon and fled. The people of Minturnæ then persuaded their magistrates to banish Marius, and a vessel was found to bear him from his country. He proceeded to Ænaria (*Ischia*), and thence to Africa. He landed at Carthage; and whilst he was seated there, a messenger came from the governor Sextilius with an order that he should leave the province. "Go and tell him," said the unfortunate man, "that you have seen the exiled Marius sitting on the ruins of Carthage." Marius proceeded to Cercina, a small island not far from the continent, and here received intelligence that the consuls Cinna and Octavius, having quarrelled, had had recourse to arms. Marius determined to proceed to the assistance of Cinna, who had been driven by his colleague from Rome; and landing with a considerable body of exiles, he soon changed the face of affairs, and reinstated Cinna in his office. He himself refused to enter Rome till the decree of his banishment was repealed. This affected deference to the laws of his country was soon laid aside, and the streets of Rome flowed with the blood of the best of her citizens. Marius was elected consul for the seventh time, B.C. 86; but his age and infirmities rendered him little able to sustain the weight of public affairs. The intelligence that Sylla was returning victorious from the Mithridatic war alarmed him, and drove him for relief to intoxication. This hastened his end, and he died on the seventeenth day of his seventh consulship, B.C. 86, at the age of seventy. His ashes were thrown into the Anio by the order of Sylla. The Life of Marius has been written by Plutarch; that by Rutilius Rufus has been lost. An account of the proscription of Marius may be found in Appian.

MARIVAUX, PIERRE CARLET DE CHAMBLAIN DE, one of the most prolific and ingenious writers of the eighteenth century in the department of comedy and romance, was descended from an ancient family of Rouen, and was born at Paris in the year 1688. Young Marivaux early gave evidence of the subtilty and activity of his genius, which was carefully developed by all the appliances of an excellent education. The society to which he was introduced on his entrance into life exercised a sensible influence on the character of his writings. Admitted into the *salons* of the opulent females of the capital, who then vied with each other in protecting men of letters, he there contracted that affectation of wit, of which the comedies of Molière had not yet entirely cured the *précieuses* of the age. It was there that he became acquainted with Lamotte and the numerous writers who composed the salon of Madame de Tencin, and whom that celebrated woman familiarly called her "beasts." It was in this society that Marivaux, naturally inclined to controversy, and fond of paradox, though otherwise gentle and tolerant, amused himself in tilting with the partisans of antiquity, depreciating poetical talent, and deriding the admirers of Voltaire. He even went so far as to maintain that Molière did not understand comedy, and pretended that he could not conceive how people should admire the *Tartuffe* and the *Femmes-Savantes*. Living in the world at a period when Pyrrhonism in matters of religion was the fashion, he combated, without asperity, but with laudable zeal, that truly deplorable mania. "Ah, my God," said he on one occasion to a freethinker, who was otherwise an honest man, "take not from poor humanity that consolation which Providence has reserved for it." If he was slightly tinctured with vanity, he was also distinguished for magnanimous disinterestedness and severe probity. He died at Paris on the 12th of February 1763, at the age of seventy-five. He had been unanimously admitted a member of the French Academy in 1743, and had Voltaire for a competitor. Marivaux's dramatic pieces, while displaying much talent, are nevertheless inferior to his romances. He never surpassed his *Marianne*, or his *Paysan Parvenu*; delineations which, although characterized by the peculiar manner of the writer,—what the French call *marivauxdage*,—yet interest and charm the reader by their subtle knowledge of the human heart, and by their accurate and masterly touches of character.

To the Théâtre-Italien he contributed.—*L'Amour et la Vérité*, 1720; *Arlequin poli par Amour*, 1720; *La Surprise de l'Amour*, 1722; *La Double Inconstance*, 1723; *Le Prince Travesti*, 1724; *L'Ile des Esclaves*, 1725; *L'Hérétier de Village*, 1725; *Le Triomphe de Plutus*, 1728; *La Nouvelle Colonie, ou la Ligue des Femmes*, 1729; *Jeux de l'Amour et du Hazard*, 1730; *Le Triomphe de l'Amour*, 1732; *L'Ecole des Mères*, 1732; *L'Heureux Stratagème*, 1732; *La Méprise*, 1734; *La Mère Confidante*, 1735; *Les Fausses Confidences*, 1736; *La Joie Imprévue*, 1738; *Les Sincères*, 1739; and *L'Epreuve*, 1740. The dramatic works of Marivaux, originally represented at the Théâtre-François, are somewhat less numerous. They consist of *Annibal*, a tragedy, 1720; *Le Denouement Imprévue*, a comedy, 1724; *L'Ile de la Raison, ou les Petits Hommes*, derived from the romance of Gulliver, 1727; *La Surprise de l'Amour*, 1727; *La Réunion des Amours*, 1731; *Les Serments Indiscrets*, 1732; *Le Petit-Maître Corrigé*, 1734; *Le Legs*, 1736; *La Dispute*, 1744; and *Le Préjugé*, 1746. His romances consist of,—*Don Quichotte Moderne; Effets Surprenants de la Sympathie; La Vie de Marianne; La Paysan Parvenu; Le Philosophe Indigent*. His works were collected and published in 12 vols., Paris 1781, in 8vo.

Mark.

MARK, ST, *the Evangelist*, is, according to ecclesiastical testimonies, the same person who, in the Acts, is called by the Jewish name John, whose Roman surname was Marcus (Acts xii. 12, 25). He was a convert from Judaism, and the cousin of Barnabas, and was most probably of Jewish descent. We find his mother Mary a resident in Jerusalem, and entertaining the apostles at her house (Acts xii. 12). He accompanied Paul and Barnabas on their travels as an assistant (Acts xii. 25; xiii. 5), but afterwards left them and returned to Jerusalem. On this account Paul refused to take Mark with him on his second apostolical journey, but subsequently became reconciled to him, and he was present with the apostle during his captivity at Rome.

There is a unanimous ecclesiastical tradition that Mark was the companion and ἑρμηνευτής of Peter. This epithet, according to A. Tholuck, was applied to Mark because he was the assistant of Peter, and either orally or in writing communicated and developed what Peter taught. This tradition is the more credible, as the New Testament does not contain any passage that could have led to its invention; and, moreover, the testimony in favour of the connection between Mark and Peter is so old and respectable, that it can with difficulty be called in question. It first occurs at the commencement of the second century, and proceeds from the presbyter John (Euseb., *Hist. Eccles.* iii. 39); it afterwards appears in Irenæus (*Adv. Hær.* ii. 1. 1, and x. 6); in Tertullian (*Contra Mart.* iv. 5); in Clemens Alexandrinus, Jerome, and others. Eusebius infers (*Hist. Eccles.* ii. 15) from the later life of Mark, that he was with Peter at Rome. Epiphanius and others inform us that he introduced the gospel into Egypt, founded the church at Alexandria, and that he died in the eighth year of Nero's reign. This apostle is the author of the gospel which goes by his name.

MARK, ST, *Gospel of*, the same ancient authors who call Mark a μαθητής (disciple) and ἑρμηνευτής (secretary) of Peter, state also that he wrote his gospel according to the discourses of that apostle. The most ancient statement of this fact is that of the presbyter John and of Papias, which we quote from Eusebius (*Hist. Eccles.* iii. 39) as follows:—"Mark having become secretary to Peter, whatever he put into style he wrote with accuracy, but did not observe the chronological order of the discourses and actions of Christ, because he was neither a hearer nor a follower of the Lord; but at a later period, as I have said, wrote for Peter to meet the requisites of instruction, but by no means with the view to furnish a connected digest of the discourses of our Lord." Schleiermacher, and after him Strauss, have turned this into an argument against the gospel of Mark. They assert that this gospel is a συντάξις, which, if not chronological, is at least a concatenation according to the subjects. Now the presbyter John states that Mark wrote οὐ τάξει, *without order*. We learn, however, from what Papias adds, how Papias himself understood the words of the presbyter; and we perceive that he explains οὐ τάξει by ἔνια γραψας, *writing isolated facts*. Hence it appears that the words οὐ τάξει signify only incompleteness, but do not preclude all and every sort of arrangement.

If the opinions concerning the relation of Mark to Matthew and Luke, which have been current since the days of Griesbach, were correct, we might be able to form a true idea concerning the chronological succession in which the first three gospels were written. The chronological order of the gospels is, according to Origen, the same in which they follow each other in the codices. Irenæus (*Adversus Hæreses*, iii. 1.) states that Mark wrote after the death of Peter and Paul; but, according to Clemens Alexandrinus (*Hypotypos.* vi.) and Eusebius (*Hist. Eccles.* vi. 14), he wrote at Rome while Peter was yet living. Griesbach, Saunier, Strauss, and many others, however, state it as an unquestionable fact, that the Gospel of Mark was merely an abridgement of the Gospels of Matthew and Luke. Weisse, Wolke, and Bauer, on the other hand, have in recent times asserted that the Gospel of Mark was the most ancient of all the gospels, that Luke amplified the Gospel of Mark, and that Matthew made additions to both.

We do not see any reason to contradict the unanimous tradition of antiquity concerning the dependence of Mark upon Peter. We deem it possible, and even probable, that Luke read Mark, and that he also alludes to him by reckoning him among the *many*, who had written gospel history before him. This supposition, however, is by no means necessary or certain; and it is still possible that Mark wrote after Luke. Some of the ancient testimonies, namely, those of Irenæus, Clemens Alexandrinus, Jerome, and others, state that Mark's gospel was written at Rome. In favour of this opinion there have been urged some so-called Latinisms; for instance, in ch. xv. 15, and ch. v. 23. These expressions are, however, rather Græcisms than Latinisms. Others appeal to words which have a Latin origin; but these are military terms which the Greeks adopted from the Romans. These Latinisms cannot prove much, however, respecting the locality in which Mark's gospel was written; but it is certain that it was written for Gentile Christians. This appears from the explanation of Jewish customs (ch. vii. 2, 11; xii. 18; xiii. 3; xiv. 12; xv. 6, 42). The same view is confirmed by the scarcity of quotations from the Old Testament, perhaps also by the absence of the genealogy of Christ, and by the omission of the Sermon on the Mount, which explains the relation of Christ to the Old Testament dispensation, and which was, therefore, of the greatest importance to Matthew.

The characteristic peculiarity of Mark as an author is particularly manifest in two points: 1. He reports rather the works than the discourses of our Saviour; 2. He gives details more minutely and graphically than Matthew and Luke; for instance, he describes the cures effected by Jesus more exactly (iv. 31, 41; vi. 5, 13; vii. 33; viii. 23). He is also more particular in stating definite numbers (v. 13, 42; vi. 7; xiv. 30), and furnishes more exact dates and times (i. 32, 35; ii. 1, 26; iv. 26, 35; vi. 2; xi. 11, 19, 20, &c.).

Most of the materials of Mark's narrative occur also in Matthew and Luke. He has, however, sections exclusively belonging to himself, viz., iii. 21, 31, sq.; vi. 17, sq.; xi. 11; xii. 28, sq. These peculiar statements of Mark have an entirely historical character: consequently we deem it unjustifiable in Strauss and De Wette to endeavour to depreciate them by calling them arbitrary additions.

We may mention respecting the conclusion of Mark's gospel (ch. xvi. 9, 20), the genuineness of which, from its omission in several of the codices, has been called in question, that Michaelis and Hug are of opinion that the addition was made by the evangelist at a later period, in a similar manner as John made an addition in ch. xxi. of his Gospel. Perhaps also an intimate friend, or an amanuensis, supplied the defect. If either of these two hypotheses is well founded, it may be understood why several codices were formerly without this conclusion, and why, nevertheless, it was found in most of them.

Among the various commentaries on the Gospel of Mark which have been published in modern times, the following deserves to be specially mentioned:—*Evangelium Marci recensuit, et cum Commentariis perpetuis edidit*, C. F. A. Fritsche, Lipsiæ, 1830. On the whole subject consult *An Introduction to the New Testament*, by Dr S. Davidson, London, 1848; also *The Origin of the Gospels*, by James Smith, Esq., F.R.S., Edinburgh, 1853. For a compendium of all critical investigations into the history contained in the gospels consult Ebrard's *Wissenschaftliche Kritik der Evangelischen Geschichte*, 2 vols. 1842.

MARKET-HARBOROUGH, a market-town of England, in the county of Leicestershire, on the left bank of the Welland, 15 miles S.S.E. of Leicester, and 83 N.W. of London. The town consists of one principal street, and several smaller ones; and it is well paved and lighted. It contains a town-hall; a handsome church of the fourteenth century, with a tower and a lofty octangular spire; places of worship for Wesleyan Methodists, Independents, and Baptists; national and British schools, a free school, &c. A silk mill and several breweries are in operation, but the inhabitants are chiefly employed in agriculture. A carpet manufactory, which formerly existed here, has been discontinued, and the wool, on being prepared here, is now sent to London to be made into carpets. Market-Harborough is mentioned in history as the head-quarters of the royalists before the battle of Naseby. It is connected with London by the North-Western and Rugby and Stamford Railways. The market-day is Tuesday; and fairs are held twice a-year. Pop. (1851) 2325.

MARKINCH, a village and parish in Fifeshire, Scotland, situated not far from the Leven, 7 miles N. of Kirkcaldy. The town contains a parish church, a Free, and a United Presbyterian church, and two schools. Coal is worked to a considerable extent in the parish; and there are also paper, woollen, linen, and flax mills, and bleachfields. The parish includes also the villages of Milton and Thornton. Markinch was formerly a residence of the Culdees. Pop. of parish (1851) 5843.

MARKLAND, JEREMIAH, one of the most learned scholars and acute critics of his age, was born in 1692 at Childwall in Lancashire, and received his education in Christ's Hospital, and at St Peter's College, Cambridge. Having taken his degree of M.A. in 1717, he soon after became a fellow and tutor in his college, a position which he subsequently resigned for that of a travelling tutor on the Continent. He became first publicly known by his *Epistola Critica*, addressed to Bishop Hare. In this he gave many proofs of extensive erudition and critical sagacity. He afterwards published an edition of the *Sylvæ* of Statius (London, 1728), and the *Supplices* (1763) and *Iphigenias* (1771) of Euripides; and he assisted Dr Taylor in his editions of Lysias and Demosthenes by the notes which he communicated to him. He also very happily elucidated some passages in the New Testament, which may be found in Mr Boyer's edition of it; and he was author of a volume of valuable remarks on the Epistles of Cicero to Brutus, and of an excellent little treatise under the title of *Quæstio Grammatica*. He died in 1776 at Milton, near Dorking in Surrey, where he had spent the greater part of a long life in the closest retirement, admired alike as a scholar and as a man.

MARLBOROUGH, a municipal and parliamentary borough and market-town of England, Wiltshire, on the left bank of the River Kennet, 13 miles N.W. of Devizes, and 75 W. by S. of London. The town consists of one main street of considerable breadth, which is crossed by other smaller ones. The houses are for the most part old and irregularly built, and many of them have curiously carved gables. The principal buildings are,—the market-house, an old building, in the upper part of which there are the council chamber, assembly rooms, and court-house; the college buildings; an old church of St Mary, built in the Norman style, with a low square tower; and an elegant modern church. There are, besides, places of worship for Wesleyan Methodists and Independents, &c., a free grammar school, national and other schools. Marlborough college was incorporated in 1845 for the education of sons of clergymen and others. A considerable commerce is carried on here, principally in coal, corn, and malt; but since the opening of the Great Western Railway the town has lost much of the importance which it derived from its situation on the high road between London and Bath. In all probability, the Roman station *Cunetio*, founded by Antoninus, was in the neighbourhood of Marlborough. Henry III. held a Parliament here, at which were enacted those laws called the Statutes of Malbridge. The borough received its first charter in 1205. It is governed by a mayor, four aldermen, and twelve councillors; and it sends two members to Parliament. Markets are held on Saturday, and fairs three times a-year. Pop. of the municipal borough (1851), 3689; of the parliamentary borough, 5135.

MARLOW, GREAT, a municipal and parliamentary borough of England, county of Buckingham, on the north bank of the Thames, 23 miles S. by E. of Aylesbury, and 31 W. by N. of London. The town consists of two principal streets at right angles to each other, and meeting in a large square, besides several smaller ones. The principal buildings are the town-hall, and the parish church, opened in 1835, and surmounted by a lofty spire. There are also places of worship for Wesleyan Methodists, Independents, Baptists, and Roman Catholics; national schools; charity schools; and other benevolent institutions. The river is here crossed by a handsome suspension bridge, with a span of 75 yards. The town possesses paper-mills and breweries; and the trade, which is considerable, consists chiefly of corn, coals, and timber. The markets have been discontinued; but large fairs are held here for horses and cattle; and there are races in August. Marlow returns two members to Parliament. Pop. of the municipal borough (1851) 4485, of the parliamentary borough (1851) 6523.

MARLOWE, CHRISTOPHER, the "Kit Marlowe" of Elizabethan wits and poets, was born at Canterbury in 1564. His birth is registered under the date of February 26, so that he was not two months older than his great contemporary in the drama, Shakspeare. Marlowe's father was a shoemaker, but he had interest enough to obtain for his son admission into King's School, Canterbury, which insured him five years' liberal education and a sum of L.4 per annum, equal to L.20 of our present money. He was entered as a pensioner of Bennet College, Cambridge, March 17, 1581, and took his degree of M.A. in 1587. Before this time Marlowe had written the first part of his tragedy of *Tamburlaine*, which was attacked in 1587 by Greene and Nash as an attempt to "outbrave better pens with the swelling bombast of blank verse." In the prologue to his play Marlowe had challenged attention to his innovation:—

> "From jigging veins of rhyming mother-wits,
> And such conceits as clownage keeps in pay,
> We'll lead you to the stately tent of war,
> Where you shall hear the Scythian Tamburlaine
> Threatening the world with high astounding terms."

Marlowe kept his word with the audience. The tragedy is full of extravagant scenes in Persia, Scythia, Morocco, &c., in which Tamburlaine is drawn in a chariot to which captive kings are harnessed, and even death is represented as afraid to face the conqueror! There is great power of expression, and some gorgeous local painting, in the drama, and its success was unprecedented. A second part was soon produced, and both were printed in 1590. Tamburlaine was followed by the *Tragical History of the Life and Death of Dr Faustus*, the *Massacre at Paris*, the *Rich Jew of Malta*, and the *Troublesome Reign and Lamentable Death of Edward the Second.* Marlowe also aided Nash in another tragedy, *Dido Queen of Carthage.* Besides his plays, all of which were highly successful, Marlowe translated part of the poem of *Hero and Leander*, from Musæus (afterwards completed by Chapman), the first book of *Lucan*, and Ovid's *Elegies*,—the last in so licentious a style that it was burned by order of the Archbishop of Canterbury. The beautiful little pastoral song, "Come live with me, and be my love," quoted in Izaak Walton's *Angler*, was also of Marlowe's composition. He had thus not only the tragic pomp and "mighty line" of the dramatic muse, but the gentler graces of the poet and lover of nature. His chief strength, however, consisted in depicting the passions —in awakening terror, pity, grief, and remorse, which, before his day, were unknown to the English stage. The latter scenes of *Faustus*, and the death-scene of *Edward II.*, are unsurpassed, even in Shakspeare, for their strong interest and sublimity. Passages of fine poetical and rhetorical beauty also relieve his darker delineations of character and daring flights of imagination; and there is little doubt that, if Marlowe had lived till his powers had been chastened and matured, Shakspeare might for once have found a rival. But Marlowe was wild and dissipated, entertaining atheistical opinions, according to his wretched associate in debauchery, Robert Greene, and numerous zealots; and he was cut off by a violent death when little more than twenty-nine years of age. One Francis Archer, a serving-man, and rival in Marlowe's "lewd love," as Meres states, had invited him to a feast at Deptford. A quarrel probably arose, for Marlowe attempted to stab his host with his dagger, while the other seized him by the wrist, and turned the dagger so that it entered Marlowe's eye, and pierced him to the brain. He died shortly afterwards, June 16, 1593.

It is usual to term Marlowe the precursor of Shakspeare. He had the priority in the use of sonorous and energetic blank verse. They were, however, of the same age; and as the great dramatist had produced at least twelve of his original plays before 1598, it is natural to infer that he had begun to write some time before Marlowe's death in 1593. He may have been engaged even as early as 1587, when *Tamburlaine* appeared, in adapting his historical dramas of *Henry VI.* and *Richard III.*, and the *Taming of the Shrew;* all which are modelled so closely on the old plays that above 2000 lines have been appropriated entire by Shakspeare. Many passages in these old plays are also found in Marlowe's *Edward II.* Stage effect was then chiefly studied; the plays were produced to be acted, not read; and so many additions were made—at least to the inferior dramas—by subsequent writers engaged by the managers, that considerable uncertainty hangs over their literary history. That Shakspeare had at first "beautified" himself by "feathers" taken from Greene or Marlowe, or both, we have shown by extracts given in the life of Greene; but his style—the garb, as it were, of his unapproachable genius—was soon distinctly formed, and the characteristics of Marlowe are also manifest in his best plays. The individuality of either cannot be mistaken; and Marlowe, however inferior, has the striking merit of originality and command of the grander elements of tragedy. (R. C—S.)

MARMANDE, a town of France, capital of an arrondissement of the same name in the department of Lot-et-Garonne, is pleasantly situated on the right bank of the Garonne, which is here crossed by a bridge with a single arch, 30 miles N.W. of Agen. Marmande has rather an antiquated appearance, many of the houses being timber-framed; but it is at the same time neat, clean, and regular, and has several fine squares and public fountains. The principal buildings are the town-hall, the court-house, and the college. The manufactures chiefly carried on here are those of hats, woollen stuffs, brandy, ropes, and leather. The Garonne is navigable as far as Marmande, and the harbour is very good. The trade is very flourishing, and consists of corn, flour, wines, tobacco, &c. Marmande is an ancient town. Having supported the cause of the Albigenses, it was taken after a disastrous siege, in 1219, by Louis VIII. and Amaury de Montfort, when most of its inhabitants were put to the sword. It was afterwards besieged in 1577 by Henri IV. Pop. (1851) 8257.

MARMONT, AUGUSTE FREDERIC LOUIS VIESSE DE, *Duc de Raguse*, Marshal of France, was born at Chatillon-sur-Seine on the 20th July 1774. At the age of fifteen he entered the army as sub-lieutenant of infantry, and in 1792 passed with the same rank into the artillery. In the following year his skill and bravery before Toulon introduced him to the notice of Bonaparte, and laid the foundation of his fortunes. He was promoted to the rank of captain in 1794, and having entered the army of the Rhine in 1795, he showed great valour at the blockade of Mayence. He then accompanied Napoleon as his principal aide-de-camp in the Italian campaign of 1796; and by his brave and skilful conduct at Lodi, Castiglione, and Saint Georges, earned his promotion to the rank of colonel, and the distinction of being sent to Paris with the captured colours. His rise became more rapid amid the toils and perils of the Egyptian expedition in 1798. For the part he acted during the capture of Malta he was created a general of brigade; and after he had distinguished himself at the battle of the Pyramids, he was appointed commander of Alexandria. He returned with Bonaparte to France in 1799, and was a zealous supporter of that general on the day of the 18th Brumaire. Shortly after this he was appointed a councillor of state and commander-in-chief of the reserve of the artillery. In this latter capacity he superintended the famous crossing of the Great St Bernard in the spring of 1800. His important share in the victory of Marengo, which was gained in the following June, raised him to the rank of a general of division. Appointed commander of the army in Dalmatia in 1806, Marmont defeated the Montenegrins, Greeks, and Russians, at Castel-Novo, and governed the duchy with so much tact and success, that he received the title of Duc de Raguse in 1808. In the following year he was summoned by Napoleon to assist in the war against Austria, and won his marshal's baton on the battle-field of Wagram. The organization of the Illyrian provinces was a result of that decisive victory, and Marmont was appointed their governor. From this office he was called in 1811 to supersede Massena in the command of the army in Portugal. There his administration was characterized by his usual ability, but not by his usual success. He was defeated by Wellington at the battle of Salamanca in 1812, and enfeebled by wounds and fatigue, he was forced to return to Paris. Summoned into action once more in 1813, Marmont fought at Lutzen, Bautzen, and Wurtzen; and while covering the retreat of the French after the disastrous battle of Leipsic, he was again wounded. In 1814, with a comparatively small force, he resisted for several hours the entrance of the allies into Paris, and not until he was nearly overborne by the numbers of the enemy did he agree to evacuate the city. Yet so much odium did he incur on account of this capitulation, that he was excepted by name from the general amnesty which Napoleon proclaimed on his return from Elba. Marmont accordingly retired to Aix-la-Chapelle during the Hundred Days, and did not return to Paris until after the battle of Waterloo. He was then nominated a major-general of the royal guard; and in 1817 he was commissioned as the king's lieutenant to allay an insurrection in Lyons. About this period he retired into the country, and devoted himself to agricultural pursuits until 1825, when he was despatched as ambassador extraordinary to congratulate Nicholas on his accession to the throne of Russia. During the Revolution he commanded, though very unwillingly, the king's troops. Having thus become the object of popular indignation, he was driven into exile on the expulsion of Charles X., and his name was struck off from the list of marshals. He latterly devoted much attention to the study of the military systems of different countries. Part of his information on this subject he published in his *Esprit des Institutions Militaires*, Paris, 1845. He died at Venice in 1852. Two volumes of his Memoirs, written by himself, were lately published in Paris.

MARMONTEL, JEAN FRANÇOIS, a celebrated French writer, was born in 1723 at the picturesque village of Bort in the Limousin, in a family little removed above the rank of peasantry. He owed the early part of his education to private charity and gratuitous public institutions. After studying at the college of the Jesuits at Clermont, he went to Toulouse, where he delivered lectures in philosophy with considerable reputation, and gained an academical prize. An accidental correspondence with Voltaire finally led to his departure for Paris in 1745, where he obtained the personal acquaintance of that highly popular writer, who at that time extended the most friendly encouragement to all young men possessed of any talents for poetry. There Marmontel commenced his career of letters by gaining a prize for a poem on a subject proposed by the French Academy, *La Gloire de Louis XIV. perpetuée dans le Roi son Successeur*. But in that age the theatre afforded the most ample field for the acquisition of wealth and eminence, and he accordingly next turned his attention to theatrical composition. His first tragedies, *Dionysius* and *Aristomenes*, obtained a flattering reception, but were soon forgotten; and his succeeding ones, *Cleopatra*, the *Heraclides*, and *Numitor*, had no success whatever. Laharpe, who was a great dramatic critic, condemns them all as bad, except the *Heraclides*, which he calls a tolerable tragedy of the second rank. In fact, Marmontel does not appear to have been endowed with any great talents for poetry or dramatic composition. His dramatic writings, however, gained for him at once both friends and fortune, and he found himself suddenly elevated from the verge of utter want, and at once plunged into all the bustling intrigue of the first literary circles, and into all the glare and dissipation of fashionable society. His time was occupied with rehearsals, love intrigues, and parties of pleasure. By addressing flattering verses to the king, and gaining the favour of other persons of influence, Marmontel obtained the situation of under-secretary of the royal buildings. This employment fixed his residence at Versailles for five years, during which time he contributed articles to the *Encyclopédie*, which were afterwards printed together in alphabetical order, under the general title of *Elements de Littérature*. He afterwards commenced the *Contes Moraux*, written originally for the *Mercure de France*, which were subsequently collected and printed by themselves. Many of these tales, on which the fame of Marmontel principally, if not solely, rests, bear reference to the original idea with which they commence, being for the most part intended to expose some absurdity or extravagance of character. In most of them he displays a very happy imitation of nature in the manners and in the language; and it is only to be regretted that he has occasionally given too high a colouring to conceptions of the most beautiful simplicity. As lively pictures of French manners, both simple and fashionable, they are admitted to be unrivalled. Having been suspected of writing a satire against some powerful nobleman, in the *Mercure*, of which he had now become the sole manager, he was, in consequence, shut up for a few days in the Bastille, and on his release deprived of his agreeable and lucrative situation. He next translated into prose the *Pharsalia* of Lucan, and added to it a supplement, in which he details the events of Cæsar's wars in Africa, and concludes with his last campaign in Spain. His next publication was a romance called *Bélisaire*, which, on its first appearance in 1768, attracted universal attention, and involved the author in a dispute with the Sorbonne, who published a censure of it, which was opposed by the arguments of Turgot, and by the epigrams and squibs of Voltaire. He some time afterwards produced his *Incas of Peru*, and, irritated as he was by the recent anathemas of the Sorbonne, his great object in this new romance was to show, that all the evils inflicted by the Spaniards on the Indians had their original in that fanaticism which he was desirous to bring into still deeper detestation. In these latter works he unluckily abandoned the simplicity which charmed so much in his *Moral Tales*, for a tone too highly rhetorical and turgid.

In 1763 Marmontel had been admitted, after considerable opposition, to the much-envied place of a member of the French Academy, and in 1783 he succeeded D'Alembert as its perpetual secretary. The situation of historiographer of France, and the chair of history in the Lyceum, which he successively obtained, fully indemnified him for the loss of the *Mercure*. He was in the full enjoyment of affluent circumstances, domestic felicity, and literary reputation, when the French Revolution suddenly changed the scene. During its alarming progress he led a retired life, and though reduced to indigent circumstances, remained secure amidst all the violent events of the period. In 1797 he was chosen a deputy to the National Assembly by the department of Eure, but he died soon afterwards, of an apoplectic attack, at his cottage near Abbeville, on the 31st December 1799.

After his death were published the *Nouveaux Contes Moraux*, 4 vols. 8vo, 1801; also a tolerable *Histoire de la Régence du Duc d'Orleans*, 2 vols. 8vo, 1805; besides his *Memoirs d'Une Pere, pour servir à l'Instruction de ses Enfants*, 4 vols. 8vo, 1804,—perhaps the most attractive and amusing of all his writings,—containing, however, among many agreeable and happy sketches, much paradox and self-contradiction; with a vast gallery of portraits of the most distinguished names of his time in France, ranging from Massillon to Mirabeau. Many of his pieces are of very doubtful morality.

MARMORA, Sea of, lies between European and Asiatic Turkey, between 40. 18. and 41. 5. N. Lat., 26. 40. and 30. 5. E. Long. It is 172 miles in length by 55 in breadth. At the east end it terminates in two long and narrow gulfs,—that of Izmid to the N., and that of Mudanieh to the S. It communicates with the Black Sea at the N.E. by the Bosporus or Straits of Constantinople, and with the Archipelago on the S.W. by the Dardanelles. The shores of the Sea of Marmora are beautiful in scenery and well cultivated; but those on the Asiatic side are bolder and more precipitous than those on the European. In some places the depth is very great; at a point 5 miles N. of Marmora Island no soundings have been obtained at 355 fathoms; and it is believed that in the centre the depth is very much greater. It is fed by several streams, of which the most important are the Karasu, Jatidji, and Chortu from Europe, and the Salataderé, Gweinimenshar, Mukhalitch, and Hyla from Asia. The navigation of the sea is safe, and not accompanied with much difficulty; and there are numerous good harbours on the northern shore and under the islands. This sea is not subject to tides; but a current runs through it from the Black Sea to the Mediterranean, varying in strength and swiftness at different seasons. The principal island, Marmora, which has given name to the sea, is celebrated for its marble quarries, from which in ancient times Cyzicus and other neighbouring cities, and in modern times Constantinople, have been supplied with building materials. The island of Marmora is occupied by a mountain range of no great height, and has a very barren appearance, although some wine is here produced. It is thinly inhabited, mostly by Greek Christians; and the town of Marmora, which stands on the S.W. coast, is chiefly built of wood. The island has a circumference of about 45 miles, and was anciently known by the names of *Proconnesus* or *Elaphonnesus*, on account probably of the deer with which it was then stocked. The other islands are,—Rabi, Liman-Pasha, Papa or Kalolimmo, and the group called Prince's Islands or Demonesi. The Sea of Marmora was called by the ancients *Propontis*, and was believed by them to lie due N. and S., so that the Dardanelles and the Bosphorus were placed on the same meridian.

MARMORICE, or Marmaras, a town of Anatolia, situated on the S.W. coast of Asia Minor, 27 miles N. of Rhodes. It is irregularly built, and the houses are mean; but it occupies a fine position at the head of a large bay. In the vicinity are the ruins of the ancient *Physeus*. The harbour is large and good, but the entrance is extremely narrow. The export trade is considerable in timber, honey, turpentine, wax, &c. At the mouth of the bay stands the cape of the same name. Lat. 36. 43. N., Long. 28. 20. E.

MARNE (anciently *Matrona*), a river of France, rising in the hills of Langres, and following a course nearly parallel to that of the Seine, flows first N.W. and then W., until it falls into that river a short distance above Paris, after a course of about 280 miles. The greater part of its course lies in the departments of Haute-Marne and Marne; but it also traverses those of Aisne, Seine-et-Marne, and Seine-et-Loire. It receives on the right the Ornain at Vitry, after a course of 48 miles; and on the left the Blaise, the Petit-Morin, and the Grand-Morin. The principal towns on the Marne are,—Langres, Chaumont, Joinville, Saint Dizier, Vitry-le-Français, Châlons, Mareuil, Epernay, Château-Thierry, Ferté-sous-Jouarre, and Meaux; and the river is navigable as far as Saint Dizier, 210 miles from its junction with the Seine. The Marne is joined to the Rhine by means of a canal, which follows for a considerable distance the course of the Ornain. It crosses the Meuse at Voide, the Moselle at Toul, and enters the Rhine at Strasbourg, its whole length being about 89 miles. Communicating with this canal another has been constructed from Vitry to Dizy, along the bank of the Marne, for 38 miles, on account of the rapid and winding character of this part of the river. There is also a third canal of 35 miles in length, which opens a communication between the Marne and the Aisne.

Marne, a department of France, situated between 48. 28. and 49. 23. N. Lat., 3. 25. and 5. E. Long., and bounded on the N. by the departments of Aisne and Ardennes, E. by those of Meuse and Haute-Marne, S. by that of Aube, and W. by those of Seine-et-Marne and Aisne. The department, which has an area of 3158 square miles, consists of a bare plain, sloping from E. to W., with a few scattered hills, which do not rise higher than 1200 feet. The soil consists of a thin layer of sand lying upon chalk, except in the W. and N.W. borders, and along the valley of the Marne, where the soil is rich and good. It is separated into two nearly equal parts by the River Marne, from which it takes its name; and is watered also by the

Aisne in the N.E.; by its tributaries the Suippe and the Vesle in the N. and N.W.; and by the Aube and the Seine in the S., the latter of which merely touches it for a very short distance. Marne enjoys a temperate climate and a pure atmosphere, although in the low and marshy tracts on the borders of the department fogs are very frequent. Cultivation is far advanced, and in a thriving condition. There are 500,000 acres of ploughed land, 193,000 of woods and forests, 189,000 of meadow land, 45,000 of vineyards, &c. Corn is grown to a considerable extent, especially oats and rye, which are more than sufficient for the supply of the wants of the department. Fruit trees are also numerous in Marne, and a great part of the department is covered with forests. But the most fruitful branch of agriculture in this district, and that on which most care is bestowed, is the cultivation of the vine, for Marne occupies a part of the old province of Champagne, so well known for the wines to which it has given name. This department produces annually about 15,400,000 gallons of wine. Many sheep are raised in Marne, and their breed has been much improved by crossing with the Merino and English breeds. The horned cattle and horses are small in size. Bees and domestic fowls are kept in great numbers in the department. The chief mineral productions are,—limestone, chalk, flint, millstones, building stone, clay of various sorts. The department is famous for the manufacture of woollen and other tissues, which centre chiefly at Rheims. The principal articles of trade are wines, together with corn, flour, brandy, hides, timber, and the produce of the manufactures. The department is crossed by the railway from Paris to Strasbourg, which enters Marne at Dormans, and leaves it at Sermaize, after a course of 68 miles. It is divided into five arrondissements, which, with their populations in 1851, are as follows:—

	Cantons.	Communes.	Population.
Châlons	5	109	52,562
Epernay	9	185	93,090
Rheims	10	183	138,031
Sainte-Menehould	3	82	36,246
Vitry-le-Français	5	135	53,373
Total	32	694	373,302

Marne, *Haute*, a department of France, bounded on the N. by the departments of Marne and Meuse, E. by that of Vosges, S. by those of Haute-Saône and Côte-d'Or, and W. by that of Aube, is situated between 47. 35. and 48. 40. N. Lat., 4. 38. and 5. 52. E. Long. The surface, which occupies an area of 2401 square miles, is for the most part hilly, and in some places mountainous. The southern part of Haute-Marne is traversed by the hills of Langres, rising to the height of 2500 feet, and the Faucilles Mountains,—the latter of which form part of a continuous chain between the Cevennes and the Vosges Mountains, and constitute the watershed between the Atlantic and the Mediterranean. The hills gradually diminish in height towards the north, where the country stretches out into beautiful valleys and extensive plains, broken here and there by hills either single or in groups. The geological character of the department is, with the exception of a single spot, of the secondary formation; and the prevailing structure is Jura limestone, with a small development of the coal measures. But notwithstanding the prevalence of mountains, and the small extent of rich soil in the department, it is well cultivated. Nearly a third of the surface is covered with forests. The principal rivers are the Marne, the Meuse, and the Aube, all of which have their sources in this department, which is also watered by several of their tributaries. The climate is healthy, and, though the cold in winter is intense among the mountains, the valleys and plains enjoy a mild and warm temperature. The amount of land producing corn in this department is 550,000 acres; vineyards, 37,500 acres; wood, 475,000 acres, &c. More corn is grown than suffices for the supply of the inhabitants: wine is also produced, but is not of great celebrity. Leguminous plants, hemp, &c., are cultivated; and a large quantity of wood is grown here for the supply of Paris. The sheep are numerous, and of a good breed, amounting to the number of 290,000; of cattle there are 90,000, not much esteemed; and of horses, 50,000. Poultry and bees are also reared; and many sorts of game abound in the department. Mining operations are carried on to a considerable extent in Haute-Marne; and the annual produce of the iron mines, for the working of which this is the first department in France, is valued at more than L.85,000. There are also quarries of good building stone, millstones, marble, &c. Iron manufacture is the chief branch of industry pursued here; and the cutlery of Langres and of Nogent is very famous. The other manufactures are,—gloves, stockings, paper, leather, beer, &c. The trade is chiefly in iron, wood, corn, wines, &c. Saint Dizier is the centre of the iron trade; and this town, along with Vitry and others, forms the principal emporium for wood. The capital of the department is Chaumont, and it is divided into three arrondissements, which, with their populations in 1851, are as follows:—

	Cantons.	Communes.	Population.
Chaumont	10	195	88,571
Langres	10	209	106,424
Vassy	8	145	73,403
Total	28	549	268,398

MARNOCH, a parish of Scotland, county of Banff, remarkable as having been the scene of one of the forced settlements which led to the disruption of the Church of Scotland in 1843, is situated on the Deveron, 9 miles S.W. of Banff; and has a population of 2994.

MARONITES, a tribe inhabiting the western declivity of Mount Libanus, figure in ecclesiastical history as a sect of Christians. By adopting the Monothelitic doctrine soon after it had been condemned in 680 by the council of Constantinople, they came to be considered a distinct religious party; and from having as their first bishop a certain monk, John Maro, they were called Maronites. Maro assumed the title of "Patriarch of Antioch," and asserted the ecclesiastical independence of the tribe. With no less intrepidity did the Maronites themselves, favoured by their native mountains, defend their freedom at first against the Greeks, and afterwards against the Saracens. At length, in 1182, they renounced the opinions of the Monothelites, and were readmitted within the pale of the Romish Church. Yet, as the terms of reconciliation were, that the religious tenets, moral precepts, and ancient rites of the country should remain unaltered, the Maronites adopted no popish opinion except the supremacy of the Roman pontiff. By this slight tie they still continue united to the Church of Rome. In return for their imperfect allegiance, the pope is obliged to defray the expenses of their public worship, and to maintain a college at Rome for the education of their priests. He has the power of sanctioning the appointment of their patriarch after he has been selected by their bishops. This dignitary resides in the monastery of Kanobin, assumes the title of Patriarch of Antioch, and by adopting the name of Peter, claims to be the successor of that apostle. Along with the bishops who compose his synod, he is bound to remain in perpetual celibacy; a law, however, which the rest of the clergy do not observe. The Maronite monks are of the Order of St Anthony, and live in convents scattered among the mountain solitudes.

Prompted no doubt by national vanity, so common among Syrians, Nairon and other Maronite doctors have essayed to prove that their tribe never entertained the Monothelitic heresy, and that it derived its name, not from John

Maro, but from Maro a monk of the fifth century. Both these statements, however, are disproved by the testimony of many unexceptionable authorities. (See Mosheim's *Ecclesiastical History*, Reid's edition.)

MAROS, or MAROSCH, a river in the Austrian empire, rises in Transylvania, in Mount Magos, a branch of the Carpathians, flows through Transylvania in a S.W. and W. direction, enters Hungary, and forms the northern boundary of the Banat, till it enters the Theiss opposite to Szegedin after a course of about 350 miles. During the earlier part of its course it is inclosed among high cliffs, but further down it flows through a wide plain. The country which it washes on either side is rich in minerals; gold and silver being found to the north, and iron, lead, and copper to the south. Its principal affluents are,—on the right side, the Aranyos; and on the left, the Nyarad, Kokel, Sebes, and Strehl. The most important towns on its banks are Arad, Karlsburg, and Szaaz; and it is navigable as far as Karlsburg.

MAROS-VASARHELY, or SZEKERLY-VASARHELY, a free town of Transylvania, capital of a circle of the same name, is situated near the Maros, 53 miles N.N.E. of Hermanstadt. The town is fortified, and occupies several small hills; the streets are wide, and the houses small, but for the most part well built. It is chiefly remarkable for its large and excellent public library of 80,000 volumes, which includes many fine editions of the ancient classics, and is kept in a handsome building. There are also here five churches, two convents, a Roman Catholic gymnasium and seminary, and a Protestant college. Maros-Vasarhely is also the seat of the Royal Table, the highest legal tribunal in Transylvania; and is in consequence a place of resort of large numbers of students and practitioners of law. In the neighbourhood is a garrisoned castle. Much tobacco is grown in the vicinity, in which the town carries on a considerable trade. Pop. 10,000.

MAROT, CLEMENT, the best French poet of his time, was born at Cahors in 1495, being the son of John Marot, valet-de-chambre to Francis I., and poet to Queen Anne of Bretagne. He enjoyed his father's place as valet-de-chambre to Francis I., and was page to Margaret of France, wife of the Duke of Alençon. In 1521 he followed that prince into Italy, and was wounded and taken prisoner at the battle of Pavia; but on his return to Paris he was accused of heresy and thrown into prison, where he wrote his *Enfer*, and revised the *Roman de la Rose*. Delivered by the protection of King Francis I., he at length retired to the court of the Queen of Navarre, then to that of the Duchess of Ferrara, and in 1536 returned to Paris; but having declared openly for the Calvinists, he was obliged to fly to Geneva, which he at length quitted for Lyons, where he renounced Calvinism; and after having taken part in the Italian campaign of 1535, under Francis I., he retired to Piedmont, and died at Turin in 1544, aged fifty. His verses are filled with natural beauties. La Fontaine acknowledged himself his disciple, and contributed greatly to restore to credit the works of this ancient poet. Marot, besides his other works, translated part of the Psalms into verse, a production which was condemned by the Sorbonne, but subsequently continued by Beza. *Michael Marot*, his son, was also the author of some verses; but they are not comparable to those of *John*, and much inferior to those of *Clement Marot*. The works of the three *Marots* were collected and printed together at the Hague in 1731, in 3 vols. 4to, and in 6 vols. 12mo.

MAROWINE, or MARONI, a river of South America, rises in the Serra Tumucucuraque, flows in a northerly direction, forming the boundary between French and Dutch Guiana, and falls into the Atlantic after a course of about 300 miles, in 5. 52. N. Lat., and 53. 50. W. Long. For about 15 miles up it is navigable for small boats; but the number of small islands, rocks, and quicksands that obstruct its course, prevent any vessel of large size from entering; and in the upper part of its course it is so much interrupted with rapids as to be totally unnavigable. It receives on the right the Rio Siburique and the Rio Waki, and on the left the Rio Tapahoni.

MARPURG, FRIEDRICH WILHELM, an eminent musical critic and writer on the theory and practice of music, was born at Seehausen, Brandenburg, in 1718. He received a good education, and early applied himself to the study of music. When about thirty years of age he was appointed to an office under government at Berlin, and from that time devoted his leisure to the writing and publishing of works on music. He published several editions of his work on the art of playing the harpsichord, and of his work on thorough-bass and composition; also several editions and a French translation of his work on fugue-writing, *Abhandlung von der Fuge*, &c.; which French translation was again published by Choron in his *Principes de Composition*, &c., 1808, and in his *Nouveau Manuel de Musique*, &c. It has been objected to Marpurg's work on fugue-writing, that he did not clearly understand the true principles of canonical imitation, nor of those most important parts of the fugue, the subject and the answer. Also, that the natural order of the objects treated of is quite inverted, double counterpoints being placed *after* fugue, and canons *after* double counterpoints. Choron rectified this confusion in his *Nouveau Manuel de Musique.* In 1758 Marpurg published a good work on the composition of vocal music, *Anleitung zur Singcomposition.* In 1763 appeared his introduction to music in general, *Anleitung zur Musik überhaupt*, &c. In 1757–74–76–79 he published four works on theoretical music and on temperament. Besides these, he published several critical and historical works relative to music, and some of his own musical compositions. He also edited two collections of pieces for the harpsichord, and a collection of fugues by celebrated German composers. He died at Berlin on 22d May 1795. (G. F. G.)

MARQUESAS, or MENDAÑA ISLANDS, a group of islands in the South Pacific Ocean, situated between 8. and 11. S. Lat., and 138. 30. and 143. W. Long. The number of the islands is twelve; and they extend to a length of 200 miles from N.W. to S.E.; being divided into two smaller groups, one lying to the N., and another to the S. The principal islands in the southern group are,—Santa Dominica or Hiwaoa, Santa Christina or Tahuata, San Pedro or Motane, and Hood's Island or Tiboa, of which the average length is about 10 miles. Of the northern group, the largest is Noukahivah, 20 miles in length and 70 in circumference; and the other principle ones are,—Uahuga or Washington Island, Uapoa or Adam's Island, Motouiti or Franklin Island, and Ohivaoa. These islands present a mountainous and rugged appearance; their coasts, which are bold and precipitous, being unprotected by any coral reefs, are exposed to the sea, which beats on them with violence; and the centre of each island is occupied by a ridge of rocky mountains, rising in the larger islands to the height of 2000 or 3000 feet. From these mountains branches stretch out, reaching down to the sea, and dividing the surface of the islands into numerous small valleys. The soil in these parts is rich, consisting of clay mixed with vegetable remains; but on the higher grounds it is thin, and produces only a coarse sort of grass. Considerable portions of the islands are covered with forests of cocoa-nut, bread-fruit, papaw, and other trees. The natural productions of this group closely resemble those of the Society Islands; but the fan palm, which is unknown in these islands, is found in the Marquesas. Cultivation is practised to a considerable extent; the principle articles of produce being cotton, sugar, tobacco, potatoes, bananas, and plantains. The inhabitants supply vessels with vegetables and live stock, in return for which they obtain muskets and ammunition for their own use and that of the neighbouring islands. The climate is warm, and the thermometer generally ranges between 64° and 80°. Abundant showers of rain fall in winter, but thunder-storms seldom take place; and sometimes for a period of ten months the islands are without rain—an event which invariably produces a famine. The trade wind from the E. blows frequently here, especially in autumn; but winds from the N. in summer, and from the N.W. in winter are very common. The inhabitants are of a copper colour, are remarkable for the symmetry of their limbs, and though not tall, their appearance is strong and healthy. While the inhabitants of each valley are governed by a single independent chief, yet the possessor of Resolution Bay, one of the best and most frequented harbours, by means of his traffic with Europeans, has acquired considerable influence over the neighbouring princes. This chief took under his protection two English missionaries, who settled here in 1835. The open practice of idolatry has been given up, yet the people still retain many of the manners and superstitions of paganism. They are, however, generally honest and well disposed to Europeans; and the ideas formerly entertained of their cruelty and cannibalism have been found by later visitors to be unfounded. These islands were first visited in 1596 by Mendaña, who discovered four of the southern group, and called them *Marquesas de Mendoza*, after Don Garcia de Mendoza, then viceroy of Peru. Hood's Island was discovered by Cook in 1776, and the others by the Americans in 1797. In 1842 these islands came under the protection of France. Pop. estimated at 20,000.

MARQUIS, or Marquess, a title of honour next in dignity to that of duke. The office of marquis is to guard the frontiers and limits of the kingdom, which were called the *marches*, from the Teutonic word *marche*, a limit, as, in particular, were the marches of Wales and Scotland whilst they continued hostile to England. The persons who had command there were called *lords marchers* or *marquesses*, whose authority was abolished by statute (27 Hen. VIII., c. 27), though the title had long before been made a mere design of honour. The first English marquis was Robert de Vere, Earl of Oxford, created Marquis of Dublin in 1385 by Richard II. This title was first known in Scotland in 1599, when the Marquises of Huntly and Hamilton were created. Since the Revolution, this title has been given as a second title on conferring a dukedom. A marquis is created by patent; his mantle is double ermine, three doublings and a half; his title is *most noble*; and his coronet has pearls and strawberry leaves intermixed round, of equal height.

MARRACCI, Ludovico, a learned Italian, who was born at Lucca in Tuscany in 1612. He applied himself principally to the study of languages, especially Greek, Hebrew, Syriac, Chaldee, and Arabic, which last he taught for some time at Rome. Pope Innocent XI. chose him as his confessor, placed great confidence in him, and would have advanced him to ecclesiastical dignities if Marracci had not opposed it. Marracci died at Rome in 1700, aged eighty-seven. The great work upon which his reputation chiefly rests is his edition of the Koran in the original Arabic, with a Latin version under the title of *Alcorani Textus universus ex correctioribus Arabum exemplaribus summa fide atque pulcherrimis characteribus descriptus*, Padua, 1698, in 2 vols. folio; the first contains the *Prodromus*, and the second the Koran, with critical and grammatical notes, which are highly esteemed. The version of the Koran by Marracci, with notes and observations by himself and others, and a synopsis of Mohammedan religion, by way of introduction, was published by Heineccius at Leipzig, 1721, in 8vo. Marracci had also a hand in the *Biblia Sacra Arabica Sacræ Congregationis de Propaganda Fide jussu edita, ad usum Ecclesiarum Orientalium*, Rome, 1671, in 3 vols. folio.

MARRAST, Armand, a French journalist, and one of the chief authors of the republican constitution of 1848, was born in the south of France in 1802. His career as a political writer began at Paris in 1827, and he soon became distinguished as a defender of the practical school of philosophy as opposed to the eclecticism of Cousin. In 1830 he established the newspaper *La Tribune*, which during several years was the acknowledged organ of the ultra-Liberals. For some fierce invectives in this periodical against the government Marrast was at different times prosecuted; and for a pamphlet entitled *Vingt Jours de Secret* he was compelled to flee to England. In 1836, when Carrel was slain in a duel, Marrast succeeded him as chief editor of *Le National*, and speedily converted that organ of moderate and philosophical Republicanism into a vehicle of vigorous but scurrilous tirade. By his bold and persistent attacks upon the government and the court, he was a chief instrument in accelerating the Revolution of 1848. Accordingly, he acted a prominent part in the new government, became president of the National Assembly, and was re-elected to the same office at the end of several successive months. As rapid, however, in his fall as in his rise, Marrast was soon forced to flee from the vengeance of the Red Republicans, and living in retirement, he was almost forgotten, when his death, in March 1852, introduced his name once more to the public.

MARRIAGE. See Husband and Wife.

MARRUCINI, a people of Central Italy, inhabited a narrow strip of land extending along the banks of the River Aternus (*Pescara*), from the Adriatic to the Apennines, and bounded on the S. by the territory of the Frentani. Their country, on account of its eastern exposure, was more fertile than the neighbouring districts. Teate (*Chieti*), situated on the Aternus, was their most important city. The Marrucini were of Sabine origin. They were an independent people, although they almost invariably appear in history as allies of the neighbouring tribes of the Marsi and Peligni. Along with these they became confederates of the Romans in 304 B.C., and revolted at the commencement of the Social War. Their district was included in the Fourth Region of Augustus.

MARRYAT, Frederick, *Captain*, R.N., C.B. and F.R.S., was born in London, on the 10th of January, 1792. He was the second son of Joseph Marryat, Esq. of Wimbledon House, Surrey, M.P. for Sandwich, a considerable West India merchant, and chairman of Lloyd's, who traced his descent from a family of French refugees. He was educated in London, and entered the navy in 1806 as midshipman on board the "Impérieuse," a frigate of 44 guns, commanded by Lord Cochrane, under whom he served till 18th October 1809, taking gallant part in the daring exploits of that celebrated officer. During this time he was in nearly fifty engagements of more or less importance, in the Mediterranean and on the coast of France. Once, in boarding a vessel in the bay of Arcupon, he was knocked down by the fall of the officer in command, close behind whom he was entering, trampled upon in the rush of his own party, and left for dead. In 1808 and 1809 he took part in the reduction of the castle of Mongat, the defence of the castle of Trinidad, and the attack on the French fleet in Basque Roads. For the gallantry and ability displayed in these dangerous services, he received honourable mention in Lord Cochrane's despatches. Four times he jumped overboard to rescue shipmates, on one of which occasions he narrowly escaped being devoured by a shark; and once his skill and intrepidity saved his ship. He was lieutenant in 1812, and appointed to "L'Espiègle," in the West

Indies, whence he removed, in January 1814, to the "Newcastle," 58 guns, Captain Lord George Stuart, which was despatched to the American coast, and cut out four vessels at New Orleans. In 1815 he acquired the rank of commander, had the "Beacon" sloop off St Helena, then the "Rosario," 18 guns, in which he brought home despatches announcing the death of Napoleon. After being some time employed in the preventive service, in which he effected thirteen seizures, he was appointed to the "Larne," 18 guns, in March 1823, and sailed to the East Indies, where, till 1825, he was fully employed as senior officer of the naval forces. He led the attack on Rangoon in 1824, and was twice thanked by the governor-general of India for his services in the Burmese war. He was also warmly recommended by Sir Archibald Campbell, the commander-in-chief, from whom he received three letters of thanks. In February 1825 he accompanied Sir Robert Sale in the successful expedition to reduce the territory of Bassein, and returning in April, was promoted to the command of the "Tees," which he brought home to England. In June 1825 he received the decoration of C.B., and a medal from the Humane Society for saving so many lives. From November 1828 to November 1830, he commanded the "Ariadne" in the Channel service. It was at this time, in 1829, that he began his literary career; encouraged by the reception of his *Frank Mildmay*, he produced in rapid succession his well-known novels,—*The King's Own*, *Peter Simple*, *Jacob Faithful*, *Japhet in Search of a Father*, *Newton Forster*, *Midshipman Easy*, *The Pacha of many Tales*, *The Poacher*, *The Phantom Ship*, *Snarly Yow*, *Olla Podrida*, *Poor Jack*, *Masterman Ready*, *Percival Keene*, *Monsieur Violet*, *Settlers in Canada*, *The Mission*, *The Privateersman*, *Valérie*. The most of these are sea-novels, of very unequal merit, but all lively, and abounding in adventure. His descriptions of any other life than life on board ship, and any other characters than sailors, are not brilliant nor accurate, though always lively and spirited; but in his own walk he is unrivalled, and in this his best works are perhaps *Peter Simple* and *Poor Jack*. His *Code of Signals for the use of Vessels employed in the Merchant Service*, published in 1837, was adopted by our government, and is now in general use by our own and foreign navies. For this service he twice received the thanks of the Shipowners' Society; and the work being translated into French in 1840, and adopted, he received from Louis Philippe the gold cross of the Legion of Honour. His *Diary in America*, published in 1839, in two series of three volumes each, is an amusing and clever production, written, however, with little aim beyond amusement, and full of satirical exaggeration. It gave great offence in the United States. He died on the 2d of August 1848, at Langham in Norfolk, after having for a year or two been obliged to desist from all literary and professional exertion by the bursting of several blood-vessels. By his marriage with Catharine, daughter of Sir Stephen Shairp, formerly *chargé d'affaires* at St Petersburg, he had six children. His eldest son, a lieutenant in the navy, perished in 1847 in the "Avenger" steamer, on the coast of Africa. (W. H. C.)

MARS, the Roman god of war, was originally called *Mavors* or *Mavers*, and was identical with the Sabine and Oscan deity Mamers. Among the Romans he came gradually to be viewed in three different characters, and to receive different names corresponding to these characters. He appears to have been regarded originally as the father of Romulus, and accordingly was considered one of the tutelary divinities of Rome. In this character he was called *Quirinus*, a name derived from the Quirinal Hill, on which his ancient temple stood. But, as the founder and patron of Rome, Mars was naturally supposed to preside over agriculture, the favourite calling of the primitive Romans. He was therefore worshipped as a rustic deity, under the title of *Silvanus*. Another honourable vocation, however, in ancient Rome was the art of warfare. For the same reason, therefore, that Mars was held to be the god of agriculture was he supposed to be the god of war. In this last character he was worshipped under the name of *Gradivus* by priests called Salii. Mars was generally painted as an armed warrior of a fierce aspect, riding in a chariot, and brandishing a spear. His shield (*ancile*) is said to have fallen from heaven in the reign of Numa, and was carefully preserved as the symbol of the perpetuity of the Roman power. To lessen the chances of its being stolen, it was placed among eleven other shields exactly like it. At the ancient temple of Mars, near Reate (*Rieti*), the responses of the god were communicated by the mouth of his sacred bird the woodpecker (*picus*). He was also worshipped with great honours at Tuder (*Todi*), in a sanctuary still seen in ruins. Of the numerous temples dedicated to him at Rome, the most famous was that of Mars Ultor, built by Augustus in the Forum Augusti. The quadrupeds sacred to Mars and most acceptable to him in sacrifice, were the horse and the wolf. The name of his wife was said to be Nerio or Neriene. At an early period he was identified with the Greek god Ares. The month of March and the Campus Martius were named after Mars.

MARSAIS, CESAR CHESNEAU DU. See DUMARSAIS.

MARSALA (the ancient *Lilybœum*), a seaport of Sicily, in the province of Trapani, is situated on the low promontory of Cape Boeo, on the W. of the island, 18 miles S.S.W. of Trapani. The town is of a square form, and surrounded by old fortifications, which, though at present neglected, might easily be rendered capable of defence. The ancient harbour was good, but is now filled up, and the present one is about a mile S. of the town. Marsala is traversed by a straight and broad street, called the Cassaro, in which stands a large cathedral, with sixteen handsome Corinthian columns of marble. The town has sixteen other churches, many convents, three abbeys, a gymnasium, seminary, hospital, &c. Among the curiosities of the place may be mentioned an old castle, a church with a tower which perceptibly vibrates by the ringing of the bell, and a few remains of aqueducts and tombs of ancient date. The harbour was so highly esteemed by the Saracens as to have received from them the name of *Marsa Alla* (the Harbour of God). In modern times Marsala derives its chief importance from its trade in the wine grown in the neighbourhood, which is much prized. The quantity produced in the neighbourhood is calculated to amount to 30,000 pipes, of which about two-thirds are exported principally to England, the United States, and the West Indies. Small quantities of corn, cattle, oil, &c., are also exported from Marsala. Pop. about 21,000.

MARSDEN, WILLIAM, an eminent oriental scholar, was the son of a merchant in Dublin, and was born in 1754. After studying at Trinity College in that city, he obtained an appointment in the civil service of the East India Company, and set sail for Bencoolen, Sumatra, in 1771. There he soon rose to the office of principal secretary to the government, and was at the same time intent on acquiring that intimacy with the Malay language, and that knowledge of the country, which were afterwards the sources of his literary reputation. Returning to England in 1779 with a pension, he retired into literary seclusion; and in 1782 produced *The History of Sumatra*. Marsden was appointed in 1795 second secretary, and in course of time first secretary, to the Admiralty. In 1807 he retired again into private life, and devoting himself to study, published in 1812 his *Grammar* and *Dictionary* of the Malay language, and in 1817 his translation of the *Travels of Marco Polo*. A pension of L.1500, which he had received on his retirement from office, he voluntarily resigned in 1831 for the behoof of the public. In 1834 he presented his rich collection of oriental coins to the British Museum, and his library of books and oriental MSS. to King's College. He died of apoplexy in October 1836. Marsden's other works are,—*Numismata Orientalia* (Eastern Coins), 4to, London, 1823–25; *Catalogue of Dictionaries, Vocabularies, Grammars, and Alphabets*, 4to, London, 1796; and several papers touching the language, manners, and antiquities of the East, in the *Philosophical Transactions* and the *Archæologia*.

MARSEILLE, a town of France, capital of the department of Bouches-du-Rhone, is situated on the Mediterranean, 30 miles W.N.W. of Toulon, and 475 S.S.E. of Paris. This city was founded about the year 600 B.C. by a colony of Greeks from Phocæa in Ionia, and was called by them *Massalia*, which was afterwards changed by the Romans into *Massilia*, from whence was derived its modern name. (See MASSILIA.)

After the fall of the Roman Empire, Marseille was at different times under the power of the Visigoths, Ostrogoths, and Franks. In the year 720 the greater part of the town was taken and sacked by the Saracens; but the upper city held out until Charles Martel and his brother Childebrand came to the rescue and expelled the Saracens. After this period Marseille continued to increase in wealth and prosperity, though much harassed and threatened by pirates, especially during the reign of Louis le Débonnaire in the ninth century. Up to the time of William I., Viscount of Marseille, this city had preserved a republican form of government; but under that prince and his successors, till the twelfth century, the government was monarchical, though this change exercised no adverse influence on the progress of the arts, industry, and commerce of Marseille. For some time after the restoration of the republican constitution, Marseille formed one of a confederacy of similar small states, including those of Arles, Grasse, &c., and after a struggle for six years against the Counts of Provence, was finally obliged, in 1243, to recognise their authority. Soon afterwards, however, Marseille was involved in a war with Charles of Anjou, brother of Louis IX., which ended in its falling into the hands of that prince. Under the House of Anjou, Marseille continued until the year 1482, when Charles du Maine, the heir of the line of Anjou, bequeathed Marseille to Louis XI., with a stipulation that the time-honoured liberties of the city should be respected. In the year 1524 Marseille was besieged by the imperialists under the Constable de Bourbon, but the inhabitants made a desperate resistance, and succeeded in repelling their adversaries. Marseille was made by Louis XIII. a station of the French navy, and provided with a dockyard and arsenal; and the good effects of this were seen in the clearing the Mediterranean of the pirates which infested it. In the reign of Louis XIV. a sedition broke out here, of which the ringleader was Noiselles; but the "Great Monarch" having made his appearance in 1660, quelled the sedition, and deprived the city of its peculiar privileges, erecting at the same time the citadel of St Nicolas. In 1720 and 1721 Marseille suffered from a fearful visitation of the plague, which, although it had frequently made its appearance previously, had never been so destructive as on this occasion, when it carried off between 50,000 and 60,000 victims. Marseille hailed with joy the beginning of the first French Revolution, but the event did not correspond to the hopes entertained at the outset, and the commerce of Marseille was almost ruined in the commotions of that unhappy period. After the Restoration, however, the city recovered its former commercial importance, and is now daily increasing in wealth and magnificence.

The situation of Marseille is not only very convenient for commerce and navigation, but is extremely beautiful and picturesque. It is built on the slope of the hills which surround the excellent harbour in a semicircular form. The town consists of two distinct parts, an old and a new; the former, which occupies the site of the ancient *Massilia*, is situated on uneven ground to the N. of the harbour, and is irregularly and ill built, with narrow and dirty streets. The new town, on the other hand, consists of broad and straight streets, as well as splendid and elegant squares, which rival in magnificence those of Paris. The division between the old and new town is marked by a public promenade called the "Cours," lined with trees, and adorned with numerous fountains, and which, along with the streets of Aix and Rome, forms a thoroughfare extending in a straight line through the city, from the triumphal arch at the northern extremity, to an obelisk which stands near the gate by which the road from Rome enters Marseille. Another favourite promenade is the Rue de la Cannebière, a broad street extending from the Cours to the harbour, and commanding a view of the shipping. The walls which formerly inclosed Marseille have been converted into boulevards; and beyond these the town has extended, and is still rapidly extending itself, in all directions. On a hill to the S. stands the fort of Notre Dame de la Garde; and the entrance of the harbour, formerly closed during the night by a chain, and hence called "La Chaine," is protected by the Fort St Jean on the N., and St Nicolas on the S. The approach is still further guarded by the fortified island of If, which has long served as a state prison, as well as by the islands of Pomegue and Ratoneau, which are also fortified. The harbour of Marseille, which was in ancient times called *Lacydon*, is of a rectangular shape, and is about 1020 yards in length by 327 in breadth. It is secure and convenient, and surrounded by a number of excellent quays, which are always thronged with a busy crowd of men of all nations. Although the harbour can accommodate 1200 vessels, it has been found insufficient for the numbers of those frequenting it, and a new harbour has been accordingly constructed, called La Joliette, opposite to Fort St Nicolas. The neighbourhood of Marseille is extremely dry and barren; and although there are numerous *bastides* or country houses in the vicinity, the only attraction which these possess is the view of the sea, to which Marseille owes not only its wealth, but a great part of its beauty. The public buildings of Marseille are not so numerous as might be expected; and the view of the city from an eminence is remarkably destitute of spires, domes, and other indications of large and handsome buildings. The cathedral, which is called the "Major," or the church of St Victor, is of very great antiquity, but is by no means an elegant or imposing structure, and its castellated towers give it the appearance rather of a fortress than of a place of worship.

The Hôtel de Ville stands on the northern side of the harbour, and is a rather heavy building, said to be the work of the celebrated Puget, but which was in all probability executed by some inferior hand. One of the finest buildings in Marseille is the Hôtel de la Prefecture. The only others that deserve notice are the new market-house, the theatre, resembling the Odeon at Paris, and the Palais de Justice. In the neighbourhood is the chapel of Notre Dame de la Garde, which contains an ancient olive-wood statue of the Virgin, held in the highest veneration by sailors and fishermen, and a modern one of silver; besides many votive pictures. The church of St Madeleine, also in the suburbs, is an elegant building, and has two light steeples and a fine front. The town contains altogether about twenty Roman Catholic churches, two Greek ones, one Protestant church, and a synagogue. There is a museum and picture gallery, in the former of which are to be seen a few remains of the ancient city of Massilia, which are not of much interest, and do not ascend to a higher antiquity than the time of Julius Cæsar. The number of pictures in the gallery is about 150, and some of them are very good, though they are not hung in a favourable light. The public library of Marseille consists of about 80,000 printed volumes and 1300 MSS. Marseille has a royal college, occupying a building which was formerly a Bernardine convent, and attended by 300 or 400 students; a royal society of science, literature, and art; an observatory, with schools of navigation, geometry, &c., a good museum of natural history, and a botanic garden. There are at Marseille numerous charitable institutions. The Hôtel Dieu, founded in 1188, is one of the oldest hospitals in France, and is capable of accommodating 750 patients. The Hôpital de la Charité, for the aged, orphans, &c., contains generally from 600 to 680 persons. Situated to the N. of the city is the lazaretto, one of the most perfect establishments of the sort in Europe. This institution is rendered necessary by the frequency with which Marseille has been visited by the plague. The town also possesses public baths. There are published at Marseille three newspapers and several literary journals. The city has a tribunal of primary instance and one of commerce, a chamber of commerce, a council of *prud'hommes*, a *syndicat maritime*, and an *hôtel des monnaies*. Although Marseille is not famous for its manufactures, yet its industry in this department is considerable, and there are many important manufacturing establishments. In former times Marseille was much celebrated for the manufacture of coral into various articles; but this has of late much fallen off, and is now carried on to a greater extent at Genoa, Leghorn, and Naples. Soap-making is largely carried on, and affords employment to about 700 hands. Next in extent to the soap-works of Marseille are the refineries of sugar, sulphur, wax, and borax; the manufactures of steam-engines and machinery; the tanneries, which, however, have rather fallen off of late; the manufacture of hats, of which there are produced from 40,000 to 65,000 annually; the making of china, glass, bricks, &c. The Marseillais are also employed to a considerable extent in the salting of meat and fish, and in the pickling and preserving of various sorts of fruits. The fish and the flower markets are in general well stocked, and present a very animated appearance. An aqueduct has been recently constructed, with great labour and expense, for conveying the water of the Durance to the town. This gigantic work, one of the greatest of its kind in modern times, is remarkable for the bold and skilful engineering with which it has been executed; it is about 60 miles in length, and is carried through 15 miles of tunnels. Marseille, however, is chiefly remarkable as a commercial city, in which respect it is second to none in France, being the great emporium for all the southern parts of the kingdom. Its position is in many respects most favourable for trade, being situated on the shores of the Mediterranean, and having Spain on the right, Italy on the left, and Africa in front; while at the same time it communicates with the centre of France by the large and navigable River Rhone. The exports include all sorts of articles of home produce, such as silk, linen, and woollen stuffs; wines, brandies, &c.; oil, soap, refined sugar, perfumery, stationery, and gloves. Among the imports may be noticed sugar, coffee, &c., from the colonies; corn from Africa and the Black Sea; manufactured goods from England; cotton, hides, wool, tallow, timber, &c. The great advance of Marseille in trade dates from the French conquest of Algiers in 1830, since which time this town has had almost a monopoly of the trade with that country. It is also the chief station for the steam-packets on the line of communication with Malta, Alexandria, and Constantinople. The number of vessels belonging to the port in 1851 was 804, the tonnage 92,237; and in 1855 the number was 913, and the tonnage 130,860. The number of vessels that entered in that year was 5016; that left, 4433; and in 1856 the aggregate number entered and left was 10,183. The total value of the articles imported in 1853 has been computed to amount to L.8,000,000; and the exports are believed to be about equal in value. In 1855 the value of the imports was above L.11,000,000. The quantity of duties collected at Marseille in 1851 was L.1,227,000, being greater than the amount collected at any other port of France. The people of Marseille still preserve many traits of the ancient Greek character, and are noted for their superstitious observance of rites and ceremonies. This may be remarked in the votive offerings with which the chapels are hung round, and in the numerous religious processions, in which the gaiety as well as the superstition of the people find expression.

The Marseillais do not regard themselves as of the same country with the rest of the French, and manifest the same contempt for strangers that was characteristic of the ancient nations. The dialect which is spoken by the greater part of the inhabitants of Marseille is Provençal, which is made up of a mixture of Greek, Latin, Catalan, and French, with a great number of words whose origin can be traced to none of these languages. Marseille is distinguished as having given birth to many famous personages; among whom, in ancient times, the most illustrious was Pytheas the navigator: and in modern times, Puget the artist and architect, born in 1622; Mascaron the preacher, born in 1634; and Peysonnel the antiquary, born in 1700,—may be noticed. Pop. (1851) 185,082.

MARSH, Dr Herbert, Bishop of Peterborough, was born in London in 1757. After receiving his education and gaining a fellowship at St John's College, Cambridge, he removed to Germany in 1783, and resided for several years at Göttingen. In a short time he had become sufficiently intimate with the language of that country to publish several German tracts in defence of the policy of Great Britain touching the continental wars. So successful were these pamphlets in effecting the purpose at which they aimed, that Marsh, on the recommendation of Mr Pitt, was rewarded with a pension, and was now started on the open road to preferment. On the invasion of Germany by the French he returned to England. Created D.D. by royal mandate in 1806, Marsh was appointed in 1807 Lady Margaret's professor of divinity at Cambridge. In teaching from this chair he abandoned the custom of lecturing in Latin followed by his predecessors, and lectured only in English. He was promoted to the see of Llandaff in 1816, but was translated to that of Peterborough in 1819. He died in 1839. Varied as well as profound, the learning of Bishop Marsh comprised an intimacy with theology, politics, and Greek, Latin, German, and oriental literature. He was the first who imported into this country the biblical criticism of Germany. In defence of his own church, he was an uncompromising foe of Calvinism on the one hand and Popery on the other. His translation of *Michaelis's Introduction to the New Testament* was reckoned a work of great value.

The chief of his other works are,—*The Authenticity of the Five Books of Moses considered*, 4to, Cambridge, 1792; *The History of the Politics of Great Britain and France, from the time of the Conference at Pilnitz to the Declaration of War against Great Britain*, 2 vols, 8vo, London, 1800; *Lectures on the Criticism and Interpretation of the Bible, with two Preliminary Lectures on Theological Study and Theological Arrangement*, 8vo, London, 1838; *Lectures on the Authenticity and Credibility of the New Testament, and on the Authority of the Old Testament*, a new edition, 8vo, London, 1840; and *The National Religion the Foundation of National Education*, 8vo, London, 1811.

MARSHAL, or Mareschal (*marescallus*), primarily denotes an officer who had the charge or the command of horses, and from the importance of such an office, ultimately became invested with great military authority. The title of Marshal of England, formerly passed by grant from the king, has been hereditary in the family of the Dukes of Norfolk since 1672. The earliest marshals on record are those of William the Conqueror, viz., William Fitz-Osborne and Roger de Montgomery. The earl marshal holds the eighth rank among the great officers of state in England, and exercises the same authority over the Court of Chivalry which the constable and marshal together formerly possessed. In Scotland the office of earl marshal has never been out of the family of Keith. The *Marshal of the King's Household* hears and determines pleas of the Crown; and the *Marshal of the King's Bench* has the custody of the King's Bench Prison, Southwark, or of the *Marshalsea*, as it is thence called. The *Marshal of France* is the highest military rank in the French army, as that of *Field-Marshal* is in our own.

MARSHAM, Sir John, a learned chronologist, the son of an alderman of London, was born in that city in 1602. From Westminster School he passed in 1619 to St John's College, Oxford, where he was chosen Master of Arts in 1625. During the two following years he travelled in France, Italy, and Germany, and then repaired to London to study common law in the Middle Temple. In 1629 he went to Paris in the suite of Sir Thomas Edmunds, ambassador extraordinary. His studies, thus interrupted, were resumed on his return; and in 1637 he was appointed one of the six clerks of Chancery. Adhering to the cause of the royalists during the civil war, Marsham was deprived of his office and of part of his estate, and on the complete defeat of his party, was fain to compound for the remnant of his property, and to devote himself to literature. He was member for Rochester in the Parliament that recalled Charles II.; and immediately after the Restoration in 1660 he was restored to his clerkship in Chancery, and was created a knight. Three years afterwards a baronetcy was added to his honours. He died at Bushy Hall, Hertfordshire, in May 1685. Sir John Marsham was an eminent scholar in languages, history, and chronology. His works were, *Diatriba Chronologica*, 4to, London, 1649; and *Chronicus Canon Ægyptiacus Hebraicus et Græcus*, folio, London, 1672, Leipsic, 1676, and Franeker, 1696. The former is an attempt to elucidate the chronology of the Old Testament; the latter, besides comprising a great part of the former, has an ingenious disquisition on the Egyptian dynasties.

MARSHFIELD, a market-town of England, county of Gloucester, 13 miles E. of Bristol. The principal street is about a mile long; and the town consists chiefly of old buildings. There is a parish church, places of worship for Independents and Unitarians, an endowed school, and several alms-houses. A considerable trade is carried on in malt. The market-day is Tuesday; and there are two annual fairs. Pop. 1648.

MARSHMAN, Joshua, D.D., an eminent missionary, was born at Westbury Leigh in Wiltshire in 1767, and was sent to the East Indies in 1799 by the Baptist Missionary Society, to join the Serampore Brethren, as Dr Carey and his colleagues were styled. On reaching the sphere of his labours, Marshman, in addition to his more special duties, engaged in the study of the Bengalee, Sanscrit, and Chinese languages, which, after great perseverance, he succeeded in mastering. He afterwards translated into Chinese the book of Genesis, the four Gospels, and the Epistles of Paul to the Romans and the Corinthians. In 1809 he published a *Dissertation on the Characters and Sounds of the Chinese Language;* in 1811 he produced *The Works of Confucius, containing the Original Text, with a Translation;* and in 1814 appeared his *Clavis Sinica*. He also wrote *Elements of Chinese Grammar, with a Preliminary Dissertation on the Characters and Colloquial Medium of the Chinese;*—all printed at Serampore. As the result of his Sanscrit and Bengalee studies, he engaged with Dr Carey in 1815 in writing a Sanscrit grammar, and in 1825 a Bengalee and English dictionary. Owing to some painful misunderstanding which arose between the Serampore Brethren and the committee of the Baptist Missionary Society in 1815, and which resulted in their acting for some time as separate bodies, Dr Marshman was induced in 1826 to visit England, where the causes of difference were subjected to strict scrutiny. The famous John Foster, with whom Dr Marshman resided, shook off his langour for a time in order to get to the bottom of this matter; and after the most ample opportunity of acquainting himself with all the circumstances of the case, and while admitting that Marshman's conduct was regulated too much on the principle of silent pertinacity and cautious "management," he nevertheless unhesitatingly alleged, "I believe there is not in Christendom a man more highly and uniformly conscientious, a man more anxiously and scrupulously solicitous to do right in all things." He returned to Serampore in 1829, but did not enjoy the satisfaction of witnessing the re-union of the mission there with the parent society, concluded in London a few days before his death, which took place on the 5th of December 1837. After the conversion of Rammohun Roy to Christianity, Dr Marshman replied to a work of the rajah's assailing the miracles of Christ, entitled *The Precepts of Jesus the Guide to Peace*, in a series of articles in the *Friend of India*, subsequently collected and published under the title of *A Defence of the Deity and Atonement of Jesus Christ, in Reply to Rammohun Roy of Calcutta*, London, 1822; to which the rajah published a reply in the second London edition of his book in 1824.

MARSI, an ancient tribe of Central Italy, inhabited the district around the Lake Fucinus (*Lago di Celano*). They were of Sabine origin, and accordingly they were closely related by descent, as well as by common political interests, with their neighbours, the Vestini, the Peligni, and the Marrucini. Indeed, their name seems to indicate that they were the parent stock of the last tribe. Their only important town was *Marrubium*, still seen in ruins on the E. shore of Lago di Celano. At what period the Marsians became allies of the Romans is unknown; but we find that they revolted in 308 B.C., and leagued themselves with the Samnites. After they had been subdued, they again, in 301 B.C., shook off the alliance of Rome, and not until they had ceded part of their territory could they conciliate their former ally. From this period they continued to fight submissively under the Roman banners, until the Italians demanded in 91 B.C. a share in the privileges of the citizens of Rome. The Marsians then took so prominent a position among the malcontents, that the struggle which ensued, though generally known as the Social War, was frequently styled the Marsic War. When a series of defeats, or the concessions of their enemies, had won the rest of the allies to submission, the Marsians kept the field alone, and although they were often defeated, only laid down their arms in 87 B.C., when they had attained the object for which they had taken them up. Thus they became amalgamated with the other Italian tribes, and lost their national individuality.

Inhabiting a mountainous district, the Marsians were simple and temperate in their habits, but hardy, brave, and stubborn in action. So marked was their valour, that at one time there was a current saying that Rome had achieved no triumph *over* the Marsi or *without* the Marsi. The ancient Marsians were noted for their ability to tame serpents and to heal their bites; and it is rather remarkable that the jugglers who at present amuse the populace of Rome and Naples by handling these reptiles, are natives of the vicinity of the Lago di Celano.

MARSIGLI, Luigi Ferdinando, Count, an Italian geographer and naturalist, was descended of an ancient and noble family, and born at Bologna on the 10th of July 1658. He studied under Borelli and Malpighi, and acquired an extensive knowledge of the art of war and of fortification. He subsequently served under the Emperor Leopold II. against the Turks, by whom he was taken prisoner in 1683, but ransomed after a year's captivity. In the war of the Spanish succession, Marsigli, then advanced to the rank of marshal, being in the fortress of Brisack, which surrendered to the Duke of Burgundy in 1703, when the place was deemed capable of holding out much longer, was stripped of all his commissions, and had his sword broken over him. Marsigli now turned his attention exclusively to science, in which he had made great progress during his military career. In 1712 he presented the senate of Bologna with his astronomical and chemical instruments and apparatus, his plans of fortifications, models of machinery, &c., laying thereby the foundation of the Institute of the Arts and Sciences of Bologna. He also established a printing-house, furnished it with the best types for Latin, Greek, Hebrew, and Arabic; and in 1728 presented it to the Dominicans at Bologna, upon condition of their printing all the writings of the Institute at prime cost. This was called the Printing-House of St Thomas Aquinas. His writings on philosophical subjects are numerous and valuable. The most remarkable are,—*Osservazioni intornò al Bosforo Tracio overo Canale di Constantinopoli*, Rome, 1681, in folio; *Dissertatio de Generatione Fungorum*, ibid. 1714, in folio, rare and curious; *Briève Ristretto del Saggio Fisico intorno alla Storia del Mare*, Venice, 1711, in folio, translated into French by Leclerc under the title of *Histoire Physique de la Mer*, Amsterdam, 1725, in folio; *Danubius Panonico-Mysicus Observationibus Geographicis, Astronomicis, Hydrographicis, Historicis, Physicis, perlustratus*, Hague, 1726, in 6 vols. large folio; *Etat Militaire de l'Empire Ottoman, de son Progrès, et de sa Décadence*, in French and Italian, Amsterdam and Hague, 1732, in folio, with 44 plates, and a map of the Ottoman Empire by Abubekir Effendi, with the names in the Turkish language. Marsigli died at Bologna on the 1st of November 1730.

MARSIVAN, or Marsovan, a village of Asiatic Turkey, pashalic of Sivas, situated on a wide plain, 24 miles W.N.W. of Amasia. It contains about 6000 houses, and has several mosques and fountains. Some manufactures of cotton fabrics are carried on here. Marsivan is believed to occupy the site of the ancient *Phagemon*.

MARSTON, John, a dramatist and satiric poet of the Elizabethan age, is supposed to have been born about 1575. The facts of his biography are very few and very uncertain. Anthony Wood supposes, but for no satisfactory reasons, that he was educated at Corpus Christi College, Oxford. As early as 1601 he was of sufficient importance as a writer to be satirized, under the name of Demetrius, in Ben Jonson's *Poetaster*. This enmity between the two authors seems to have afterwards subsided, for in 1605 Marston dedicated to Jonson, with expressions of affection and esteem, *The Malcontent*, a play which he had altered from Webster. In the same year also he was assisted by Jonson and Chapman in the composition of *Eastward Hoe*. For some reflections against the Scots in this comedy the authors were thrown into prison by the king, and were only released after they had lain for some time in the horrifying expectation of having their ears cut off and their noses slit. Shortly after this the intimacy between Marston and Jonson appears to have been once more interrupted. The former, in his preface to his *Sophonisba*, published in 1606, hints at the plagiarisms from Roman authors that are found in the *Catiline* and *Sejanus* of the latter; while Jonson, during his sojourn in 1619 with Drummond of Hawthornden, refers to an enmity between him and Marston that had subsisted for a considerable time. The life of Marston can be traced as far down as 1633. With little of the imitative and inventive genius of the dramatist, Marston had much of the spirited vigour and pungent wit of the satirist. In the *Scourge of Villainy*, the best of his satires, he is lofty and intrepid in his censure of vice, but is often carried by his vehement invective to the very verge of coarseness and indecency. In addition to those already mentioned, his other works are,—*The Metamorphosis of Pigmalion*, a satire, 16mo, London, 1598; *Antonio and Mellida*, a tragedy, 4to, 1602; *Antonio's Revenge*, a tragedy, 4to, 1602; *The Dutch Courtesan*, a comedy, 4to, 1605; *Parasitaster*, a comedy, 4to, 1606; *What You Will*, a comedy, 4to, 1607; *The Insatiate Countess*, a tragedy, 4to, 1613. Marston's miscellaneous poems were edited by Mr Bowle, 12mo, London, 1764.

MARTA, or Martha Santa, a town of New Granada, South America, capital of a province of the same name in the department of Magdalena. It stands on the Caribbean Sea, 105 miles N.E. of Cartagena, in Lat. 11. 15. N., Long. 74. 18. W. It was founded in 1525, and was constituted an episcopal city four years afterwards. It was repeatedly sacked by pirates during the sixteenth and seventeenth centuries; and in 1672 was completely pillaged by a French and an English vessel. Latterly, however, it rose into considerable importance as a commercial city, and enjoyed the almost exclusive privilege of importing goods for the capital of the country. It suffered much from the attacks of the Indians during the revolutionary war, and does not appear to have regained its former importance. The harbour is one of the best on this coast, having sufficient depth of water and good holding ground. It is defended by a castle on the summit of an isolated and almost perpendicular rock, and by several batteries. The cathedral is a very conspicuous object; but neither its architecture nor its internal decorations are worthy of notice. The climate is salubrious, although in summer the heat is very great; and the town is abundantly supplied with water. Pop. about 8000

MARTABAN. See Pegu.

MARTIALIS, M. Valerius, the famous Latin epigrammatist, was born on the 1st of March A.D. 43 at Bilbilis (*Bambola*) in Spain. He was educated at Calagurris (*Calahorra*), and repaired to Rome in 66. The fame of his epigrams soon spread through the city, and had even passed into Gaul, Germany, and the uncivilized countries of the north. Patronized successively by the Emperors Titus and Domitian, Martial was raised to the Equestrian Order and to the tribuneship, and received the honourable privilege called *jus trium liberoram*. He seems to have acquired a fair fortune, for he talks with the complacency of a proprietor about his mansion in the city and his country house at Nomentum. Disheartened probably by the small encouragement extended to literature under Trajan, Martial left Rome in 100, after a sojourn of 35 years. On his departure, his friend the younger Pliny, in return for a complimentary address. gave him a sum of money to defray his travelling expenses. This fact, by an inference not quite legitimate, has been made the ground of a common opinion that the epigrammatist at this time was in straitened circumstances. From Rome Martial immediately repaired to his birthplace, and there he seems to have married Claudia Marcella, a lady whose graces and accomplishments he celebrated with affectionate pride. He passed his latter years on the property of his wife, near the banks of his native Salo (*Xalon*). The time of his death is unknown, but it was probably after A.D. 104.

The pieces of Martial generally known as his *Epigrams* amount to 1500, divided into fourteen books. Of these books the two last, called respectively *Xenia* and *Apophoreta*, consist entirely of distichs descriptive of the small articles of luxury and ornament which the Romans usually presented to their friends on festal seasons. In addition to these epigrams, Martial wrote what is commonly known as

Liber de Spectaculis, a work of thirty-three pieces on the shows exhibited by Titus and Domitian. It is doubtful whether all the poems of Martial are extant, and whether all those now ascribed to him are genuine. The best editions of Martial are those of Scriverius, Leyden, 12mo, 1619; Amsterdam, 12mo, 1621, and 16mo, 1629; Lemaire, 3 vols. 8vo, Paris, 1825; and Sschneidewinn, 2 vols. 8vo, Grem. 1842. Martial was translated into French verse by Marolles, 4to, Paris, 1675. His select pieces have been translated into English metre, and published in London, by May, 1629; Fletcher, 1656; Hughes, 1737; Hay, 1754; Wright, 1763; Rogers, 1782; and Elphinstone, 1783,—the dullest of them all. There is an old MS. of Martial in the Advocates' Library, Edinburgh.

In the hands of Martial the epigram first became a short poem abounding with ingenious and pointed thoughts, and compressing in its conclusion all the pith of its preceding parts. To him, therefore, this species of poetry owes its present form. Amid much of the forced ingenuity and over-laboured expression that always attend epigrammatic composition, Martial displays a refined felicity of diction, a fertile fancy, and a wit equally delicate and pungent. He also shows at times a love and talent for the description of rural scenes. More interesting, however, to the modern student is the full and minute delineation which he gives of the public and private customs of his age. Yet all these estimable qualities are neutralized to a considerable extent by the shameless obscenity that abounds in his writings, and the mean-spirited adulation which he lavishes upon Domitian. These open offences against morality and self-respect, after every possible palliation has been pleaded for them, must always affect the character of Martial both as a man and as an author.

MARTIGUES, a town of France, department of Bouches-du-Rhone, and arrondissement of Aix, is situated on the channel between the lagoon of Berre and the Mediterranean, 15 miles N.W. of Marseille. It consists of three distinct parts,—the town proper, called the Isle, on an island in the channel, and the suburbs of Jonquières and Ferrières, the former on the south and the latter on the north bank. Its situation has acquired it the designation of the Venice of Provence. The town is generally well and regularly built, and has several handsome buildings. It carries on an active coasting trade. Pop. 8000, most of whom are engaged in fishing.

MARTIN, Louis-Aimé, a distinguished French writer of the present century, was born at Lyons in 1779. After having received an excellent education in his native city, he set out for Paris at the age of twenty, and became connected with the *Journal des Débats*, for which he contributed articles on scientific subjects. By his *Lettres à Sophie sur la Physique, la Chimie, et l'Histoire Naturelle,* published in 1810, he gained for himself an honourable position among the rising literary men of his time, and which was more than confirmed a short time afterwards by his lectures at the *Athénée* on the literary history of France. He was appointed to a secretaryship under the Chamber of Deputies; and delivered a course of lectures during the same year to the École Polytechnique on the History of France, which he followed up in 1830 by a course on the History of Germany. Martin became early imbued with the somewhat extravagant ideas of progress then current in France, and devoted himself with praiseworthy energy to the realization of his cherished schemes for the regeneration of human society. He advanced new systems of instruction, projected communal libraries, and took a principal share in founding the Panthéon Littéraire, a collection of the *chefs-d'œuvre* of all nations, which, by popularizing instruction, were designed to improve the character, and increase the happiness of men. He published his views on this subject in his *Plan d'Une Bibliothèque Universelle; Etudes des Livres qui peuvent servir à l'Histoire Philosophique de Genre Humain*, Paris, 1837. But Martin soon became alive to the fact, that his plans for securing the welfare of humanity were not quite so enlightened or profound as he had been led to believe, and that the perfecting of mechanical contrivances, and the construction of railways, while ministering to the material comforts of a people, tend, besides, to augment their wants, and increase their desire for gratifying them. Accordingly, in his work *De l'Education des Mères de Famille*, dedicated to M. Lamartine, which received the prize from the French Academy in 1835, he endeavoured to conduct men to a higher order of truths, and pointed them to religion as the true source of earthly happiness. His ideas on religion, however, did not meet with the approval of the Roman Catholic church, and his book for the edification of the mothers of France was placed on the *Index.* A warm admirer of Bernardin de Saint Pierre, Aimé Martin married the widow of that eminent writer, collected his writings, and vindicated his memory from the unjust attacks to which it had been exposed. He died at Saint Germain-en-Laye on the 18th November 1847, aged sixty-two; and his friend M. de Lamartine pronounced an eloquent funeral oration over his tomb.

In addition to his other works, Aimé Martin published excellent editions of the works of Molière and of Racine, with notes; of the *Maximes* of La Rochefoucauld, with a critique; of the *Œuvres Philosophiques* of Descartes; and of Fénélon's *Traité de l'Existence de Dieu,* with additions.

MARTIN, *Benjamin*, an eminent artist and mathematician, was born in 1704. After publishing a variety of ingenious treatises, and particularly a scientific magazine under his own name, and carrying on for many years an extensive trade as an optician and globe-maker in Fleet Street, the growing infirmities of age compelled him to withdraw from the active duties of business. Trusting too fatally to what he thought the integrity of others, he unfortunately (though with a capital more than sufficient to pay all his debts) became bankrupt. The unhappy old man, overpowered by this unexpected blow, attempted in a moment of desperation to destroy himself; and the wound he gave himself, though not immediately mortal, hastened his death, which happened on the 9th February 1782, in his seventy-eighth year. He had a valuable collection of fossils and curiosities of almost every kind, which, after his death, were disposed of by auction. His principal publications are,—

The Philosophic Grammar, being a View of the Present State of Experimental Physiology, or Natural Philosophy, 1735, 8vo; *A New, Complete, and Universal System or Body of Decimal Arithmetic,* 1735, 8vo; *The Young Student's Memorial Book, or Patent Library,* 1735, 8vo; *Description and Use of both the Globes, the Armillary Sphere, and Orrery,* 1736, in 2 vols. 8vo; *Memoirs of the Academy of Paris,* 1740, in 5 vols.; *System of the Newtonian Philosophy,* 1759, in 3 vols.; *New Elements of Optics,* 1759; *Mathematical Institutions, viz., Arithmetic, Algebra, Geometry, Trigonometry, and Fluxions,* 1759; *Natural History of England, with a Map of each County,* 1759, in 2 vols.; *Philology and Philosophical Geography,* 1759; *Mathematical Institutions,* 1764, in 2 vols.; *Lives of Philosophers, their Inventions, &c.,* 1764; *Introduction to the Newtonian Philosophy,* 1765; *Institutions of Astronomical Calculations,* in 2 parts, 1765; *Description and Use of the Air-Pump,* 1766; *Description of the Torricellian Barometer,* 1766; *Appendix to the Description and Use of the Globes,* 1766; *Philosophia Britannica,* 1778, in 3 vols.; *Gentleman and Lady's Philosophy,* in 3 vols.; *Miscellaneous Correspondence,* in 4 vols.; *System of Philology; Philosophical Geography; Magazine,* complete in 14 vols.; *Principles of Pump-work; Theory of the Hydrometer;* and *Doctrine of Logarithms.*

MARTIN, *David*, an eminent Protestant divine, born at Revel in 1639. After the revocation of the Edict of Nantes he went to Holland, and became pastor and professor of theology and philosophy, where he remained till his death in 1721. He is best known by his editions of the Scriptures. The most popular of his biblical works is his *History of the Old and New Testament*, 2 vols. folio, Amst. 1700, known as "Mortier's Bible."

Martin, *John*, one of the most celebrated painters of the present century, was born at Haydon Bridge, near Hexham, Northumberland, on the 19th of July 1789. Having early expressed a desire to become a painter, his father decided upon apprenticing him to a coach-builder in Newcastle, to learn herald-painting, whither his family had removed. In consequence of a quarrel with his master, who does not seem to have treated young Martin very handsomely, the aspiring artist, eager "to practise," as he says himself, "the higher mysteries of the art," after having his original indentures cancelled, was placed under Bonifacio Musso, an Italian painter of considerable merit, and father of the eminent enamel-painter Charles Musso or Muss. Martin removed to London with his Italian master in September 1806, where he was engaged in painting on china and glass, "by which," he says, "and making water-colour drawings, and teaching, I supported myself; in fact, mine was a struggling artist's life when I married, which I did at nineteen." During his two years' residence in London, Martin applied himself with indefatigable industry during his leisure hours to the study of perspective and architecture, labouring till two or three o'clock in the morning in the depth of winter;" and stimulated now by new responsibilities, he resolved to put forth a bold effort, and paint a large picture. This resolution he carried into effect; and after a month's application, he gave to the world in 1812 his first work, "Sadok in search of the Waters of Oblivion," which was admitted into the exhibition of the Royal Academy, and subsequently purchased for fifty guineas. His next works were the "Paradise," which obtained a place in the great room of the Academy, and the "Expulsion," which was sent to the British Institution. His next paintings, "Clytiæ" and "Joshua," were placed by the Academy in an ante-room, a circumstance which so offended Martin, that he removed his name from their list of candidates for membership, and by the laws of the academicians was thus rendered incapable of afterwards receiving any distinction at their hands. But the ultimate success of his "Joshua" amply compensated for the neglect shown to it by the Academy. This striking production was afterwards exhibited at the British Institution, and carried off the prize of the year. "The success of my 'Joshua,'" says Martin, "opened a new era to me." The attention excited by his next picture, the "Fall of Babylon," which appeared in 1819, was second only to that of the "Belshazzar." "Macbeth," one of his most successful landscapes, appeared the following year; and in 1821 he completed his elaborate picture of "Belshazzar's Feast," on which he had wrought an entire year, and which was awarded the premium of L.200 by the British Institution. Martin had now attained a wide celebrity, and thus his most famous painting met at once with vehement opposition and unhesitating praise. His paintings were engraved, and found an extensive sale all over the kingdom. During all this storm of excitement this adventurous artist held on his way, and produced his "Destruction of Herculaneum" in 1822; the "Seventh Plague" and "Paphian Bower" in 1823; the "Creation" in 1824; the "Deluge" in 1826; and the "Fall of Nineveh" in 1828—one of the most popular of all Martin's works. The cycle of his great works was now completed, and while his later pictures met with admirers, the enthusiasm awakened by his earlier efforts did not reappear. His hands were now full with the illustrations of Milton, which he drew on plates, and for which he received 2000 guineas. Martin was now much before the public in connection with various plans for improving the city of London, an object which he had deeply at heart, and for which he laboured with much energy during the last twenty years of his life. Occupied with these projects, Martin laid aside his pencil for some time, and on resuming it, found that his power had greatly left him. Yet his "sublime style" was continued during the rest of his life. He produced "The Death of Moses" and "The Death of Jacob" in 1838; "The Eve of the Deluge" and "The Assuaging of the Waters" in 1840; "The Celestial City and River of Bliss" and "Pandemonium" in 1841; "The Flight into Egypt" in 1842; "Christ Stilling the Tempest" and "Canute the Great rebuking his Courtiers" in 1843; "Morning and Evening" in 1844; "The Judgment of Adam and Eve" and "The Fall of Adam" in 1845; "Evening—Coming Storm" in 1846; "Arthur and Ægle in the Happy Valley" in 1849; "The Last Man" in 1850; "Valley of the Thames, viewed from Richmond Hill," in 1851; "Scene in a Forest—Twilight," 1852. Martin had been employed for the last four years on three great pictures illustrative of the last judgment, entitled "The Judgment," "The Day of Wrath," and "The Plains of Heaven," at which he laboured until within a few weeks of his death, and which he left unfinished. Having been attacked with a stroke of paralysis, he repaired to Douglas, Isle of Man, in quest of health, where he died on the 9th of February 1854. (See Martin's Autobiographic Notes in the *Athenæum* of February 25, 1854.)

Martin during his day had no rival in point of popularity, except Turner the great master of landscape. Martin's brother artists not unfrequently found much in his style to censure. Leslie, who was one of his warmest friends, while admiring the original power of Martin, found frequent occasion to dissent emphatically from his mode of treatment. His merits and defects were alike unquestionable; and it was the bold originality of the man that provoked so much criticism. In his expression of material grandeur he addressed the eye rather than the mind; in his delineations of the awful and the terrible in nature his imagination outran his judgment. Yet he triumphantly succeeded in ravishing the senses of the multitude, and in dazzling the eyes even of sagacious men. Whether it was by an illusory trick rather than by a stroke of genius, by bold theatrical display rather than by the chastened power of an exalted imagination, that Martin captivated the eyes of his admirers, he at all events acquired a very great popularity, and so long as his manner was new, he was enthusiastically applauded as a man of pre-eminent genius. He was certainly gifted with a power to fascinate, but familiarity was calculated to break the spell.

Martin, *Louis-Claude de Saint*, called the "Unknown Philosopher," was born at Amboise, of a noble family, on the 18th of January 1743. Originally designed for the magistracy, he preferred the profession of arms; and at the age of twenty-two became an officer in the regiment of Foix, and was made a chevalier of St Louis in 1789. His taste for spiritualism induced him to enter the secret school of Martinez Pasqualis, where he had an opportunity of becoming acquainted with the theurgical operations practised at that institution. Though originally disposed to believe in that system, he nevertheless ultimately abandoned its mystical labyrinths for the pursuit of a purer spiritualism. While not embracing all the ideas of J. J. Rousseau, he yet displayed a profound sympathy for that philosopher. But his unhesitating admiration was reserved for the Teutonic philosopher Jacob Boehm, whose singular writings—many of which Saint Martin translated—stamp with a character of originality the illuminism of the early part of the seventeenth century. The Revolution, in its various phases, found Saint Martin always the same. He saw in it the designs of Providence, and recognised equally a predestined instrument in the remarkable man who ultimately put an end to its excesses. Appointed in 1794 to give lectures at the normal schools, Saint Martin publicly refuted with great success the materialism of Garat, professor of mental philosophy at that institution. His life, nevertheless, remained obscure, being known only to a narrow circle of distinguished friends, who knew how to appreciate him. It was with one of those, Count Lenoir Laroche, at Aunay, that he died of an attack of apoplexy on the 13th of October 1803.

A Life of the "Unknown Philosopher" was written by M. Gence in 1824. The sect called "Martinists" at the epoch of the Revolution did not receive their name from Saint Martin, as many have supposed, but from his master, Martinez Pasqualis. (*Dictionnaire des Sciences Philosophiques.*)

The principal works of this eminent mystic are,—*Des Erreurs et de la Verité*, 1775; *Tableau Naturel des Rapports qui Existent entre Dieu, l'Homme, et l'Univers*, 1782; *Lettre à un Ami sur la Revolution Française*, 1795; *Eclair sur l'Association Humaine*, 1797; *Quelles sont les Institutions les plus propres à Fonder la Morale d'un Peuple*, 1798; *L'Homme de Desir*, 1790; *Ecce Homo*, 1792; *Le Nouvel Homme*, 1792; *De l'Esprit des Choses*, 1800; *Discours en Reponse au Citoyen Garat*, 1802; *Le Ministre de l'Homme Esprit*, 1802. Also, two volumes of posthumous works, entitled *Quelle est la Manière de Rappeler à la Raison les Nations, tant Sauvages que Policées, qui sont Livrées à l'Erreur ou aux Superstitions de tout Genre?* 1807.

MARTIN, ST, one of the West India Islands, belonging partly to France and partly to Spain. (See GUADALOUPE.)

MARTINI, GIOVANNI BATTISTA, the most learned musician of the eighteenth century, was born at Bologna on the 25th of April 1706. His father, Antonio Maria Martini, a violinist, taught him very early the elements of music, and to play on the violin. He was then instructed in singing and harpischord-playing by Padre Predieri, and afterwards in counterpoint by Antonio Riccieri. After the requisite religious studies and training, he took holy orders as a Franciscan on the 11th September 1722. He cultivated the theory and practice of music so successfully, that although only nineteen years old, he was appointed in 1725 chapel-master of the church of St Francis at Bologna. In the composition of religious music he received instructions from Jacopo Perti. He studied mathematics under Zanotti, and devoted much of his time to the reading of ancient and modern works on music. He was constantly collecting such works, and at last was in possession of the most extensive musical library that had ever been formed.[1] The books and MSS. of the Cavaliere Ercole Bottrigari, a distinguished amateur, formed a part of Padre Martini's library; and it has been stated repeatedly that they were left to him as a legacy by Bottrigari,—a statement utterly disproved by dates, for Bottrigari died in 1612, and Martini was born in 1706. At Bologna Padre Martini opened a school of musical composition, in which several celebrated musicians were trained. Among his best pupils were Padre Paolucci, Padre Sabbatini, Rutini, Zanotti, Sarti, the Abate Ottani, and the Abate Stanislao Mattei. Padre Martini always declared his preference for the ancient Roman school of musical composition. His school became so celebrated throughout Europe, that the best musicians consulted him on doubtful points. Burney, in his musical tour through France and Italy in 1770, gives a most pleasing account of the amiable manners and character of Padre Martini. After long and patient suffering under a complication of diseases, Martini expired at Bologna on the 4th of August 1784. The greater part of his compositions for the church are unpublished. In 1734 he published some church music for four voices, and in 1736 sonatas for organ and harpsichord. Of his sonatas for organ and harpsichord, published in 1747, Clementi has given several in the second volume of his *Practical Harmony*. In 1763 Martini published chamber duetts for different voices. His most important works are his *Storia della Musica*, of which three volumes only appeared, and his *Saggio di Contrappunto*. The former exhibits prodigious reading and industry, but is written in a dry style, and is overloaded with matter belonging to the regions of conjecture. The fourth volume, which he left incomplete, and which has not been published, was to contain inquiries regarding the music of the middle ages, down to the eleventh century. At the beginning and end of each chapter of his musical history Martini gives enigmatical canons, some of which are exceedingly puzzling. Cherubini resolved the whole of them. His *Saggio di Contrappunto* is a very learned and valuable work, in two volumes 4to, and contains numerous examples by the best masters, with excellent explanatory notes. It treats chiefly of the tonalities of the plain-chant, and of counterpoints constructed upon them. Besides several controversial works published by Martini, he drew up a *Dictionary of Ancient Musical Terms*, which was published in the second volume of the collection of G. B. Doni's works, in three volumes folio. He published also a work on *The Theory of Numbers as applied to Music*; and a paper on the "Use of Geometrical Progression in Music." (G. F. G.)

MARTINIQUE, one of the French West India Islands, the most northern of the Windward group, lies between Lat. 14. 24. and 14. 53. N., and Long. 60. 50. and 61. 18. W., about 20 miles N. of St Lucia. It is very irregular in form, and is about 50 miles in length from N.W. to S.E., by about 15 in mean breadth. Area 382 square miles. The surface is uneven and mountainous, and has several extinct volcanoes. The highest point in the island, Mont Pelee, rises to the height of 4450 feet. Extensive masses of volcanic rocks cover the interior, and extend from the mountains to the shore, where they form lofty cliffs. Between the volcanic rocks broad irregular valleys of great fertility occur. Those on the W. side, called *Basse-Terre*, are more extensive and fertile than those on the E. side, called *Cabes-Terre*. The valleys are watered by a great number of small streams. About two-fifths of the surface are under cultivation, the remainder being covered with trees, or occupied by naked rocks. The principal productions are sugar, coffee, cocoa, &c. The exports for the year ending 31st December 1851 were,—sugar, 51,610,160 lb.; coffee, 224,590 lb.; cocoa, 318,595 lb.; cassia, 360,669 lb.; logwood, 110,682 lb.; molasses, 7427 gallons; rum, 234,297 gallons. In 1854 the total value of exports from this island to France was L.552,000; of imports from France L.816,000. The coast being indented by numerous bays and inlets, affords many good harbours. There are two towns on the island, Port Royal and St Pierre; the former the capital, but the latter the more populous, and the centre of commerce. For administrative purposes it is divided into two arrondissements, fourteen cantons, and twenty-six communes; and is under a governor, with a privy council of seven members, and a colonial council of thirty members. Martinique, the native name of which is *Madiana*, was discovered by the Spaniards in 1493, and colonized by the French in 1635. It was taken by the English in 1762, and again in 1794 and 1809; and was finally given up to France in 1814. Pop. (1854) 123,701.

MARTINUS, Bishop of Tours, a celebrated ecclesiastic, was born of heathen parents at Sabaria (*Steinam-Anger*) in Pannonia about 316. After receiving his education at Pavia, he entered the army at the age of sixteen, and served successively under Constantius and Julian. While stationed in Gaul he was admitted into the Christian church by baptism, and abandoning soon afterwards the profession of arms, he was consecrated to the priesthood by Hilarius of Poitiers. Having returned to Pannonia, he converted his mother, and became noted for his fearless opposition to the Arians, who were then on the ascendant. Directing his steps once more towards Gaul, he founded on his way a monastery at Milan, and sojourned in its retirement for some time. On his arrival at Poitiers about 360, he built another monastery on a piece of ground which had been presented to him by Hilarius. In 371, so high had his alleged miraculous power, his fanatical piety, and his sordid austerities raised him in the estimation of the populace, that the inhabitants of Tours forced him to become their bishop. Finding, however, that the miserable cell in which he had taken up his abode was not a sufficient protection against the flocks of his admiring visitors, he built the monastery of Marmontier, on the banks of the Loire, and there he secluded himself for the rest of his life. Martinus died in his eightieth year, near the close of the fourth century. For many years afterwards his memory was held in the greatest veneration, not only in France, but in other countries of Europe. An invocation of St Martin was universally regarded a sovereign remedy for all diseases, whether bodily, mental, or moral. His Life by Sulpicius Severus, one of his disciples, is still extant. The *Confessio Fidei de Trinitate*, usually attributed to Martinus, is of doubtful authenticity.

---

[1] See the article BURNEY, in which Martini's books and MSS. are noticed as they remained in 1819.

MARTOS, a town of Spain, province of Jaen, stands on the slope of a steep hill, which is surmounted by a ruined castle, 16 miles W.S.W. of Jaen. The streets are steep, narrow, crooked, and unpaved; but there are some handsome public buildings, including several churches, chapels, and convents, town-house, prison, hospital, theatre, and orphan asylum. It is a place of resort on account of its mineral waters; and it has two bathing establishments. Pop. about 10,000.

MARTOS, IVAN PETROVICH, an eminent sculptor, sometimes called "The Canova of Russia," was born about 1755 at Itchnia in Little Russia. He removed at an early age to St Petersburg; and in course of time his works had attained so high a position that he was sent as a pensioner to Rome, where he sojourned for three years, zealously studying his art, and cultivating an intimacy with the famous painters Raphael Mengs and Pompeo Batoni. On his return to his native country, he was employed by government in adorning the principal cities of Russia with monuments of eminent men. Accordingly, he executed a colossal group in bronze of Minin and Pozkarski at Moscow, and erected a monument to the Emperor Alexander at Taganrog, to the Duke of Richelieu at Odessa, to Lomonozov at Archangel, and to Potemkin at Kherson. Martos was for many years director of the Academy of Fine Arts in St Petersburg. He died in that city in April 1835. The chief excellence in the works of Martos is the simple and natural drapery of his figures. He also surpassed his contemporaries in subjects of bas-relief.

MARTYN, HENRY, a celebrated missionary, was born in 1781 at Truro in Cornwall, where his father, a man of singular piety and intelligence, was a labourer in the mines of Gwennap, and subsequently a merchant's clerk in Truro. He received his education at the grammar school of his native town, and at St John's College, Cambridge, which he entered in 1797, and pursued his studies so successfully, that in January 1801 he obtained the highest academical honour of senior wrangler, and in 1802 was chosen a fellow of his college, besides gaining the highest prize of the university for Latin prose composition. During this brilliant career the mind of Martyn became seriously occupied with the truths of religion, induced to some extent, it is believed, by the death of his father, which produced a very serious impression on the ardent and thoughtful student. These impressions were fostered by the intimacy which Martyn had formed with the celebrated university preacher, the Rev. Charles Simeon. Notwithstanding the bright prospects of advancement which his talents opened up to him, he resolved to devote the energies of his life to the work of a Christian missionary; and accordingly, after some preliminary preparation, he in 1805 left the banks of the Cam for the shores of India as a chaplain in the East India Company's service. He commenced his labours among the Europeans at Dinapore, and soon found himself capable of extending his labours, by conducting divine worship among the natives in their own vernacular language, and by establishing schools for their instruction. It was not till 1809, however, that his regular public ministrations among the heathen commenced. In the spring of that year he was removed to Cawnpore, where he was exposed to great privation, having to preach in the open air, under a burning Indian sun. Martyn, nevertheless, zealously pursued his noble work among the hundreds of heathen mendicants who crowded around him. During his residence at Dinapore he had been engaged in revising the sheets of his Hindustanee version of the New Testament, and in superintending the Persian translation executed by Sabat; and having now perfected himself in the latter language, he resolved to extend his missionary labours to Persia. He accordingly took up his residence at Shirauz, where he occupied himself in revising, with the aid of the learned natives, his Persian and Arabic translations of the New Testament, and in conducting religious conversations and discussions among the moollahs and soofis, many of whom were greatly impressed by him. "Henry Martyn," said a Persian moollah, "was never beat in an argument. He was a good man; a man of God." Here, in addition to his New Testament, he executed a Persian translation of the Psalms,—"a sweet employment," as he says in a letter, "which caused six weary moons that waxed and waned since its commencement to pass unnoticed." Having made an unsuccessful journey to Tabriz to present the shah with his translation of the New Testament, he was seized with fever, which so thoroughly prostrated his energies, that after a temporary recovery, he found it necessary to seek a change of climate. He set out for Constantinople, and after a hurried march of great suffering he got as far as Tokat in Asia Minor, where he was compelled to stop from utter prostration, and falling either a sacrifice to the plague which then raged there, or sinking under his previous disorder, he died on the 16th October 1812, in his thirty-second year. The news of his death was received in England with deep regret. In addition to his valuable labours as a translator, by which he placed portions of the Scriptures within the reach of all who could read over one-fourth of the habitable globe, he was instrumental in leading a considerable number of Hindus and Mohammedans to profess their adherence to the Christian faith. From one who had accomplished so much in a great cause in the very dawn of his career, it was not singular that much should have been expected from him ere he was called upon to retire from the field. Yet during his brief career he earned for himself a foremost place among modern missionaries; and the name of Henry Martyn will be held in honour as long as noble Christian heroism is admired among men. (See *Memoir of the Rev. Henry Martyn*, by the Rev. John Sargent, London, 1819.)

MARTYR (μάρτυρ) signifies properly *a witness*, and is applied in the New Testament—1. To judicial witnesses (Matt. xviii. 16; xxvi. 65, &c.). 2. To one who has testified, or can testify, to the truth of what he has seen, heard, or known. This is a frequent sense in the New Testament, as in Luke xxiv. 48; Acts i. 8, 22, &c. 3. The meaning of the word which has now become the most usual is that in which it occurs most rarely in the Scripture, *i.e.*, one who by his death bears witness to the truth. In this sense we only find it in Acts xxii. 20; Rev. ii. 13; xvii. 6. This now exclusive sense of the word was brought into general use by the early ecclesiastical writers, who applied it to every one who suffered in the Christian cause. (See Suicer, *Thesaurus Eccles.* sub voc.) Stephen was in this sense the first martyr; and the spiritual honours of his death tended in no small degree to raise to the most extravagant estimation, in the early church, the value of the testimony of blood. Eventually a martyr's death was supposed, on the alleged authority of the under-named texts, to cancel all the sins of the past life (Luke xii. 50; Mark x. 39); to supply the place of baptism (Matt. x. 39); and at once to secure admittance to the presence of the Lord in Paradise (Matt. v. 10–12). In imitation of the family custom of annually commemorating at the grave the death of deceased members, the churches celebrated the deaths of their martyrs by prayer at their graves, and by love-feasts. From this high estimation of the martyrs, Christians were sometimes led to deliver themselves up voluntarily to the public authorities—thus justifying the charge of fanaticism brought against them by the heathen. For the most part, however, this practice was discountenanced, the words of Christ himself being brought against it; Matt. x. 23. (See Gieseler, *Eccles. Hist.* i., 109, 110; Neander's *Church Hist.* i., p. 463.)

MARTYR, PETER, a famous reformer, whose family name was Vermigli, was born at Florence in 1500. At the age of sixteen he became an Augustine monk of the monastery of Fiesole, and was afterwards employed in teaching philosophy, theology, and Greek at Padua, and in preaching in the principal cities of Italy. He was led to renounce the Romish creed through a perusal of the writings of Luther and Zwingle, and was accordingly, in 1542, forced to flee before the persecuting zeal of his brother-priests. After sojourning successively at Zurich and Basle he became professor of divinity at Strasburg. Invited to England in 1549 by Archbishop Cranmer, he was appointed in the same year to a theological chair at Oxford. The accession of Mary, however, in 1553, obliged him to resign his appointment, and to return to his former chair at Strasburg. Soon after his departure from England, the remains of his deceased wife were disinterred at Oxford, and buried under a dunghill. In 1556 Martyr was translated from Strasburg to a theological professorship at Zurich. He died there in 1562. Of Peter Martyr's numerous theological treatises, his *Loci Communes*, published at Geneva in 1624, is best known.

MARTYROLOGY, a catalogue or list of martyrs, including the history of their lives and sufferings for the sake of religion. The Martyrology of Eusebius of Cæsarea was the most celebrated in the ancient church. It was translated into Latin by St Jerome, but it is not now extant. That attributed to the venerable Bede, in the eighth century, is of very doubtful authority, there being found in it the names of several saints who did not live till after his time. The ninth century was very fertile in martyrologies; for then appeared that of Florus, subdeacon of the church at Lyons, who, however, only filled up the chasms in Bede. This was published about the year 830, and was followed by that of Waldenburtus, monk of the diocese of Trèves, written in verse about the year 844; and this again by that of Usuard, a French monk, which was written by the command of Charles the Bald in 875, and is the martyrology now ordinarily used in the Roman Catholic church. That of Rabanus Maurus, written about the year 845, is an improvement on Bede and Florus; that of Notker, monk of St Gall, was written about the year 894. The martyrology of Addo, monk of Ferrières, in the diocese of Trèves, afterwards archbishop of Vienne, was compiled from the Roman in 858. According to Du Sollier, the martyrology of St Jerome is the great Roman martyrology; from this was made the little Roman one printed by Rosweyd; and of this little Roman martyrology was formed that of Bede, afterwards augmented by Florus. The martyrology of Nevelon, monk of Corbie, written about the year 1089, is little more than an abridgement of that of Addo. Father Kircher also makes mention of a Coptic martyrology preserved by the Maronites at Rome. Middleton, in his *Letter from Rome*, has satisfactorily shown that many of the accounts in the martyrologies are pure fabrications; and that persons who never existed, inanimate objects, and heathen deities, have been canonized as martyrs and saints. We have likewise Fox's *Book of Martyrs*, containing valuable accounts of the sufferings of the Reformers. (For further information on this subject consult Ruinart's *Acta Martyrum;* Dodwell's *Dissertationes Cyprianicæ;* Dr Middleton's *Free Inquiry, &c.*, and Maitland's *Church in the Catacombs.*)

MARVELL, ANDREW, an English patriot of the seventeenth century, enjoys the distinction of having been the friend of Milton, the last member of Parliament who received wages from his constituents, and one of the most acute, learned, and witty controversialists and satirists of his age. He was born at Winestead in Holderness, county of York, on the 2d of March 1621. His father, a clergyman, afterwards removed to Hull, as lecturer in Trinity church, and master of the grammar school of that town. The death of the elder Marvell took place in 1640, under circumstances too remarkable to be ever forgotten in the Yorkshire calendar. He had agreed to cross the Humber with a young couple whom he was to marry at Barrow in Lincolnshire. The day was stormy, and the minister, though persuaded to share the danger of the passage, was so strongly impressed with a presentiment it would prove fatal, that, on entering the boat, he threw his cane ashore, exclaiming, "Ho, for heaven!" His fears were realized—the boat went down, and all on board perished. The parents of the affianced lady, it is said, adopted young Marvell as their son, and enabled him to travel abroad. He had when very young been entered of Trinity College, Cambridge, but was seduced away from the university by some Jesuit emissaries. His father found him in London and took him back to college, and Marvell ever afterwards was a firm friend of Protestant freedom and enlightened toleration. From a letter of Milton's to Secretary Bradshaw (discovered so late as 1826 in the State Paper Office), it appears that Marvell spent four years abroad in Holland, France, Italy, and Spain, and on his return was engaged in giving instruction in the languages to a daughter of Lord Fairfax. He had also been engaged by Cromwell to superintend the education of a Mr Dutton in Eton. In 1654 Marvell writes to Milton from Eton, describing his presentation of a copy of the *Defensio Secunda*, sent by Milton to Bradshaw (not to Cromwell, as Birch and Dr Symmons suppose). In 1657 Marvell was associated with Milton in the Latin secretaryship, the salary of each being the same, namely, L.200 per annum. In 1660 the citizens of Hull elected Marvell their representative in Parliament, and in December of that year we find him generously interposing in behalf of his illustrious friend the poet. Milton had been in the custody of the sergeant-at-arms, and Marvell complained that excessive fees, amounting to no less than L.150, had been extorted from him. The only answer which appears in the parliamentary history, is a remark by Finch, that Milton had been Cromwell's secretary, and deserved hanging! When the poet was afterwards attacked by an anonymous assailant (whom Marvell believed, but erroneously, to be the renegade Dr Samuel Parker), the member for Hull vindicated the character of his friend; and when *Paradise Lost* appeared, he was ready to greet the immortal epic and its author, "blind yet bold," with a copy of encomiastic verses. In his capacity of legislator Marvell was diligent and independent. He wrote daily to his constituents during the sitting of Parliament, and was the friend and counsellor of the small band of senators who firmly but cautiously resisted the arbitrary spirit of the court. When Parker inculcated the slavish doctrine of divine right and passive obedience, Marvell answered him in a vein of sarcastic raillery as well as sound argument, which Swift said he read with pleasure though Parker's work had long been sunk. Another treatise by Marvell, *An Account of the Growth of*

Popery and Arbitrary Power in England, was deemed so formidable, that a reward was offered for the discovery of the printer. His poetical satires are much inferior to those in prose—grosser, and deficient in lively illustration. They were, however, greatly admired in his own day; and there is a story that Charles II. having met Marvell at a private house, was so pleased with the conversation of the wit, whose works he had read, that he attempted to win him over to the court. With this view he despatched Danby, the lord treasurer, to Marvell's lodgings, "in one of the small courts of the Strand, up two pair of stairs;" and the treasurer offered a sum of L.1000, with a promise of future favours,—all which, it is said, Marvell steadily refused, though he was obliged, on the departure of the courtier, to send to a friend for the loan of a guinea. We have no faith in this traditionary anecdote, either as respects the king's liberality or Marvell's poverty, but it illustrates the popular opinion as to Marvell's simplicity and integrity of character. He died on the 20th of August 1678. His death was so sudden as to give rise to a suspicion of his having been poisoned, for which, however, there is not the slightest evidence or authority. His remains were interred in the church of St Giles-in-the-Fields, at the expense of his constituents, who also voted a sum for a monument; but the servility or resentment of the rector prevented the ashes of the patriot and friend of Milton from receiving this distinction. His memory was long cherished by the adherents of the "good old cause;" and besides his controversial and political services, Marvell had written some minor poems of great tenderness, fancy, and beauty, which were deservedly popular. His lyrical stanzas on the sailing of the emigrants for Bermudas, *Safe from the Storms and Prelates' rage*, form one of the finest strains of the Puritan muse. A complete collection of Marvell's works was published in 1777 in three vols. 4to, by a native of Hull, Captain Thompson, who had inherited the enthusiasm of a former generation for Marvell, but appears to have been lamentably deficient in editorial diligence and literary information. (R. C—S.)

MARWAR. See JOUDPORE.

MARY (Heb. מרים, Gr. *Μαριαμ* or *Μαρια*). Of persons bearing this name, no less than seven, if not eight, are mentioned in different parts of the sacred volume. They are the following:—

MARY or MIRIAM, *the sister of Aaron and Moses*. She was the daughter of Amram and Jochebed, who were both of the tribe of Levi (Exod. ii. 1), and were related to each other before marriage as aunt and nephew (Exod. vi. 20), and seems to have been their eldest child (Numb. xxvi. 59). When the infant Moses was exposed by his mother in the ark upon the Nile, Miriam, then probably about eight years of age, was sent to observe the fate of her brother; and when she beheld him picked up by the attendants of the daughter of Pharaoh, and saw the interest taken in him by that princess, she availed herself of the opportunity to have him again restored to his mother, by offering to procure for him a Hebrew nurse, and, when that offer was accepted, bringing his mother as the person she had selected (Exod. ii. 4–10). On the occasion of the destruction of the Egyptians in the Red Sea after the Israelites had passed safely over, Miriam, who, in the passage giving an account of the circumstance (Exod. xv. 20), is styled "the prophetess," either on account of her skill in extempore poetry and music,[1] or because she really enjoyed divine revelations,[2] led forth a chorus of women, and guided them in celebrating with music and dancing the triumphant deliverance which their nation had obtained. Shortly after this an event occurred which presents the character of Miriam in a less favourable light. Her brother Moses had been rejoined by his wife Zipporah, who had for a considerable time before been resident with her father Jethro (Exod. xviii. 1–3); and as she was not of Israelitish but of Cushite extraction, Miriam and her brother Aaron took occasion from this to indulge what seems to have been a long cherished feeling of jealousy and envy towards Moses, by exciting a prejudice against him in the minds of the people. For this she was punished by God, by being, in the sight of all the people, afflicted with leprosy, so that "she became white as snow." On the intercession, however, of Aaron with Moses, and of Moses with God, this terrible infliction was removed; but not until she had been "shut out from the camp seven days," during which time the people of Israel suspended their journey (Numb. xii.). From this a period of nearly forty years elapses during which no mention is made of Miriam; and when at length, towards the close of the history, her name is again introduced, it is only for the purpose of informing us that, on the arrival of the Israelites at Kadesh, in the desert of Zin, she died and was buried in that place. At the time of her death it is calculated she must have been nearly 130 years of age. Her decease preceded that of Aaron by about *four*, and that of Moses by about *eleven* months, so that these three distinguished members of the same family died within the same year.[3] Eusebius says her tomb was to be seen at Kadesh, near the city of Petra, even in his time.

MARY, *the mother of Jesus Christ*. Closely as this memorable female was connected with Him with whose person, character, and work the Scriptures are chiefly occupied, it is remarkable how slender is the information which they communicate to us respecting her; indeed it is only as her history serves to illustrate that of her son, that her name seems to be mentioned at all. From the genealogy furnished by St Luke, in the third chapter of his gospel, of our Lord's descent from Adam, we learn that her father's name was Heli, a descendant of David through his son Nathan. In that passage, indeed, it is her husband Joseph who was said to be the son of Heli; but that he was so only from his connection with her, and that it is her descent and not his that is given by St Luke, seems plain, for the following reasons: 1*st*, In the genealogy of Christ's descent furnished by St Matthew, we are informed that the father of Joseph was Jacob, and not Heli; 2*d*, The entire discrepancy of the genealogy as given by St Matthew from that given by St Luke suggests the conclusion, that, as both relate to Christ's descent, the one gives his descent by his reputed father's side, and the other by his mother's side; and, 3*d*, As the great object of furnishing these genealogies is to show that Christ was lineally descended from David, and as it was only through his mother that he was connected naturally with any of the human race, it is absolutely necessary that we should regard the genealogy of St Luke as that of his maternal descent, else we shall be left with two genealogies, neither of which serves the purpose for which one of them at least must have been intended. We conclude, therefore, that whilst the genealogy of St Matthew was designed to meet the prejudices of the Jews, for whom chiefly he wrote, by showing that even Joseph, whom they supposed to be the father of Jesus, was of royal descent, that of St Luke presents to us the real descent of Christ from his royal type and ancestor through his mother, and is accordingly to be regarded as giving us her descent as well as his.[4] This is confirmed by the passages adduced by Lightfoot (*Hor. Talm.* in loc.) from the Jewish writings, where Mary is expressly spoken of as the daughter of Heli.[5]

[5] The supposition that Mary was an heiress (ἐπικληρος), and was, according to the Mosaic law in reference to such cases, married by one

At the time the gospel history opens, Mary was the betrothed bride of Joseph, who, though like herself of royal descent, followed the humble occupation of a craftsman or artificer (τεκτων), probably, as our translators suppose, in wood. Among the Jews it was no uncommon thing for females to be thus betrothed for a very long time before they were married; and whenever this was the case, the parties were regarded as bound to each other by as solemn ties as if they had been really married.[1] Hence Joseph is called the *husband* of Mary, and she his *wife*, though as yet their contract of marriage had not been fulfilled (Matt. i. 19, 20). The wild opinion that these two terms are to be understood in their ordinary meaning, and that Joseph, when a very old man, had espoused Mary merely to protect her in the observance of a vow of perpetual virginity, rests only on the testimony of the apocryphal *Protevangelium Jacobi*, and is so plainly contradicted by the entire tenor of the sacred narrative, as to be unworthy of serious notice. Whilst thus in her virgin state, and as yet probably very young (for females were betrothed at a very early age amongst the Jews), Mary became the mother of our Lord. The circumstances attending this event are related with much simplicity and minuteness by the evangelist Luke. From his account we learn that an angel appeared to Mary at Nazareth, and saluted her as "highly favoured of Jehovah, blessed among women;" and when, startled by the suddenness of the apparition, and perplexed with the strangeness of his salutation, she began to be afraid, he calmed her anxiety by explicitly announcing to her the honour which was intended for her, in that she should be the mother of the promised seed, to whom should be given "the throne of his father David." Amazed at such an announcement, she asked, in all the simplicity of conscious innocence, "How shall this be, seeing I know not a man;" upon which the angel informed her that she was to become a mother by the miraculous power of God, and that therefore her child should be called the "Son of God." For the confirmation of this message, he further informed her that her cousin Elizabeth, then far advanced in life, had conceived a son, and that the event was nigh at hand, which should cause her reproach to cease amongst women; and having thus assured her that in her the long-cherished hopes of every mother and every maiden in Israel were to be realized, he left her meekly acquiescing in the will of God.

Her first impulse after this occurrence was to visit her cousin Elizabeth, of whose state the angel had informed her. The meeting of these pious and honoured females was one of mutual joy and congratulation; nor did they fail to mingle with their rejoicings grateful thanksgivings to the author of their privileges and blessings. After spending three months with her cousin, Mary returned to her former residence. Here a severe trial awaited her; for Joseph, perceiving her pregnancy, and of course ignorant of its true cause, regarded her as having broken her vows of betrothal to him. Unwilling, however, to expose her to the ignominy and danger[2] of a public disclosure of her crime, he had formed the resolution of putting her away privately, when information was communicated to him in a dream of the real nature of the case, and the command of God laid upon him to relinquish his intention of putting her away, and to take her to his home as his wife. This he accordingly did, and thus came to be regarded by his neighbours as the father of Jesus.

In ancient prophecy[3] it had been predicted that the Messiah should be born at Bethlehem, and the fulfilment of this prediction was brought about by an occurrence of a nature apparently purely accidental, and wholly independent of the purposes of his parents. This was the issuing of an edict by the Roman emperor, commanding a census to be taken of all the inhabitants of his dominions, and ordaining that the name of each should be enrolled in the chief city of the tribe or family to which he belonged. As Joseph and Mary were both of the lineage of David, this necessitated their going to Bethlehem, the city of David; and it was whilst they were there that the prophecy was fulfilled. Much disorder has been introduced into the gospel chronology from the confounding of the edict mentioned by St Luke with a subsequent decree imposing a tax upon the inhabitants of Judæa, and which led to serious strife and bloodshed whilst Quirinus was proconsul of Syria. The two, however, were perfectly distinct. The edict which brought Joseph and Mary to Bethlehem, though in our version it is said to have decreed "that all the world should be *taxed*," seems to have had reference merely to the taking of a census of the people, and of the amount of their property. The word used by Luke is ἀπογραφη, which is the classical word for a *census* or *enrolment*, whereas the proper word for *taxation* is ἀποτιμησις. That such edicts were frequently issued is well known to every classical reader; and though there is no express mention in any of the profane historians of any such being sent forth at the time referred to by St Luke, yet as it is not to be supposed that they have recorded *all* the events of this nature which occurred, their silence can hardly be regarded as a sufficient reason for rejecting the testimony of the evangelist.[4] To this confounding of these two distinct edicts, many have been led by the language of St Luke himself in the second verse, where it is stated (according to our version) that "this taxing was first made when Cyrenius was governor of Syria." Here the evangelist seems at first sight to have fallen into the mistake alluded to, and of this an eager use has been made by some of the enemies of Christianity to discredit his claims as an inspired historian. His words, however, when translated so as to give them a meaning (which can hardly be said to be the case in our version), seem rather designed to guard against such a mistake, than to indicate the

---

of her own tribe, who from that circumstance came to be called the son of her father, a supposition which was maintained at a very early age in the church, as we learn from Eusebius (*Hist. Eccl.* i. 7), is entirely arbitrary and unnecessary. See Crusii *Hypomnemata ad Theol. Proph.*, p. 355; and Olshausen's *Commentar*, Bd. i., seite 43; the latter of whom favours the hypothesis. Tradition assigns to the father of Mary the name of Joachim, and to her mother that of Anna. Dr Barrett thinks Heli may be found in Joachim, but by what etymological legerdemain this may be accomplished we cannot conjecture. In his prolegomena to the edition of the Gospel by Matthew, from the Dublin *Codex rescript.*, p. 44, he says,—"In hocce nomine Joachim latere nomen illud Eli, Luc. iii., 23, sive Eliakim, 2 Par. xxxvi. 4, vix dubitare potest." The confounding of Eli, Heb. עלי, with the Eli in Eliakim, Heb. אלי, says very little for Dr B.'s Hebrew scholarship.

[1] Deut. xxii. 23. "Femina ex quo desponsata est, licet nondum a viro cognita, est uxor viri; et si sponsus eam velit repudiare, oportet ut id faciat libello repudii." (Maimonides ap. *Buxtorf. de Divortio*, p. 76.)

[2] By the law of Moses such crimes were to be punished with death by stoning. (Deut. xxii. 23, 24.)

[3] Micah v. 2.

[4] The statement of Dio Cassius, which is supported by the testimony of Tacitus (*Annal.* i. 11), and of Suetonius (*Octav.* c. 101), that Augustus left behind him at his death a *breviarium* or *rationarium* of the Roman empire, in four volumes, of which the third *complectebatur quæ ad milites, quæque ad reditus sumptusque publicos, pertinebant*, renders it extremely probable that that monarch had taken much pains to have accurate returns made from all parts of his dominions. That this was the case, is indeed expressly stated by Cassiodorus, iii. 52. See also Suidas *in voc.* ἀπογραφη.

author's having fallen into it. According to a usage not uncommon in the New Testament, πρωτη seems to be used for πρωτερα;[1] and in this case the proper rendering would be, "this census took place *before* Cyrenius (or Quirinus) was governor of Syria;" a statement which seems thrown in parenthetically by the historian, for the purpose of informing his readers that the event to which he refers was not the famous and well-known taxing under Quirinus (commonly called, as he himself records in Acts v. 37, "*the* taxing," by way of eminence), but was antecedent to it.[2]

Owing to the multitudes of people whom this edict had brought together to Bethlehem, Joseph and his wife, on their arrival, found themselves unable to procure any better accommodation than what was afforded them by the stable of a public lodging-house. Here Mary was delivered of her first-born son, whom she herself swathed and laid in the manger. Amongst the busy crowd then assembled at Bethlehem this event excited no attention; but it was too important to be allowed to pass unregarded by Heaven, and accordingly an angel was commissioned to announce it to some pious shepherds that same night, as they were watching their flocks in the adjoining fields. Gladdened with the joyful news that the long-expected Messiah had at length appeared, these pious men lost no time in going to Bethlehem, that they might see the thing which had come to pass, and might offer their adoration to their infant Saviour. The intelligence they brought was received by Mary and Joseph with astonishment, and by the former carefully stored up in her remembrance. (Luke ii. 8-19.)

On the termination of the time appointed by the Mosaic law for the continuance of a woman's uncleanness after child-birth,[3] Mary went up to Jerusalem to present her son to the Lord, and to offer the sacrifice appointed in such cases.[4] These rites observed, she returned with her husband to their usual residence at Nazareth (Luke ii. 39). From this place they were in the habit of going up to Jerusalem every year at the feast of the passover (ver. 41); and it seems to have been on the occasion of one of these visits that the Magi from the East came with their offerings and adoration to Christ. The occurrence of this event is commonly regarded as having taken place immediately after the visit of the shepherds; but a comparison of the facts stated by St Matthew with those stated by St Luke forbids the entertaining of such a supposition. From the former we learn, that immediately on the visit of the Magi, Joseph and his wife fled into Egypt, where they abode till the death of Herod. But the latter informs us, that six weeks after the birth of Christ, he was taken up to the temple, and from thence carried down to Nazareth. From this it is plain that the visit of the Magi, and the consequent flight into Egypt, could not have taken place *before* the dedication in the temple, and must therefore be referred to a subsequent period.[5] It was on the occasion of another of these visits that the scene between Christ and the Jewish rabbis took place, when, after an absence from his parents of three days, he was found by his anxious mother sitting with the doctors in the temple, both hearing them and asking them questions (Luke ii. 42-52).

Some time before our Lord's entrance upon his public ministry, Mary seems to have lost her husband. This is rendered probable, not only from the circumstance that no mention is made after this period of Joseph in the gospel history, but also from the freedom with which Mary appears to have moved from place to place; a freedom hardly consistent with her duties as a wife whose husband was still alive. As confirmatory of this it may be mentioned, that it was admitted as an acknowledged fact in the early ages of the church, that she supported herself by weaving; and hence Celsus calls her Χερνητις, and Tertullian *Quæstuaria*. Her residence seems to have been principally at Capernaum, on which account probably this place was called Christ's "own city" (Mat. ix. 1), as her house would be the place to which he would naturally retire during the intervals of his public labours. She is mentioned as having been present at the marriage at Cana in Galilee, where he commenced his miraculous works by turning water into wine (John ii. 1). Shortly after this, whilst he was teaching in the synagogue at Capernaum, she endeavoured to induce him to desist, fearing probably lest he should offend the people by his pointed rebukes; but he resisted her entreaties, declaring that no earthly connections could be so dear to him as those spiritual unions which he sought to form by the truths he was teaching. On the occasion of his going up to Jerusalem for the last time before his death, she was one of those who accompanied him; she followed him to Calvary, beheld him elevated on the cross, and retired not until she saw him expire. As she stood gazing on him, along with some of his followers, he commended her to the care of his beloved disciple John, who from that time took her to reside in his own house. We learn from Acts i. 14, that she was amongst the disciples at Jerusalem when they were waiting for the gift of the Holy Spirit. An uncertain tradition informs us that she removed with John to Ephesus when he went to reside there, and died and was buried in that place. Other accounts state that she died and was buried at Jerusalem, which is perhaps the more probable statement of the two. By the Roman Catholic church the Virgin Mary has been deemed worthy of divine honours, and has even been made to occupy a more prominent place in the devotions of the people than the Saviour himself.[6] Such reverence for the Virgin was unknown in the early ages of the church, but the way was gradually paved for it by the importance which was attached to discussions respecting her in the writings of the Fathers, and by the extravagant terms of eulogy in which they spoke and wrote regarding her. From styling her θεοτοκος, θεομητηρ, δεσποινα ἁγια και ἀειπαρθενος, as even Chrysostom writes of her; from speaking of her as "the sacred treasure of the universe, the quenchless lamp, the crown of virginity, the sceptre of orthodoxy, the temple indestructible, the tenement of the infinite, both a virgin and a mother," as Cyril of Alexandria describes her,[7] the transition was not difficult to the offering of divine homage to the object of such unwarranted eulogium. Mr Newman, in his *Essay on the Development of Christian Doctrine*, p. 50, adduces the growth of "the doctrine of the θεοτοκος, or Mother of God, into *hyperdulia*," as one of the instances of what he calls "moral developments;" that is, developments that "are not proper matter for controversy, but are natural and personal, substituting what is congruous, desirable, pious, decorous, generous, for strictly logical inference." Of the utter absence of all logical strictness from the process of this "development" there can be little doubt; but whether the result merits the laudatory epithets Mr Newman has heaped together must be questioned. To most people the process will appear rather as affording a striking illustration of the tendency of all religious error to become more and more gross, and to carry those who embrace it still farther and farther into delusion. The first step was to declare the perpetual virginity of Mary, which was done about the middle of the fourth century. Then came conjectures about her miraculous transit from earth to heaven, which gradually led to a belief in her assumption. Next, Radbert in the ninth century propounded the belief that Mary bore her son " Omnino clauso utere . . . sine dolore, et sine gemitu," a dogma which, however, was opposed at the time by Ratramn. About the same time festivals were appointed in celebration of her birth and of her ascension. In the tenth century men began to pray to her and to worship her; Saturday was dedicated to her, and an office of the " Holy Mary" appointed to be used. In 1140 the doctrine of the immaculate conception of Mary began to be taught, though not without strenuous opposition on the part of many, among whom St Bernard was the most conspicuous. This dogma became soon afterwards a bone of contention between the Dominicans and the Franciscans,—the former of whom, following Thomas Aquinas, opposed it; while the latter, following Duns Scotus, defended it. Two new festivals were instituted in honour of Mary,—the festival of the "Presentation," appointed by Pope Gregory IX. in 1372; and the festival of the " Visitation," appointed by Pope Urban VI. in 1389. In 1387 a great advantage was gained by the advocates of the immaculate conception, in consequence of a decision of the university of Paris, that all who graduated in it should assent to a condemnation pronounced by the university on all who should decidedly reject this doctrine,—a decision which speedily assumed the character of a positive declaration in favour of it. In 1439 a council held at Basle decreed that the doctrine of Mary's conception without sin, and her immunity from actual sin, was to be embraced by all Catholics,— " Tanquam piam et consonam cultui ecclesiastico, fidei catholicæ, rectæ rationi et sacræ Scripturæ." Other universities followed the example of that of Paris; the mendicant orders became zealous preachers of the doctrine; miraculous legends concerning her, such as that of the conveyance of her house from Nazareth to Loretto, where it was set up as a shrine dedicated to her, were plentifully circulated; and a great impulse was everywhere given to the worship of the Virgin, as the being " by whose dispensation alone any creature could obtain any grace or virtue from God." Art lent its aid to the strengthening of this cause, and pictures of the Blessed Virgin, from the highest style which painting has reached, down to the coarsest daubs, kept continually before the minds of the people the leading facts of her history as taught by the church, and the pretensions which the church had set up in her behalf. By these means her worship was successfully established; her name was invested with every attribute of glory and majesty; she was hailed as the Mother of Mercy, the Queen of Heaven, the Fulgid Gate of Heaven, and such like epithets; prayers were offered to her for the highest blessings; and she gradually ascended in the view of all good Catholics, until her glories obscured those of her Son, and the place due only to Him came to be assigned to her. Her image is now in every Roman Catholic church, and in every house where a Roman Catholic dwells. At corners of streets, and where roads cross, chapels are erected to her honour, adorned with flowers, and illuminated with tapers, and round which, at the hours of vespers, multitudes may be seen kneeling in prayer. Her image is worn as an amulet on the breast, or woven into chaplets for the head; and even on the uniform of the pope's scudieri the Madonna and Child figure as the appropriate badge of their office.[1] The present pope has put the colophon on this extended volume of blasphemy and folly, by authoritatively declaring (in 1855) the immaculate conception of the Virgin to be a doctrine of the Catholic church. It is to be regretted that, even by Protestant writers, a degree of importance has been attached to inquiries respecting her, which nothing in Scripture would seem to authorize. How many, for instance, have contended for her perpetual virginity, as if it were a matter on which the whole of our religion depended. Such matters, however, " do not affect," as the great Basil truly remarks, " the doctrine of godliness; for though until the birth of Christ her virginity was necessary, what happened afterwards is a matter not worthy of anxious inquiry."[2] A more interesting question is that respecting the fact of her having had any children by Joseph after the birth of Christ, because upon the answer given to this depends the meaning which we are to attach to those passages that speak of our Lord's " brethren and sisters." On this different opinions have been entertained:—1. That these appellations are to be taken according to Hebrew usage, as merely signifying *near relations*;[3] 2. That they designate the children of Joseph by a previous marriage; 3. That the parties so designated were really the children of Mary and Joseph, and so the german brothers and sisters of our Lord according to the flesh. What renders this last opinion the most probable is, that Jesus is called Mary's πρωτοτοκος, or first-born; and that Matthew, in connection with this, is careful to state that Joseph knew her not *until* (ἕως) she had brought forth her first-born son. This would seem to imply that she had other children afterwards by him. This view is also the most natural in such passages as Matt. xiii. 55; Mark iii. 31; Luke viii. 21; John ii. 12; vii. 3, where the brethren of Christ are mentioned in connection with Mary. " It would be very forced work," to use the words of Neander, "to suppose that in all these passages ἀδελφοί is placed for ἀνεψιοί."[4]

MARY *Magdalene*, so called apparently from *Magdala*, a castle, and probably also a village, near Gamala and the baths of Tiberius, on the eastern shore of the sea of Galilee (Matt. xv. 39).[5] This was in all probability her birthplace, and from it she was named, to distinguish her from the other Marys who followed Christ. She has been often confounded with Mary the sister of Martha and Lazarus, and also with the " woman who was a sinner," mentioned in Luke vii. 36, &c., but in both cases without any sufficient reason. Equally unfounded is the notion, that before her conversion she was a person of abandoned character; a notion which, though resting on no better authority than that of some monkish legends, has nevertheless become so generally received, that few even in Protestant countries ever think of questioning its accuracy. The only passage of Scripture, however, that can be quoted as favouring this opinion, is that in which it is said that " out of her went seven devils" (Luke viii.). But this cannot be admitted as evidence in support of the point in question; for, whatever may be the conclusion to which we come as to the nature of that diabolical possession which prevailed in the days of our Lord, one thing is certain in regard to it, which is, that to be afflicted with it did not imply in the individual so visited any peculiar moral depravity; so that, though the case of Mary Magdalene was one of unusual severity (the number *seven* being the number of completeness), it by no means follows from this that she was not a virtuous, nay, pious female. On the contrary, the evidence from Scripture seems rather to favour the supposition that she was a person at once of blameless character and respectable station. She is introduced to us for the first time in the society of Joanna, the wife of Chuza, steward of Herod's household (ἐπίτροπος, *præfectus domus*), with whom she was associated in ministering to the wants of our Saviour "out of their substance" (ὑπάρχοντα, *opes facultates*); and from the language used by Mark (ch. xv. 41), it would seem as if this had been the usual practice of these pious females whenever he paid a visit to Galilee. Had she been, as is commonly supposed, a mere common prostitute before her conversion, it is difficult to understand how she should either associate with persons of such rank as Joanna, or be possessed of the means of such liberality towards Christ.[1]

On the occasion of our Lord's going up to Jerusalem from Galilee, immediately before his death, Mary Magdalene was one of those by whom he was followed; nor does she seem to have left him as long as he continued upon earth. She was one of those who beheld him from a distance when he was hanging upon the cross (Mark xv. 40); and when he was taken down and buried, it was she and Mary Salome who sat over against the sepulchre and beheld where he was laid (Matt. xxvii. 61; Mark xv. 47). From the sepulchre she returned with her companion into the city to procure materials for embalming his body; and having rested on the Sabbath, they came at the dawn of the third day to perform this office of respect to their departed Lord. Contrary to their expectations and fears, they found the stone which they had seen placed upon the mouth of the tomb rolled away, and free entrance afforded to its interior. Stooping down and looking in, they were startled to find the body of Jesus gone; but as they wondered, an angel appeared, who informed them of his resurrection, and at the same time commanded them to carry the tidings of this event to the rest of the disciples (Matt. xxviii. 7). Amazed and perplexed, they fled from the sepulchre, and announced to their company what they had seen; upon which Peter and John hastened to satisfy themselves of the correctness of their report, by returning with them to the place where Jesus had been interred. When the others returned home, Mary seems to have remained by the empty sepulchre to weep; and "as she wept," we are told, "she stooped down and looked into the sepulchre, and seeth two angels sitting, the one at the head and the other at the feet, where the body of Jesus had lain." By them she was asked the cause of her tears; to which she answered, that it was because they had taken away her Lord, and she knew not where they had laid him. During this conversation, Jesus himself drew near and addressed her; but, stupified with grief, she did not at first recognise his voice, and, intent upon gazing into the sepulchre, she answered his inquiries as to what she wept for, and what she sought, without turning herself, under the impression that he was the gardener. To recal her recollection, Jesus addressed her by name; upon which she immediately recognised the well-known voice, and turning herself, exclaimed, "Rabboni, which is to say, Master." After a brief conversation, he sent her to announce to the disciples that she had seen him, and that he was about to ascend to heaven. This command she obeyed; and from this time forward we find no mention made of her in the New Testament. As to certain traditionary accounts of subsequent actions and journeyings in which she is said to have been engaged, they bear too obviously the marks of mere legendary fiction to be worthy of notice.

Mary, *the sister of Martha and Lazarus.* These three individuals composed the members of a family, than which none was more beloved and honoured by our Lord in the days of his flesh. Their residence was at Bethany, a village not far from Jerusalem, where Martha seems to have been a householder; and thither our Lord was in the habit, apparently, of frequently retiring during the intervals of his public labours. The name of Mary is first introduced, in connection with that of her sister, in the account given of a visit paid by Christ to their abode, during one of his journeys; on which occasion, whilst Martha busied herself in caring for the hospitable entertainment of her guest, Mary sat at his feet to receive his instruction (Luke x. 38, &c.). The next mention that is made of her is in the touching and striking account given by John (ch. xi. 1–46) of the death and resurrection of Lazarus; and she appears for the last time shortly subsequent to this, on the occasion of an entertainment given to our Lord, a few days before his crucifixion, by Martha, when she anointed his feet with precious ointment, and wiped them with the hair of her head (John xii. 1-9).

Mary, *the mother of James and Joses, and Simon and Judas.* She is the same who is elsewhere called the wife of Cleophas (John xix. 25), or Alphæus, these two being only different modes of Grecizing the Hebrew חלפי, *Chalpai.* The common opinion is that she was the sister of the Virgin Mary, an opinion founded on John xix. 25. But as it is not very probable that there would be two sisters in one family of the same name, it seems better to adopt the suggestion of Wieseler (*Theol. Studien und Kritiken*, 1840, p. 648), that in this passage *four* persons are enumerated—Mary, Mary's sister (whose name is not given), Mary the wife of Cleophas, and Mary of Magdala.

Mary, *the mother of John Mark.* (Acts xii. 12.)

Mary, a pious member of the church at Rome. (Rom. xvi. 6.) (W. L. A.)

Mary I., *Queen of England*, was the daughter of Henry VIII. and Catherine of Aragon, and was born on the 18th of February 1516. She ascended the throne on the 6th of July 1553, married Philip II. of Spain on the 25th of July 1554, and died on the 17th of November 1558. (See England.)

Mary, *wife of William III.*, was the eldest daughter of James II. and Ann Hyde, and was born in 1662. She married the Prince of Orange in 1677, shared the throne with her husband in 1688, and died in 1694. (See Britain.)

Mary, *Queen of Scots*, was the daughter of James V. of Scotland and Mary of Lorraine, and was born on the 8th of December 1542. She married the Dauphin of France, afterwards Francis II., on the 24th of April 1558; assumed the personal government of Scotland on the 19th of August 1561; married Lord Darnley on the 29th of July 1566, and Bothwell, on the 15th of May 1567; was forced to retire from the throne on the 17th of June 1567; was imprisoned by Elizabeth in 1568, where she remained till her execution on the 8th of February 1587. (See Scotland.)

MARYBOROUGH, a town of Ireland, capital of Queen's county, is situated on a small tributary of the Barrow, 50 miles S.W. of Dublin. It is straggling and meanly built, consisting chiefly of one long irregular street on the Dublin and Limerick road. It has, however, several good public buildings, among which are,—the parish church, a Roman Catholic chapel, several Dissenting chapels, court-house and prison, barracks, infirmary, and lunatic asylum. It returned two members to the Irish parliament till the Union, when it was disfranchised. Pop. (1851) 2079.

---

[1] For a complete investigation of this point, see Lardner's Letter to Jonas Hanway, Esq., *Works*, vol. v., 4to. ed. See also Macknight's *Harmony*, sect. 43.

MARYLAND, one of the United States of North America, bounded on the N. by Pennsylvania, E. by Delaware and the Atlantic, and S. and W. by Virginia, from which it is separated by the River Potomac; and extending from 38. to 39. 44. N. Lat., and from 75. 10. to 79. 20. W. Long. Its form is very irregular; its greatest length is 190, and its greatest breadth 120 miles; area 9356 square miles. The surface of Maryland may be regarded as consisting of two distinct parts. The one comprehends the high lands in the W. of the state, traversed by several ridges of the Alleghany Mountains, and extending in a narrow strip of land eastward as far as the lower falls of the rivers. The other portion, which is low and flat, is subdivided into two parts by Chesapeake Bay. These are called respectively the Western and the Eastern Shore; the former consisting of a peninsula formed by the estuary of the Potomac and Chesapeake Bay, and the latter of part of that peninsula lying between Chesapeake Bay and the Atlantic. Of this last, the north-eastern part is occupied by the state of Delaware, while the southern extremity belongs to that of Virginia. In the mountainous district the principal ridges are South-East Mountain or Parr's Ridge, terminating at Sugar-Loaf Mountain on the Potomac. In a direction nearly parallel to this range, extends Catoctin Mountain, reaching the river at the Point of Rocks. Further up, the river is crossed at Harper's Ferry by the Blue Ridge or South Mountain, and at Hancock by the Kittatinny. In the extreme W. of the state rise the main ridges of the Alleghany Mountains, besides Rugged Mountain, Wills Mountain, and other detached chains. None of these ridges have any great elevation; and the valleys which lie between them are remarkable for the fertility of their soil and the mildness of their climate. The eastern and western shores of the state are very similar to each other in soil and productions. The soil is alluvial, and consists in general of a mixture of sand and clay; and though not very fertile by nature, is easily rendered productive by the use of manure, which is supplied in large quantities by the marl beds in the country. The climate is temperate, and in general salubrious, with the exception of some of the low-lying country near Chesapeake Bay, from which rise noxious exhalations, especially during the months of autumn. The principle feature in this part of the state is the Bay of Chesapeake which divides the whole region into two parts from N. to S., and gives the outline of the state a very irregular appearance. This great estuary has a total length of 180 miles, of which 120 are in this state, and a breadth varying at different places from 7 to 20 miles. It is navigable for the largest vessels throughout its entire length, and it abounds in fine fish and oysters. It receives many rivers of various sizes, and its coasts are deeply indented by numerous bays and creeks. The surface of the bay is studded with many islands, the most considerable of which is Kent Island, opposite the city of Annapolis, about 12 miles in length. The Potomac River, the largest of those that fall into Chesapeake Bay, and which forms the boundary between this state and that of Virginia, rises in the Alleghany Mountains, and flows in an irregular course, first nearly E. and afterwards S. and S.E., till it enters the Bay of Chesapeake towards its southern extremity between Point Look-out and Smith's Point. Its width at its mouth is 7½ miles, and it is navigable for the largest vessels as far up as Alexandria; while by means of canals the falls which occur not far above this are avoided, and the river rendered navigable for boats as far as Cumberland, 191 miles above Washington. The scenery of this river is very fine, especially at these falls, which, though not very high, are among the most interesting objects of the kind in the States; and at Harper's Ferry, where the river rushes through a defile in the Blue Mountains. The principal affluents of the Potomac in this state are the Monocacy River, Antietam and Conecocheague Creeks. Besides these are,—the Patuxent, which flows in a direction nearly the same as the Potomac, rising in Parr's Ridge, and falling into Chesapeake Bay, and is navigable as far as Nottingham, 50 miles up; the Patapsco, falling into the bay near Baltimore; the Susquehanna, which is for the greater part of its course a Pennsylvanian river, but which falls into Chesapeake Bay in this state. The Elk, Chester, Choptank, Nanticoke, and Pocomoke, all flow to the eastern shore, and are navigable for 30 or 40 miles. The only river in Maryland which does not flow into Chesapeake Bay is the Youghiogeny, which rises in the mountains of the extreme W., and flows northwards into the Ohio. In a geological point of view, the whole of the level region of Maryland consists of recent formations, containing many interesting fossils; while the mountain district consists of metamorphic strata, such as gneiss and mica, slate, granite, limestone, &c.; and is rich in coal and iron mines. Maryland contains a considerable extent of forest land; the principal trees are,—oak, pine, chestnut, cedar, ash, beech, poplar, and elm. The principal agricultural productions of this fertile and well-cultivated district are tobacco, wheat, and Indian corn; besides which large quantities of oats, rye, flax, hay, potatoes, peas, beans, &c., are raised. The number of farms in the state in 1850 was 21,860, comprising 2,797,905 acres of cultivated land; and the total value of the farms, with their machinery and implements, was L.18,676,233. The live stock in the same year included 75,684 horses, 219,586 head of cattle, and 177,902 sheep; and amounted in total value to L.1,166,174. In the agricultural produce for the year ending June 1, 1850, the principal items are the following:—Wheat, 4,494,680 bushels; rye, 226,014 bushels; Indian corn, 10,749,858 bushels; oats, 2,242,151 bushels; tobacco, 21,407,497 lb.; potatoes, 973,932 bushels; and butter, 3,806,160 lb. In the aggregate amount of tobacco produced, Maryland is the third of the States; and in comparison with the population, the second. The manufactures of Maryland are numerous and important. There were, in 1850, 24 cotton factories, employing 3022 hands, and producing stuffs to the value of L.441,772; 38 woollen factories, employing 362 hands, and producing stuffs to the value of L.61,488; 51 furnaces, forges, &c., employing 2699 hands, and producing 59,855 tons, valued at L.523,519; and 116 tanneries, producing leather to the value of L.229,820. Total number of manufactories in the state (1850), 3863; capital invested, L.3,073,588; hands employed, 30,124; value of raw material, fuel, &c., L.3,609,738; value of produce, L.6,870,355. The improvements in the internal communications of this state have been very extensive, and Maryland has in this department displayed more energy and enterprise than caution and prudence. There are three extensive canals—the Chesapeake and Ohio Canal, which has only been completed as far as Cumberland, a distance of 200 miles from its commencement at Alexandria, and which cost up to the year 1839 more than L.145,833; the Susquehanna Canal, communicating with the interior of Pennsylvania; and the Chesapeake and Delaware Canal, which affords a water-communication with Philadelphia. There are also many railways in the state. Of these the Baltimore and Ohio, and the Baltimore and Susquehanna lines, with their several branches, are the principal, and have a total length of 514 miles.

The commerce of Maryland is very great, owing to the

Maryland.

facilities for trade afforded by its excellent harbours, its navigable rivers, canals, and railways. The principal articles of export are,—flour, wheat, pork, and tobacco; and the total value of goods exported from the state in 1850 was L.1,451,533. The imports for the same year amounted in value to L.1,275,886. For the year ending June 30, 1855, the respective values were,—exports, L.2,165,413; imports, L.1,623,781.

The number of vessels built in the state in the year ending June 30, 1855, was 122, with a tonnage of 22,524. Fishing is carried on in Chesapeake Bay, and large quantities of fish are taken, consisting principally of herring, shad, eels, perch, mullet, &c.

The state of Maryland is divided into 21 counties; and the principal towns are,—Baltimore, Cumberland, Frederick, Hagerstown, and Annapolis. Though not the largest town, Annapolis is the capital of the state. The present government of Maryland, which was settled by the constitution of 1851, consists of a Governor, elected for four years, with a salary of L.750 a-year; a Senate of 22 members, also elected for four years; and a House of Representatives of 74 members, elected for two years. There are three districts in the state, from each of which in rotation the governor must be chosen. The franchise extends to every white male above the age of twenty-one, a citizen of the United States, and who has resided for a year in the state, and six months in the county or town for which he votes. The qualifications for members of the legislature are, that they shall be not less than twenty-five years of age for the Senate and twenty-one for the House of Representatives, and have resided three years in the state and one in the district for which they are elected. The judicial establishment consists of an orphans' court in each county, composed of three judges, elected by the people for four years; eight circuit courts, each presided over by a judge elected for ten years; and a court of appeal, with four judges elected from as many districts for ten years, one of whom is appointed chief justice by the governor and Senate. Judges must retire at the age of seventy. The religious institutions in Maryland consist of an aggregate of 909 churches, with property amounting to L.822,476. The proportions of places of worship belonging to the different sects are as follows:—Baptists, 48; Episcopalians, 133; Friends, 26; German Reformed, 22; Lutherans, 42; Methodists, 479; Moravians, 12; Presbyterians, 57; Roman Catholics, 65; Union Church, 10; minor sects, 10. The educational establishments consisted in 1850 of 11 colleges, with 91 teachers and 992 students; 907 public schools, with 1005 teachers and 33,254 scholars; and 224 academies and other schools, with 489 teachers and 10,677 scholars. The total number attending school in the state in 1850 was 62,063; and the number of adults unable to read or write was 41,877. The amount of the public funds expended for purposes of education was in the same year L.15,862; and the amount raised by taxation was L.18,055. The principal public institutions in the state are at Baltimore, and consist of a state penitentiary, a lunatic asylum, &c. The amount of the state debt of Maryland, September 30, 1856, was L.3,114,498; the total receipts for the year ending at that date, L.256,359; and the total expenditure for the same year, L.256,356.

The earliest settlement of Europeans in the territory of this state was in 1631, when William Claiborne founded a colony on Kent Island.

The district was named Maryland from Henrietta Maria, queen of Charles I., who granted a charter for the territory to Lord Baltimore, a Roman Catholic, in 1632. A colony, composed chiefly of Roman Catholics, fugitives from religious persecution, settled at St Mary's in 1634 under Leonard Calvert, brother of Lord Baltimore. The government was liberal and democratic, the legislative functions being exercised by the lord proprietary and the representatives of the people. A contest, however, soon arose between the governor and the people about their respective rights in the legislature; the former endeavoured to force on the colony a system of laws framed by himself, and the latter resisted this attempt, restricting his power to a right of veto on any measure passed by the people. The governor ultimately gave way, and the constitution of the colony became of a more popular character. During the time of the civil war in England, the governor, a Catholic, and an adherent of the king's, expelled from the colony a number of Puritans, who settled in Virginia, but afterwards returned, and attempted to gain the supremacy in Maryland. After partial successes on both sides, the legislature passed in 1649 an Act of Toleration, in which Catholics, Quakers, and Puritans, who had now all in turn experienced the evils of persecution, had a share. Soon afterwards the adherents of the Commonwealth, which was now in power in England, having gained the upper hand in the colony, and reinforcements having been sent to their assistance, the lord proprietary was overthrown, but not until after a bloody battle. After the restoration of Charles II., the government was restored to the Baltimore family, with whom it continued till the Revolution of 1688. After that event the affairs of the colony were managed by governors appointed by the crown, until 1715, when Benedict Leonard Calvert, the heir of the Baltimore family, who had embraced the Protestant religion, was reinstalled as governor of the colony. After this period Maryland continued to make progress in population and manufacturing industry, though the policy of Great Britain, which was calculated to repress the progress of the colony, was felt as a great hinderance. Long and tedious disputes were carried on between Maryland and Pennsylvania, which were only finally settled in 1785, when the frontiers were adjusted as they at present stand. No remarkable engagement took place here in the revolutionary war; but Annapolis was the scene of some of the meetings of the Congress and of Washington's resignation of the command at the end of the war.

Maryland is a slave-holding state; and though after the Revolution there was a strong tendency to emancipation, all public measures of that kind were checked by an article in the constitution of 1836.

Population in 1850.

	Male.	Female.	Total.
Whites	211,187	206,756	417,943
Free Coloured	35,192	39,531	74,723
Slaves	45,944	44,424	90,368
Total	292,323	290,711	583,034

Maryport.

MARYPORT, a seaport and market-town of England, county of Cumberland, is situated near the mouth of the Ellen, 29 miles S.W. of Carlisle. The town is neat and well built, and has entirely risen within the last century. The only public buildings of importance are the town-hall, the market-house, and the bridewell, which are elegant edifices. Maryport has a chapel of ease, and places of worship for Presbyterians, Methodists, Independents, Baptists, Quakers, and Roman Catholics. The town has also national and British schools, a mechanics' institution, a reading-room and library, and a savings-bank. The inhabitants are principally employed in ship-building, and the manufacture of sail-cloth, ropes, cordage, and other articles for ships. The trade of the place is very considerable, consisting chiefly in coal, which is conveyed through Maryport from Northumberland and Durham to Scotland and Ireland. In 1855 283,603 tons were shipped here. Coke, lime, and stone are also exported; and the imports consist of cattle, timber, flax, and iron. The harbour is dry at low water. A steamer plies between this town and Liverpool, the Isle of Man, and Dublin, every week in summer, and every fortnight in winter. The town had in 1855, 105 vessels, of 15,987 tons burden; and during that year the number of vessels that entered the harbour was 273, with a tonnage of 39,052; and of those that left, 2654, with a tonnage of 229,658. The market-day is Friday; and fairs are held twice a-year. Pop. of the chapelry (1851), 5698.

MARYSVILLE, a post-town, capital of the county of Yuba, in the state of California, North America, is situated on the right bank of the River Yuba, about a mile above its confluence with the Feather River, and 100 miles N.N.E. of Benicia. Steamers ply regularly between Marysville and San Francisco, touching at Sacramento. Pop. (1853) 8000.

MASACCIO, a celebrated painter of the Florentine school, was born in 1402 at San Giovanni in the Valdarno. His real name was Tommaso Guidi, but his unfitness for the cares of ordinary life procured for him at an early age the nickname of Masaccio, or "Helpless Tom." Receiving the first lessons in his art from Masolino da Panicale, he was employed under that master in painting the Brancacci chapel in the church of the Carmine at Florence. He also carefully studied the sculptures of Ghiberti and Donatello, and learned perspective from Brunelleschi. About 1430 Masaccio seems to have visited Rome, and there, according to Vasari, he was employed in the execution of several important works. On the return, however, of his patron, Cosmo de' Medici, from exile in 1434, he went back to Florence, and was engaged to complete the paintings of the Brancacci, left unfinished by the death of his old master Masolino. He died, however, in 1443, before he had fulfilled his engagement. The suddenness of his death, and the envy in which he was known to be held by his rivals, combined to originate the suspicion that he had been poisoned.

Ever working with a clear perception that painting is simply a close imitation of nature, Masaccio surpassed all his contemporaries in the easy postures of his figures, in the simplicity and dignity of his draperies, and in his natural and harmonious colouring. So unprecedented was his skill in foreshortening, and his knowledge of perspective, that he may be said to have introduced a new era in the annals of painting. The frescoes in the church of the Carmine at Florence were his masterpieces, and were zealously studied by Raphael and other great painters of the fifteenth and sixteenth centuries. In his epitaph, written by Annibal Cavo, it is said that Michael Angelo was the teacher of other painters, but the pupil of Masaccio.

MASANIELLO, the abbreviated name commonly given to TOMMASO ANIELLO, a fisherman born at Amalfi in 1622, who, at the age of twenty-five, became chief of the celebrated revolution in Naples which bears his name. While under Spanish dominion that country was subjected to the greatest misgovernment. The ambition of Philip III. and Philip IV., both of whom required extraordinary funds to carry on the wars of Lombardy and Catalonia, scarcely surpassed the avidity and selfishness of the exacting viceroys employed by them to plunder the Neapolitans. A confused and embarrassed administration; a corrupt magistracy; venal employées who enriched themselves as a reward for other services; an oppressive distribution of taxes, which rendered a system of violence necessary in levying them; a ready compliance with all the arbitrary acts of the nobility, who set the law at defiance and enjoyed a total immunity from all burdens of the state; and last, though not least, an organized system of brigandage, which the government was as powerless and unwilling to check as the nobles were interested in upholding;—such was Naples under the viceregal government of Spain. This state of things, long hateful to the Neapolitan people, reached its height under his excellency the Viceroy Ponce de Léon, Duke d'Arcos. Taxes were multiplied, more especially on the articles of daily consumption; and in 1647 even fruit, which in summer forms almost the only food of a large portion of the populace, did not escape this galling impost. Fish had been taxed a few years before; and the young Masaniello, accustomed, in the exercise of his calling, to dispute with the tax collectors, had, from his fearless dealing with these universally hated functionaries, become a favourite with his own class and with the common people in general. One day when his wife, detected with contraband flour, was imprisoned and fined, he assembled a number of young men, armed them with sticks, and urged them to take advantage of the crowds at the approaching festival of the Madonna del Carmine to make a solemn and public protest against these oppressive taxes. On the 7th of July, however, some country people coming as usual to Naples to sell fruit, were compelled by the tax collectors to pay the duty beforehand. The market people revolted, and one of them, trampling the fruit under his feet, cried out indignantly that he would rather destroy his fruit than submit to such exaction. A crowd assembled, partly from curiosity, anger ensued, and the companions of Masaniello fanned the flame which soon burst forth. The agitation increased by degrees until it became general. The officials, who had prudently retreated, were now panic-struck; still the insurrection wanted a chief, and Masaniello resolved at once to seize the opportunity. He made his way among the crowd, and with a voice that drowned all other sounds, cried, "Away with the tax on fruit! death to bad rulers!" "Away with them!" shouted the multitude; "Long live Masaniello!" In a moment the infuriated mob drove off the functionaries, who were looking on in mute astonishment, burned the tax-collectors' offices, and proceeded to the royal palace to besiege the viceroy, who had, however, already taken refuge in the Castel Nuovo. The people must vent their rage on something; so Masaniello directed that the houses of the nobility should be burned, but threatened death to any who should attempt to abstract a single object from the flames. This order was blindly obeyed. The prisons were thrown open, and one Perrone, who afterwards became Masaniello's evil genius, was set at liberty, together with all the thieves and malefactors of the town. The viceroy sent a messenger, who promised everything; but Masaniello, not satisfied with simple promises, demanded the charter granted by Charles V. prohibiting the imposition of new taxes, except by a special decree from the king. A hundred thousand men were now at the command of the intrepid fisherman, whom they followed and promptly obeyed. A perambulating throne or platform was erected, consisting of a rough high-raised dais, placed on a waggon drawn by four strong horses. On this he sat, sword in hand, the red cap of the fisherman on his head, and dressed in the mean garb of his calling. This simplicity increased the enthusiasm of his followers, and Masaniello found himself the animating soul of thousands. The Cardinal Filomarini, Archbishop of Naples, came as a mediator from the viceroy, and was received with marks of respect. Hopes were entertained that the insurrection would be checked, when the nobles, headed by the Duke of Monteleone, and his brother Prince Caraffa, assembled 200 brigands, and charged them to assassinate Masaniello. Two hundred shots were fired at him while seated on his throne, but, by an extraordinary chance, not one reached him. This inflamed the popular fervour to a degree of fanaticism, while superstition and ignorance were ready with their marvellous explanations. The assassins were seized and executed. None were spared,—not even those who denounced their instigators. Two hundred heads, fixed on poles, now bristled round the throne-like erection on which Masaniello, the people's idol, sat. The two noblemen were pursued, but the duke made his escape; while the prince, having fallen into the hands of the mob, was beheaded and quartered; his head, bearing the inscription "*Giuseppe Caraffa ribelle e traditore della patria*," being placed conspicuously among the others. Judicial, regal, administrative powers were all now centred in Masaniello's absolute and single hand. He ordered the nobles to be disarmed, and the people to receive each man a sword, a musket, ample ammunition, and provisions. He established a police, and decreed that all judgments should be referred to him, on which he gave prompt and impartial verdicts.

At last, through the intervention of the Archbishop of Naples, he consented to treat with the viceroy. He now began to despise his red cap and fisherman's dress, and assumed a gaudy attire glittering with silver and gold. The people were amazed when they saw him, thus adorned, head a cavalcade, equally splendid, on his way to the church of the Madonna del Carmine to negotiate a treaty with the viceroy. He styled himself "Capo del Popolo," and with this attribute he altered, modified, and rescinded, as he thought proper; none daring to oppose him. Finally the principal terms were settled:—*1st*, The total abolition of all the taxes imposed since the time of Charles V.; *2d*, Absolute equality of political rights among all classes of citizens; *3d*, General amnesty to all who had taken part in the insurrection; *4th*, That the Neapolitan people should remain armed till the ratification of the treaty by his Catholic Majesty the King of Spain. He then exacted an oath from the Duke d'Arcos, and turning to the people, declared his mission accomplished, his desires fulfilled, and that henceforth he would follow his trade as a fisherman. Having said these words, he threw off his rich attire, fell at the feet of the viceroy, professed allegiance to the king, love to the people, devotion to his country, and rejected all proffered rewards. This imposing scene called forth the deafening shouts of the multitude that thronged the church, who begged him to retain the authority he had for several days exercised so successfully. The Duke d'Arcos showed him the greatest respect, praised his skill in statesmanship, and, to celebrate the restoration of peace, invited him to a solemn banquet at the royal palace. Masaniello's star now began to wane. His conduct at the banquet was boastful and extravagant, some say showing signs of an unsound mind, caused by overjoy at his success, or, as other historians affirm, by a poisoned drink given him by the viceroy. Masaniello, now arrogant, overbearing, and arbitrary to his fellows, lost that simplicity which had made him their idol. At the close of the fourth day of his power, two hundred thousand men would have given their life for him; on the eighth day there were as many disaffected. The Duke d'Arcos, who had been plotting to bring about this state of things, seeing the moment had now arrived to get rid of the spirited tribune without danger to himself, on the 16th of July placed four men in ambush. They fired upon the unfortunate leader, who fell down dead. Hated as much as he had been loved, his body was insulted even by his old friends. The hired assassins, emboldened by this feeling, showed their zeal by severing his head from his body, and holding it by the hair, presented it to the viceroy, who ordered it to be thrown into the castle moat. One day, however, had scarcely passed when a more natural feeling returned. The greater part of the people deplored the effects of sudden ambition on the mind of their chief, pitied him, wept for his untimely fate, and were ashamed they had not taken immediate revenge on his murderers. His body was exhumed, and with the head joined to it, was placed on a bier, covered with a regal purple robe, a crown of laurel on the brow, a sceptre in the right hand, and amid the solemn tolling of all the church bells it was carried in procession through the twelve districts of the town, followed, according to one historian, by 400,000 people. The viceroy, by a stroke of policy, sent his own pages in state, and ordered that funeral honours should be rendered to the "Capo del Popolo," whose body, after having lain in state several days, was finally buried with all the pomp reserved to men of the highest rank. The Duke d'Arcos, when the popular excitement had subsided, was perfidious enough to persecute numbers of the lower orders who had taken part in the revolution, thus causing the memory of Masaniello to be more than ever regretted. To this day he is held in high esteem by the liberal party of the *lazzaroni* of Naples, who regard him as the glory of their class, and the standard of popular heroes.

The most complete account of this remarkable episode in history was contained in a manuscript of the Padri Filippini dell' Oratorio in Naples. The monks consented only lately to publish this interesting document. It is entitled *Diario di Francesco Capecelatro contenente la storia delle cose avvenute nel Reame di Napoli negli anni* 1647–50, *ora par la prima volta messo a stampa, etc dal Marchese Angelo Granito*, Napoli, 1854, presso G. Nobile. (E. F.)

MASBATE, one of the Philippine Islands, in the Indian Archipelago, situated to the S. of Luzon and W. of Samar, in the middle of the Bisaya Sea. The shape of the island is triangular; it is about 70 miles in length by 20 in average breadth; and its area is computed at 1225 square miles. It consists for the most part of rocky mountains, with only a small portion of cultivated land, and is very thinly populated. The principal article of produce is rice. The island contains the harbours of Barreras and Catayugan.

MASCALI NUOVO, a town in Sicily, province of Catania, is situated at the foot of Mount Etna, on a small river about 2 miles from the sea, and 18 miles N.N.E. of Catania. The town is ill built, and, though formerly flourishing, is now in a declining condition. Fishing, however, is still actively carried on; and there is some trade in lime, lava, timber, corn, wine, and fruits. The surrounding country is fertile, and contains many thriving villages. A little to the N.W. stands the village of Mascali Vecchio. There have been found here many curious remains of antiquity, especially of the Saracenic period. Pop. about 4000.

MASCARA, a town of Algeria, province of Oran, pleasantly situated on the S. slope of the Atlas range, 45 miles S.E. of Oran. It was formerly the residence of Abd-el-Kader, and was strongly fortified and defended by a castle. It was taken and burnt by the French in 1835, and was again taken by them in 1841, since which time it has remained in their possession. It has been much improved since it came into the hands of the conquerors, and is now strongly garrisoned. Pop. (1851) 4915, of whom 3210 were natives.

MASCHERONI, Lorenzo, an Italian mathematician, was born at Bergamo in 1750. Intended for the church, he devoted his attention to the classical languages, and studied so successfully, that at the age of eighteen he was appointed professor of humanity in the university of his native city. From this situation he was promoted to the chair of Greek at Pavia. Chancing, however, in his twenty-seventh year, to take up a book on mathematics, he conceived so intense an enthusiasm for that science, that he forthwith renounced all other studies for its sake. His former success attended him in this new pursuit, and he was soon appointed professor of geometry in the college of Mariano at Bergamo. In 1795 he published at Milan his *Geometry of the Compass*, a work which secured for him the patronage of Bonaparte. Mascheroni, priest though he was, became a zealous promoter of the revolution that attended the invasion of Italy by the French. Accordingly he was elected a member of the legislative body of the Cisalpine Republic. In 1798 he was sent to Paris to study the French system of weights and measures, and to apply it to Italy. His zeal, however, in discharging this duty, was the cause of an illness which closed his career in July

1800. Mascheroni's chief work, *The Geometry of the Compass*, was translated into French by M. Carette, 8vo, Paris, 1798. (See *Fifth Dissertation*, § i.)

MASERES, Baron. (See *Fifth Dissertation*, p. 709.)

MASHAM, a market-town of England, North Riding of Yorkshire, on the Ure, 16 miles S.S.E. of Richmond. It has a parish church in the early English style, surmounted by a lofty spire, several Dissenting places of worship, a grammar school, mechanics' institute, a library, a literary and several benevolent societies. The inhabitants are chiefly employed in the manufacture of woollen stuffs and in the spinning of flax. Pop. (1851) 1139.

MASINISSA, a celebrated African prince, son of Gala, king of the Numidian tribe of the Massyli, was born about 239 B.C. Receiving his education at Carthage, and thus becoming interested in the welfare of that city, he incited his father in 213 B.C. to form a league with the Carthaginians. In the same year, accordingly, Masinissa, at the head of a troop of Numidian cavalry, sailed for Spain, and served most devotedly in the war against the Romans. But the check which the Punic fortunes received at Silpia in 206 B.C. shook his fidelity, and he resolved to pass over to the Romans on the first safe opportunity. This resolution was strengthened by the generosity which his nephew Massiva had experienced from Scipio, and probably also by the intelligence that Sophonisba, the beautiful daughter of Hasdrubal, to whom he had been betrothed, was about to be wedded to Syphax, the prince of the Numidian tribe of the Massæsyli. Meanwhile an event had occurred in Africa that accelerated the defection of Masinissa. The crown of his native country, which, after the death of his father Gala, had passed in rapid succession to his uncle Œsalces, and his cousin Capusa, was seized at this time in the name of an infant brother of the latter by Mezetulus. On hearing of this usurpation, Masinissa crossed to Africa, rallied around his standard the old soldiers of his father, defeated Mezetulus in a pitched battle, and forced him to flee, along with his royal ward, into the dominions of Syphax. No sooner, however, was Masinissa seated on his ancestral throne, than he recalled the two fugitives, and by his favours disarmed their hostility. But a more formidable foe immediately appeared in the person of Syphax. Instigated and backed by the Carthaginians, that prince invaded the Massylian territories, and annihilated in quick succession those armies which had been hastily mustered to oppose him. Thus stripped of his sovereignty, and driven from his kingdom, Masinissa was obliged to skulk with a few followers near the sea-shore, until the landing of Scipio in 204 B.C. gave him the opportunity which he had for some time wished, of identifying his cause with that of the Romans. He joined the invaders with a part of his shattered forces, and by his active fidelity, and his knowledge of the habits of the enemy, contributed in no small degree to the two victories gained over Hasdrubal and Syphax. On the capture of Cirta, the metropolis of the Massæsyli, Masinissa obtained possession of Sophonisba, the wife of Syphax, and, with her own consent, married her. But Scipio severely censured his marriage with so determined a foe of the Romans; and Sophonisba, by the advice of her newly-espoused husband, poisoned herself to escape the ignominy of falling into the power of her enemies. The grief of Masinissa for this untoward event was allayed by his reinstalment into the sovereignty of the Massylians. From the quiet possession of his power, however, he was soon summoned by the arrival of Hannibal in Africa. In the decisive conflict of Zama which followed (202 B.C.), he made a brilliant charge at the head of his Numidian horse, drove the cavalry of Hannibal from the field, and was thus the first to turn the tide of battle against the Carthaginians. For this important service he was rewarded in the following year with the greater part of the kingdom of Syphax. Firmly fixed in his possessions, with the title of King of Numidia, Masinissa now devoted his attention to the organization of his government and the improvement of his people. Yet at times his ambitious spirit, and his reliance upon the powerful support of Rome, incited him to provoke by aggressions the humbled Carthaginians. In all these disputes the Romans acted as mediators, and uniformly favoured the Numidian king. At length in 150 B.C. the Carthaginians, indignant at the intrigues which Masinissa had been carrying on against the welfare of their city, commenced acts of hostility. Masinissa accordingly marched into their territories, and though deserted by several of his chiefs, he adroitly circumvented the enemy, and forced them to capitulate. He died in 148 B.C., at the age of ninety, while Roman ambassadors were on the way to his palace to demand reinforcements for the third Punic war. In accordance with his dying request, his kingdom was divided between his three sons, Micipsa, Gulussa, and Mastanabal.

Masinissa displayed all the qualities that render a prince the favourite of semi-barbarian subjects. Not destitute of skill in strategy, he also possessed a dauntless valour in action, and an unshaken magnanimity under reverses. He shared the hardships and fare of the meanest soldier; and till within a short time before his death, he underwent with surprising agility all the warlike exercises of youth. His attempts to civilize his people were highly praiseworthy.

MASKELYNE, Nevil, a most industrious and accurate astronomer, born in London on the 6th of October 1732, was the son of Mr Edmund Maskelyne, a gentleman of respectable family in Wiltshire.

At the age of nine he was sent to Westminster School, and continued to apply with diligence to the usual pursuits of that place, until the occurrence of the great solar eclipse of 1748, which made a strong impression on his mind, and was the immediate cause of his directing his attention to astronomy, and beginning with great ardour the study of the mathematics as subservient to that of astronomy. It is remarkable, that the same eclipse is said to have made an astronomer of Lalande, who was only three months older than Maskelyne. He soon afterwards entered as a member of Catherine Hall, Cambridge, but in a short time removed to Trinity. He took the degree of Bachelor of Arts with great credit in 1754, and proceeded regularly afterwards through the succeeding stages of academical rank in divinity. He was ordained in 1755 to a curacy at Barnet, and the next year he obtained a fellowship at Trinity. In 1758 he was elected a fellow of the Royal Society; having previously become intimate with Dr Bradley, and determined to make astronomy the principal pursuit of his life, feeling its perfect compatibility with an enlightened devotion to the duties of his own profession.

In 1761 he was engaged by the Royal Society to undertake a voyage to St Helena in order to observe the transit of Venus. He remained ten months in that island, but the weather prevented his observing the transit to advantage; and the faulty attachment of the plumb-line of his quadrant, which was of the construction then usually employed, rendered his observations on the stars less conclusive with respect to annual parallax than he had expected. His voyage was, however, of great use to navigation, by promoting the introduction of lunar observations for ascertaining the longitude; and he taught the officers of the ship which conveyed him the proper use of the instruments, as well as the mode of making the computations.

He performed a second voyage in 1763 to the island of Barbadoes in order to determine the rates of Harrison's watches, and also to make experiments with Irvine's marine chair on board of the "Princess Louisa," Admiral Tyrrel; acting at the same time as chaplain to the ship. The chair he found of very little use for observing the eclipses of Jupiter's satellites; and the maker of the chronometers was not satisfied with his report of their performance, fancying that he was too partial to the exclusive employment of lunar observations for determining the longitude. The liberality of the British government, however, bestowed on Harrison the whole reward that he claimed; and Maskelyne having been appointed to the situation of astronomer-royal, and having thus become a member of the Board of Longitude, was extremely active in obtaining a few thousand pounds for the family of Professor Mayer, who had computed lunar tables, and a compliment of L.300 for Euler, whose theorems had been employed in the investigation.

The merits of Mayer's tables having been fully established, the Board of Longitude was induced to promote their application to practical purposes by the annual publication of the *Nautical Almanac*, which was arranged and conducted entirely under Maskelyne's direction for the remainder of his life. He was also actively employed, without any other motive than the love of science and of his country, in almost every decision which was required of the Board of Longitude; and he had to give his opinion of the merits of an infinite number of fruitless projects which were continually submitted to his judgment. He must of course have made many enemies amongst the weak and illiberal; but the universal impartiality and the general accuracy of his determinations were acknowledged by all candid persons; and it must be admitted, that the longitudinarys peculators of Great Britain in those days submitted to discouraging remarks from persons in authority, with wonderful fortitude and with great personal civility.

During the forty-seven years that he held the situation of astronomer-royal, he acquired the respect of all Europe by the diligence and accuracy of his observations, which he never neglected to conduct in person whenever it was in his power, and he required only one assistant. The French had a handsome building to amuse the public by its exterior magnificence; but the establishment of the observers was never arranged in so methodical a manner as that of the English national observatory, and the fruits of their labours were never systematically made public, the attempt which was once made by Lemonnier in his *Histoire Céleste* having been interrupted and discontinued. Dr Maskelyne, on the other hand, obtained leave from the British government to have his observations printed at the public expense under the direction of the Royal Society, who are the legal visitors of the observatory, appointed by the royal sign manual. The early observations of Flamsteed and of Bradley were considered as private property. Flamsteed published his own, and Bradley's were very liberally bought of his family, and afterwards printed by the university of Oxford, who are still as liberal in bestowing them where they are likely to be employed for the benefit of science. Flamsteed was the astronomer-royal from 1690 to 1720, then Halley to 1750, Bradley to 1762, and Bliss to 1765, when Maskelyne was appointed. He took his doctor's degree in the year 1777.

He made several improvements in the arrangement and employment of the instruments, particularly by enlarging the slits through which the light was admitted; by making the eye-glass of his transit telescope moveable to the place of each of the wires of the micrometer; and, above all, by marking the time to tenths of a second, which had never been attempted before, but which he found it practicable to effect with surprising accuracy, as the comparison of the observations at the different wires sufficiently demonstrated.

The object of his expedition to Schchallien is well known. Bouguer had made an unsuccessful attempt to measure the attraction of a mountain in South America, and had been obliged to conclude that the mountain was hollow, in consequence of the eruption of a volcano, the attraction being too little sensible. Dr Maskelyne's results, on the other hand, as computed by Dr Hutton, made the mountain more dense than could well have been expected; but those who are acquainted with the difficulty of executing astronomical measurements without an error of a single second of space, will be ready to allow that the deviation of 5″ or 6″, attributed to the effect of the mountain, is liable to a much greater proportional uncertainty than the results obtained by Mr Cavendish with the apparatus invented by Mr Michell. (See CAVENDISH.) The geodesical operations which were soon afterwards performed, with his concurrence and assistance, for determining the relative situations of Greenwich and Paris, were equally creditable to the English artists who constructed the instruments, and to the astronomers and geographers who made the observations with them; and, even by the confession of their rivals, they excelled everything that had ever been effected in former measurements of the same kind.

As no man had done more for practical astronomy than Dr Maskelyne, so there was none whose merits were more justly appreciated. He made every astronomer his friend, as well by his personal kindness as by his professional labours; and he obtained the rare distinction of being made one of the eight foreign associates of the French Academy of Sciences. His example and encouragement contributed to the establishment of several private observatories, which must always be, if not immediately, at least remotely, beneficial to astronomy, as tending to promote the improvement of instruments and of the methods of employing them.

He was modest, and somewhat timid in receiving the visits of strangers; but his usual conversation was cheerful, and often playful, with a fondness for point and for classical allusion. He inherited a good paternal property, and he obtained considerable preferment from his college; he also married, somewhat late in life, the sister and coheiress of Lady Booth of Northamptonshire. His sister was the wife of Robert Lord Clive and the mother of the Earl of Powis. He died on the 9th of February 1811, in his seventy-ninth year, leaving a widow and an only daughter.

Dr Maskelyne's first communication to the Royal Society is, A Proposal for discovering the Annual Parallax of Sirius. (*Phil. Trans.* li., 1760, p. 889.) It is founded on Lacaille's observations made at the Cape of Good Hope, which appeared to indicate a maximum amounting to 8″. 2. A Theorem for Spherical Aberration (lii., 1761, p. 17), dated from the "Prince Henry," St Helen's Roads, the calculation being adapted to the object-glasses of achromatic telescopes. 3. The next article (p. 21) is a letter from Lacaille recommending that he should make observations at St Helena on the lunar parallax, and remain some time in the island for that purpose, and promising, on his own part, to make corresponding observations. It is followed by a letter from Maskelyne proposing some additional joint observations. 4. Observation of the Transit of 1761 (p. 196). The sun was lower than had been expected, and the instant of contact uncertain, from a tremulous motion in the apparent discs. 5. Observations on a Clock of Shelton (1762, p. 434), giving the proportion of ·99754 to 1 for the comparative force of gravity at Greenwich and at St Helena. 6. A Letter on the Mode of observing and computing Lunar Distances (p. 558), dated from St Helena; the first demonstration of the practicability and utility of the method. He found the error of observation not to exceed half a degree of longitude, an error which was very strangely suffered to remain as a fair allowance for the uncertainty of observation in the acts for encouraging the perfection of the lunar tables, subsequently repealed. 7. On the Tides at St Helena (p. 586); observations made in a harbour for about two months. 8. Note to Lalande (p. 607) on Lunar Distances and Occultations. 9. Rules for correcting Lunar Distances (*Phil. Trans.*, 1764, p. 263); a demonstration of the rules before published in the *Transactions* and in the *British Mariner's Guide*. 10. Remarks on the Equation of Time (p. 336); correcting a mistake of Lacaille and an inadvertence of Lalande, and giving a formula, which, though not geometrically perfect, is abundantly accurate for all practical purposes. 11. Astronomical Observations made at St Helena (p. 348). The observations for determining the lunar parallax were too few to afford a satisfactory result. The author suggests that the figure of the earth might be ascertained by repeated and comparative observations of the apparent distance of the moon from neighbouring stars. 12. Observations made at Barbadoes (p. 189), especially on Jupiter's satellites. 13. Introduction to two Papers of Mr Smeaton (lviii., 1768, p. 154); the one on the menstrual parallax, the other on observing stars out of the meridian. 14. Introduction to the Observations of Mason and Dixon (p. 270). 15. Conclusion respecting the Length of a Degree (p. 323, 325). Mr Charles Mason had been sent with Mr Dixon to observe the transit of 1761 at Bencoolen, but their voyage was interrupted by accidental circumstances, and they made their observations at the Cape of Good Hope with tolerable success. They then proceeded to join Maskelyne at St Helena, and to assist in his operations there. They were afterwards engaged by Lord Baltimore and Mr Penn to determine the boundaries between Maryland and Pennsylvania; and having completed their survey, they suggested to the council of the Royal Society the eligibility of measuring a degree in the country bordering on the Delaware and the Chesapeake. Their proposals were readily accepted, and the results of their measurement are here recorded. Dr Maskelyne afterwards employed Mason in his operations on Schehallien, in computing Bradley's observations, and in improving Mayer's tables by a comparison with them; but he was so fearful of admitting any empirical corrections not founded on the most general principles, that he would not allow some of the equations discovered by Mason to be introduced into the computation of the *Nautical Almanac* until M. de Laplace had proved their dependence on the theory of gravity. Lalande tells us that Mason was dissatisfied because he did not receive a public reward for the success of his labours; but he was, in fact, little more than the agent of Maskelyne and of the Board of Longitude; and he was fairly repaid for the time and labour which his computations had required. Delambre says that he died in Pennsylvania in 1787. Dixon is said to have been born in a coal mine, and to have died at Durham in 1777. 15. Postscript respecting French and English Measures (p. 325). The result of this comparison agrees remarkably well with the later measurement of Pictet, Prony, and Captain Kater. 16. Observation of the Transit of 1769, made at the Royal Observatory (p. 355). 17. Eclipses and Occultations, 1769 (p. 399), chiefly for the longitude of Glasgow. 18. On the Use of Dollond's Micrometer, 1771 (p. 536). On the application of the divided object-glass micrometer to determining differences of right ascension and of declination, especially in the case of transits; a part of the instructions sent with the observers to the South Seas. 19. On the Adjustment of Hadley's Quadrant, 1772 (p. 99), especially for the back observation, and to insure the parallelism of the glasses. 20. Deluc's Rule for Measuring Heights, 1774 (p. 158), adapted to English measures, and rendered somewhat more convenient. 21. Observations at Greenwich and in America compared (p. 184, 190). 22. Proposal for Measuring the Attraction of a Hill, 1775 (p. 495); read in 1772. 23. Observations made on Schehallien (p. 500); a paper which obtained its author the honour of a Copleian medal. Mason had been sent to examine the hills of Scotland, and had recommended Schehallien; the funds were supplied by the remainder of the royal grant for observing the transit of Venus. Mr Reuben Burrow and Mr Menzies were principally employed in assisting the astronomer-royal in his observations and surveys; and Dr Hutton afterwards made the necessary computations for determining the attraction of the mountain. 24. Description of a Prismatic Micrometer, 1777 (p. 799), consisting of one or more prisms sliding in the axis of the telescope, and resembling in its operation that of Rochon, which has in great measure superseded it. 25. On the Longitude of Cork, 1779 (p. 179); observations for correcting the computed times of the eclipses of Jupiter's satellites. 26. On the Comet expected in 1789 (*Phil. Trans.*, 1786, p. 426); supposing those of 1532 and 1661 to be the same. (See MECHAIN.) 27. On the Latitude and Longitude of Greenwich, 1787 (p. 151); with Cassini's Memoir on its uncertainty, which he states as amounting to 11″ in longitude, and 15″ in latitude. Dr Maskelyne, however, shows that it is confined within much narrower limits, though he approves of the object of the memoir in promoting a survey. 28. On a Difficulty in the Theory of Vision, 1789 (p. 256). This paper sufficiently proves that Euler was mistaken in thinking the eye achromatic; and that any appearance of colour which it could produce, according to the common laws of refraction, would be imperceptible in ordinary circumstances. But that there are circumstances under which such appearances may be observed, was afterwards shown by Dr Young and Dr Wollaston. 29. Account of an Appearance of Light on the Dark Part of the Moon, 1793 (p. 429); seen by Mr Wilkins and by a servant of Sir George Booth, and supposed to have arisen from a volcano. 30. Observations of the Comet of 1793 (*Phil. Trans.*, 1794, p. 55); discovered by the Rev. E. Gregory of Langar, in Nottinghamshire. 31. The earliest of Maskelyne's separate publications was the *British Mariner's Guide*, London, 763, 4to,—a small volume, which has become scarce, having been superseded by later works. 32. The *Nautical Almanac* and *Astronomical Ephemeris* for 1767 appeared in 1766; and the publication was regularly continued upon the same plan for some time, by the computers and comparers whom Dr Maskelyne had trained by his instruction and example. His successor in the observatory, though admirably qualified to equal, and perhaps to excel him in the practical department, had it not in his power to devote so much of his attention to the publication as Dr Maskelyne's paternal affection for a child of his own had induced him to bestow on it; and the Board of Longitude was very liberally furnished by government with the means of obtaining some further assistance to supply his place. 33. Tables requisite to be used with the *Nautical Almanac*, London, 1766, 1783, 1802, 8vo,—since partly superseded by Professor Lax's new edition. 34. The volume of Selections, from the additions that have been occasionally made to the *Nautical Almanac*, London, 1812, 8vo, contains several papers of Dr Maskelyne; for example, Instructions relating to the Transit of Venus in 1769, N. A. 1769; Elements of Lunar Tables, and Remarks on Hadley's Quadrant, N. A., 1774; Advertisement of the Comet expected in 1788, N. A., 1791; and on the Disappearance of Saturn's Ring in 1780, N. A., 1791. 35. The Astronomical Observations made at Greenwich, from 1765 to 1811, were published annually in folio, making 3 vols., and part of a fourth, London, 1774. They are allowed to constitute the most perfect body of astronomy in detail that was ever presented to the public. The first volume contains a variety of useful tables, accompanying the observations for 1772, and principally serving for the correction of the places of the stars, and for facilitating the solution of other astronomical problems. Many of them have been reprinted in Vince's *Astronomy*, but in some cases without the necessary explanations. (T. Y.)

(Kelly in Rees's *Cyclopædia*, art. "Maskelyne;" Chalmers, *Biographical Dictionary*, xxi., 8vo, London, 1815; Delambre, *Mém. de l'Inst. des Sc.*, 1811, H. lix.; and *Biographie Universelle*, xxvii., 8vo, Paris, 1820.)

MASON, WILLIAM, an English poet, born in the year 1725, was the son of a clergyman who held the living of Hull. He was educated at Cambridge, and was admitted a fellow of Pembroke College in 1747. He became rector of Aston in Yorkshire, and chaplain to his Majesty; and was subsequently made precentor and canon residentiary of the cathedral of York. His monody to the memory of Pope; and *Isis*, an elegy; added to his fame, which was still further increased by his dramatic poems of *Elfrida* in 1752, and *Caractacus* in 1759, written after the manner of the ancients. He published a small collection of odes in 1756, intended as an imitation of his friend Gray, which afforded Colman and Lloyd effective subjects for clever parodies. In 1763 he produced some elegies marked by simplicity of language and noble sentiment. In point of morality he may justly be considered as the purest of poets, and one of the warmest friends of civil liberty. The first book of his *English Garden* made its appearance in 1772, being a dull didactic poem in blank verse, of which the fourth and last book was printed in the year 1781. In 1775 he published the poems of Gray, to which he prefixed memoirs of his life and writings; and in 1783 he produced an elegant poetical translation of Dufresnoy's Latin poem on the art of painting; besides *An Historical and Critical Essay on English Church Music*. An additional volume of his poems was given to the world in 1797, consisting of miscellaneous pieces, the revised productions of his youth, and the effusions of his old age. He died in April 1797, at the age of seventy-two. A tablet has been placed to his memory in the Poets' Corner in Westminster Abbey.

MASONRY. See STONE MASONRY.

MASONRY, *Free*, denotes the rule or system of mysteries and secrets peculiar to the society of free and accepted masons.

One of the first objects of man, in a rude state of being, is to screen himself and his family from the heat of the tropical sun, from the inclemency of the polar regions, or from the sudden changes of more temperate climates. If he has arrived at such a degree of improvement as to live under the dominion of a superior, and under the influence of religious belief, the palace of his king and the temple of his gods will be reared in the most magnificent style which his skill can devise and his industry accomplish.

Architecture is accordingly entitled to a very high position amongst the other arts. It is itself the parent of many separate professions, and requires a combination of talent and an extent of knowledge for which few other professions have, for the most part, any occasion. There is some foundation in the very nature of architecture for those extraordinary privileges to which masons have always laid claim, and which they have almost always possessed; and there appears also to be some foundation for that ancient and respectable order of free masons whose history we are now to investigate, without, at the same time, revealing those ceremonial observances which are only known to the brethren of the order.

Free masonry is an ancient and respectable institution, embracing individuals of every nation, religion, and condition in life. In order to confirm this institution, and attain the ends for which it was originally formed, every candidate comes under a solemn engagement never to divulge the mysteries of the order, nor communicate to the uninitiated the secrets with which he may be intrusted, and the proceedings and plans with which the fraternity may be engaged. After the candidate has undergone the necessary ceremonies, and received the usual instructions, appropriate words and significant signs are imparted to him, that he may be enabled to distinguish his brethren of the order from the uninitiated vulgar, and convince others that he is entitled to the privileges of a brother, should he be visited by distress or by want in a distant land. If the newly-admitted member be found qualified for a higher degree, he is promoted, after due intervals of probation, till he has received that masonic knowledge which enables him to hold the highest offices of trust to which the fraternity can raise its members. At regular and appointed seasons convivial meetings of the fraternity are held, in lodges constructed for this purpose, when all distinctions of rank and differences in religion and politics are forgotten. Every one strives to give happiness to his brother; and all seem to recollect, for once, that they are sprung from the same origin, possessed of the same nature, and destined for the same end. Respecting the origin and tendency of this institution, opinions differ. Whilst a certain class of men have represented it as coeval with the world, others have maintained that it was the invention of English Jesuits, to promote the views of that intriguing and dangerous association. Some have laboured to prove that free masonry arose during the crusades; that it was a secondary order of chivalry; that its forms originated from that warlike institution, and were adapted to the peaceful, orderly habits of scientific men. Mr Clinch (*Anthologia Hibernica*, 1794) has attempted, with considerable ingenuity and learning, to deduce its origin from the institutions of Pythagoras. M. Barruel (*Memoirs of Jacobinism*, vol. ii.) supposes it to be a continuation of the society of knights templars; whilst others have imputed its origin to secret associations, averse to the interests of true government, and pursuing the chimerical project of levelling the distinctions of society, and freeing the human mind from the obligations of religion and morality. But without adopting any of these untenable opinions, we may at all events establish its claim to a comparatively early origin.

The desire for pomp and ceremony displayed at an early period by the Roman Catholic priests in the exercise of their religion, introduced a corresponding desire for splendid monasteries and magnificent cathedrals. In order to encourage the profession of architecture, the pontiffs of Rome, and the other potentates of Europe, conferred on the fraternity of free masons the most important privileges, and allowed them to be governed by laws, customs, and ceremonies peculiar to themselves. The association was composed of men of all nations, of Italian, Greek, French, German, and Flemish artists, who were denominated free masons, and who, travelling from one country to another, erected those elegant churches and cathedrals which men still admire. The government of this association was remarkably regular. Its members lived in a camp of huts, reared beside the building in which they were employed. A surveyor or master presided over and directed the whole. Every tenth man was called a warden, and overlooked those who were under his charge; and such artificers as were not members of this fraternity were prohibited from engaging in those buildings which free masons alone had a title to rear (Wren's *Parentalia*, p. 306, 307. Henry's *Hist. of Great Brit.*, vol. viii., p. 273). In 1140 A.D., wherever the Roman Catholic religion was taught, the meetings of free masons were sanctioned and patronized. That free masonry was first introduced into Scotland by those architects who built the abbey of Kilwinning, is manifest, not only from authentic documents, by means of which the existence of the Kilwinning lodge has been traced back as far as the end of the fifteenth century, but also by other weighty collateral arguments. (*Statis. Ac. of Scot.*, vol. xi.) When we consider that the association of free masons monopolized the building of religious structures in Christendom, we are warranted to conclude that those numerous and elegant ruins which still adorn various parts of Scotland were erected by foreign masons, who introduced into this island the customs of their order.

It was probably about this time, also, that free masonry was introduced into England; but whether the English received it from the Scottish masons at Kilwinning, or from other brethren who had arrived from the continent, there are now no means of determining. The masonic fraternity in England, however, maintain that St Alban, the protomartyr, who flourished about the end of the third century, was the first who brought masonry to Britain; that the brethren received a charter from King Athelstane, and that his brother Edwin summoned to meet at York all the lodges which formed the first grand lodge of England in A.D. 926. But these assertions are inconsistent with several historical events which rest upon indubitable evidence. (Plot's *Nat. Hist. of Staffordshire*, chap. viii.)

After the establishment of the Kilwinning and the York lodges, the principles of free masonry were rapidly diffused throughout both kingdoms, and several lodges were erected in different parts of the island. As all these derived their existence and authority from the two mother lodges, they were likewise under their jurisdiction and control; and when any differences arose connected with the art of building, they were referred to the general meetings of the fraternity held at Kilwinning and at York. In this manner did free masonry flourish for a while in Britain after it was completely abolished in every other part of the world. But even here it was doomed to suffer a long and serious decline, and to experience successive alternations of advancement and decay. And although, during several centuries after the importation of free masonry into Britain, the brethren of the order held their public assemblies, and were sometimes prohibited from meeting by the interference of the legislature, it can scarcely be said to have attracted general attention till the beginning of the seventeenth century. There being now no scarcity of architects, the very reason which prompted the church to protect the fraternity ceased to exist; they therefore withdrew from them that patronage which they had spontaneously proffered, and denied them even the liberty of holding their secret assemblies. But these were not the only causes which produced such a striking change in the conduct of the church towards the masonic order. As we have already stated, the spirit of free masonry was hostile to the principles of the church of Rome. The intention of the one was to enlighten the mind; the object and policy of the other were to retain it in ignorance. When free masonry flourished, the power of the church must have decayed. The jealousy of the latter was therefore aroused; and, as the civil power in England and Scotland was almost always in the hands of ecclesiastics, the church and the state were combined against the principles and the practice of free masonry. But besides the causes here specified, the domestic and bloody wars which convulsed the two kingdoms from the thirteenth to the seventeenth century conspired, in a great degree, to produce that decline of the fraternity for which we have been attempting to account. Yet notwithstanding these unfavourable circumstances, free masonry seems to have flourished, and attracted the attention of the public in the reign of Henry VI., who, when a minor, ascended the throne of England in 1422. In the third year of his reign, indeed, the parliament passed a severe act against the fraternity, at the instigation of Henry Beaufort, bishop of Winchester, who was then intrusted with the education of the young king. They enacted that the masons should no longer hold their chapters and annual assemblies; that those who summoned such chapters and assemblies should be considered as felons; and that those who resorted to them should be subjected to fine and imprisonment (3 Henry VI., cap. 2, A.D. 1425). But it would appear that this act was never put in execution; for, in the year 1429, about five years after it was framed, a most respectable lodge was held at Canterbury under the patronage of the archbishop himself. When King Henry assumed the government, he not only permitted the order to hold their meetings without molestation, but even honoured the lodges by his presence as a brother. Before he was initiated, however, into the mysteries of the order, he seems to have examined, with scrupulous care, the nature of the institution, and to have perused the charges and regulations of the fraternity, which had been collected from their ancient records.

Henry VII. became grand master of the order, and was succeeded in this office by the celebrated Cardinal Wolsey. In the reign of Queen Elizabeth an armed force was sent to break up the grand lodge at York, but some of the chiefs being induced to join the order, a report was made to the Queen, which led to the liberation of the masons from all future molestation. Several of the kings of England were subsequently grand masters of the order,—though during the reign of James II. it was much neglected; but on the accession of William III. it was revived under his majesty's auspices, who confirmed the choice of the brethren when Sir Christopher Wren was made grand master. It was not, however, until 1717 that the first regular grand lodge was formed in London, with power to grant charters for the holding of other lodges. This grand lodge having subsequently granted charters in the district which the grand lodge of York claimed as its own, all friendly communication ceased between them. Several attempts were made to heal the differences, and bring about a union of the two lodges, but they all failed until the year 1813, when H R. H. the Duke of Kent being grand master of the York or Athol masons, and H. R. H. the Duke of Sussex grand master of the London masons, that desirable end was effected. The Duke of Sussex became the grand master of the united body, which he continued to hold until his death in 1843, since which time the Earl of Zetland has presided over the order. The grand lodge of England has at this time upwards of 1000 lodges under its jurisdiction. It is possessed of very great wealth; and in addition to dispensing about L.2000 a year for philanthropic purposes at a monthly board, has given, up to the close of last year, upwards of L.21,000 to the four masonic charities, viz.—the Girls' School, established 1788; the Boys' School, established 1798; the Benevolent Fund for Aged Masons, established in 1842; and the Widows' Fund, established in 1850.

Whilst free masonry flourished in England under the auspices of Henry VI., it was making progress at the same time in the sister kingdom of Scotland. By the authority of James I. of Scotland, every grand master who was chosen by the brethren, either from the nobility or clergy, and approved of by the crown, was entitled to an annual revenue of four pounds Scots from each master mason, and likewise to a fee at the initiation of every new member. He was empowered to adjust any differences which might arise amongst the brethren, and to regulate those affairs connected with the fraternity which it was improper to bring under the cognisance of the courts of law. The grand master also appointed deputies or wardens, who resided in the chief towns of Scotland, and managed the concerns of the order when it was inconvenient to appeal to the grand master himself. In the reign of James II. of Scotland, the office of grand master was granted by the crown to William St Clair, earl of Orkney and Caithness, baron of Roslin, and founder of the chapel of Roslin. On account of the attention which this noblemen paid to the interests of the order, and the rapid propagation of the royal art under his administration, King James II. made the office of grand master hereditary to his heirs and successors in the barony of Roslin; in which family it continued till the institution of the grand lodge of Scotland. The barons of Roslin, in the capacity of hereditary grand masters, held their principal annual meetings at Kilwinning, the birthplace of Scottish masonry, whilst the lodge of that village granted constitutions and charters of erection to those brethren of the order who were anxious that regular lodges should be instituted in different parts of the kingdom. During the reigns of the succeeding Scottish monarchs, free masonry still flourished, though very little information can be procured respecting the state of the fraternity. In the records of the privy seal, however, there exists a letter, dated at Holyroodhouse, the 25th September 1590, and granted by King James VI. "to Patrick Copland of Udaught, for using and exercising the office of wardanrie over the art and craft of masonrie, over all the boundis of Aberdeen, Banff, and Kincardine, to had warden and justice courts within the said boundis, and there to minister justice." This letter proves beyond dispute that the kings of Scotland nominated the office-bearers of the order; that these provincial masters, or wardens as they were then called, administered justice in every dispute which concerned the "art and craft of masonrie;" that lodges had been established in all parts of Scotland, even in those remote, and, at that time uncivilized, counties of Aberdeen, Banff, and Kincardine.

When James VI. ascended the throne of England he seems to have neglected his right of nominating the office-bearers of the craft. In Hay's manuscript in the Advocates' Library, there are two charters granted by the Scottish masons, appointing the St Clairs of Roslin their hereditary grand masters. The former of these is without a date, but is signed by several masons who appoint William St Clair of Roslin, his heirs and successors, their "patrons and judges." The latter is in some measure a ratification of the former, and dated 1630, in which they appoint Sir William St Clair of Roslin, his heirs and successors, to be their "patrons, protectors, and overseers, in all time coming." In the year 1736, on the resignation of William St Clair as grand master, thirty-two lodges met and elected him grand master mason of all Scotland; and thus was instituted the grand lodge of Scotland.

The most remarkable event of recent times in free masonry has been the permission given by the grand master to the *Free Masons' Magazine* to publish the reports of proceedings in grand and private lodges.

MASORA, a term in the Jewish theology, signifying a work on the Bible, executed by several learned rabbis, in order to secure it from any alterations. (See PHILOLOGY, § *Hebrew Language*.)

MASQUERADE (Ital. *Mascherata*, Fr. *Mascarade*), a species of amusement, common to most civilized countries, in which persons of both sexes mask or disguise themselves, and engage in dancing, festivities, and miscellaneous conversation. Masquerades are said to have been invented by Granacci, an Italian, in the beginning of the sixteenth century. At all events they were fashionable in Italy as early as 1512, when they were introduced into England in the reign of Henry VIII., as old Hall informs us in his *Chronicle* (4to, London, 1809, p. 526). He says, "On the daie of the Epiphanie at night (1512-13,) the king (Henry VIII.) with a.xi. other were disguised, after the maner of Italie, called a maske, *a thyng not seen afore in Englande*, thei were appareled in garmentes long and brode, wrought all with gold, with visers and cappes of gold & after the banket doen, these maskers came in, with sixe gentlemen disguised in silk" (which some take for the modern *domino*) "bearyng staffe torches, and desired the ladies to daunce, some were content, and some that knewe the fashion of it refused, because it was not a thyng commonly seen. And after thei daunced and commoned together, as the fashion of the maske is, thei tooke their leaue and departed, and so did the quene, and all the ladies."

MASS, in the church of Rome, means the prayers and ceremonies used at the celebration of the Eucharist; or, in other words, in consecrating the bread and wine into the body and blood of Christ, as it is said, and offering them so transubstantiated as an expiatory sacrifice for the living and the dead. As the mass is believed by Roman Catholics to be a representation of the passion of our blessed Saviour, so every action of the priest, and every particular part of the service, is supposed to allude to the particular circumstances of his passion and death. The ceremonies and usages of the mass were first settled by Gregory the Great in the sixth century. The service consists of three parts: the offering of the elements, their consecration, and their sumption or participation by those who communicate. The language used in the mass is Latin, first employed in A.D. 394. (For the various views respecting the Eucharist and the sacrifice of the mass, see the article SUPPER.)

Nicod, after Baronius, observes that the word *mass* comes from the Hebrew *missach*, *oblatum*, or from the Latin *missa*, *missorum*, because in former times the catechumens and excommunicated persons were sent out of the church when the deacons said *Ite, missa est*, after sermon and reading of the epistle and gospel; they not being allowed to assist at the consecration. And hence the distinction of *missa catechumenorum* and *missa fidelium*.

The general division of masses consists of high and low. The first is that which is sung by the choristers, and celebrated with the assistance of a deacon and sub-deacon; low masses are those in which the prayers are merely rehearsed without singing.

There are many different or occasional masses in the Latin church, some of which have nothing peculiar but the name: such as, the masses of the saints; that of St Mary of the snow, celebrated on the 5th of August; that of St Margaret, patroness of lying-in women; that of the feast of St John the Baptist, at which are said three masses; that of the innocents, at which the *Gloria in excelsis* and the *Alleluia* are omitted, and, it being a day of mourning, the altar is of a violet colour. As to ordinary masses, some are said for the dead. At these masses the altar is put in mourning, and the only decorations are a cross in the middle of six yellow wax-lights; the dress of the celebrant and the mass-book are black; many parts of the office are omitted, and the people are dismissed without the benediction. If the mass be said for a person distinguished by his rank or virtues, it is followed with a funeral oration. They erect a *chapelle ardente*, that is, a representation of the deceased with branches and tapers of yellow wax, either in the middle of the church or near the tomb of the deceased, where the priest pronounces a solemn absolution of the deceased. There are likewise private masses said for the recovery of stolen or strayed goods or cattle, for health, for travellers, &c., which go under the name of *votive masses*. There is still a further distinction of masses, which are denominated from the countries in which they were used. Thus the Gothic mass, or *Missa Mosarabum*, is that which was used amongst the Goths when they were masters of Spain, and is still kept up at Toledo and Salamanca; the Ambrosian mass is that composed by St Ambrose, and used only at Milan, of which city he was bishop; the Gallic mass is that used by the ancient Gauls; and the Roman mass is the one used by almost all the churches in the communion of the Roman Catholic Church. The mass of the Presanctified (*Missa Præsanctificatorum*) is a mass peculiar to the Greek church, in which there is no consecration of the elements; but, after singing some hymns, they receive the bread and wine which was before consecrated. This mass is performed during the whole of Lent, excepting on Saturdays, Sundays, and the Annunciation.

MASSA DI CARRARA, or MASSA DUCALE, a town of Italy, formerly capital of the duchy of that name, is pleasantly situated near the left bank of the Frigido, about 2 miles from its mouth, and 58 S.W. of Modena. The town has several fine streets and squares, one of the latter of which is planted with orange trees; and its chief buildings are a cathedral and a palace. The manufacture of silk is carried on here, as well as a considerable trade in the fine marble which is got in the neighbourhood, and which is called Carrara marble. The duchy was, in the middle ages, for some time under the power of the Genoese; and afterwards, for several centuries, belonged to the house of Malaspina till it passed by marriage to the Genoese family of Cibo, who were at first Counts of Florentillo, but were raised by the Emperor Maximilian II. to the rank of Princes of Massa and Margraves of Carrara, and by Leopold in 1664 to that of Dukes of Massa and Princes of Carrara. In 1741 Maria Theresia Francisca, the heiress of Carrara, married Hercules Rainald, the heir of Modena; and their daughter Beatrice, Duchess of Este, married Ferdinand, Archduke of Austria, and inherited Massa and Carrara. Though dispossessed by the French in 1796, this princess was restored to her rights by the Congress of Vienna; and, on her death in 1829, the duchy was united to Modena, of which it now forms the province of Massa Carrara. Pop. of the province (1850) 56,867; of the town, 8000.

MASSACHUSETTS, one of the (eastern) United States of North America, lies between 41. 30. and 43. 52. N. Lat., and 69. 30. and 77. 30. W. Long. It is bounded N. by New Hampshire and Vermont, S. by Connecticut and Rhode Island, E. by the Atlantic Ocean, and W. by New York. It is about 190 miles in length, with an average breadth of nearly 90 miles, and an area of about 7300 square miles. Among the six New England states, Massachusetts holds a central position, and is the most important of them in several points of view. It presents a surface pleasantly undulated with hills and valleys, and is naturally divided into three distinct zones. The first, stretching along the seashore, and extending 20 miles into the interior, is a belt of marine alluvium, little elevated above the ocean, and naturally fertile only at intervals. This plain is succeeded by a fine hilly tract, which crosses the state from N. to S., and from which rivers are poured in every direction. The second or middle zone includes part of the beautiful valley of Connecticut, and is followed by the mountainous but highly fertile county of Berkshire, which comprises the

Massachusetts.

whole western part of the state. The soil of Massachusetts is exceedingly various, comprising every description, from the most sterile to the most productive. In the eastern and south-eastern parts it is in general light and sandy, interspersed, however, with numerous fertile tracts. Towards the sea-coast on the N. it is of better quality, though not distinguished for fertility. By careful cultivation, however, both this and other parts of the state have been rendered highly productive. The middle and western regions have for the most part a strong, rich soil, excellent for grazing, and suited to most other agricultural purposes. Viewed at a glance, the surface of this state swells from the Atlantic Ocean to the hills, then sinks into the highly picturesque valley of Connecticut, and again rises into the mountainous region of Berkshire. The principal mountains are a part of the Green Mountain range, which stretches from N. to S. through the western part of the state. The most elevated summits of this ridge are Saddle Mountain, near the north-western angle of the state, and Tahconick on the western border. These mountains present a great variety of beautiful and impressive scenery, noble elevations alternating with dark green forests and pleasant well-sheltered valleys. Mount Tom and Mount Holyoke, near the Connecticut River, are striking elevations, and from their summits afford a beautiful prospect of the surrounding country. A second ridge passes through the state near its centre. The greatest elevation of this ridge is that of Wachuset, in the town of Princeton. The state abounds in small lakes, which are generally called *ponds.* The largest of these are the Assawamset and Long Ponds in Middleborough, Podunk and Quabaug Ponds in Brookfield, and the Naukheag Ponds in Ashburnham. The last-named are situated more than 1100 feet above the level of the sea, and several other ponds in the western part of the state have a still higher elevation. Massachusetts has no very large rivers wholly within its bounds. The Connecticut traverses it from N. to S., and is navigable by steamboats of 12 feet draught, above 30 miles from its mouth. The Merrimac passes out of New Hampshire into the northern division of the state, and empties itself into the sea at Newburyport. The Housatonic, Charles, Ipswich, Concord, Blackstone, Miller's, Chickopee, Deerfield, Westfield, Neponset, and Taunton, though they have short courses, are pleasant streams. Indeed no country is better provided with rivers and streams, which flow in all directions, and afford abundance of water for every necessary purpose. The rivers abound in falls admirably adapted for mill sites.

Every product which the northern states furnish, and much that is not indigenous to the soil and climate, have been naturalized in Massachusetts by skill and careful cultivation. The principal productions are Indian corn, rye, wheat, oats, barley, peas, beans, buckwheat, potatoes, hops, and hemp. Beef, pork, butter, and cheese, are abundant in most parts of the state, and of excellent quality; the county of Berkshire, in particular, is distinguished for its extensive dairies. There are fine orchards in many parts of the state. The fruits principally cultivated are apples, pears, quinces, plums, cherries, and currants. Peaches are also cultivated to a considerable extent, but they are generally of an inferior quality to those produced further south,—the principal towns in the state being chiefly supplied with that delicious fruit from New York and New Jersey. Great quantities of cider are annually made, and this formerly constituted the common beverage of the majority of the inhabitants.

There are several valuable mines in Massachusetts. Bog-iron ore is found in several parts, and there are many establishments for working it. In Southampton, Hampshire county, there is a lead mine, to which a subterranean passage of about 900 feet through solid rock has been made; but it has not been wrought for many years, owing to the facility with which the article is obtained from mines in the west, especially from Missouri. There are inexhaustible quarries of marble and limestone, and an abundance of granite of the best description for building. Soapstone, slate, ochre, and other mineral productions, are also to be met with in various parts.

Massachusetts.

A greater number of persons are engaged in commerce in this than in any other state in the Union. It shares in the greater proportion of the bank and whale fisheries of the United States. In this branch of industry many thousands of men are employed. The shipping is more extensive than that of any other state; and in the importance of its foreign commerce Massachusetts is second only to New York. The principal articles of export are,—fish, beef, pork, lumber, ardent spirits, flax-seed, whale-oil, spermaceti, and various manufactures, as those of cotton cloth, boots and shoes, leather, cordage, wrought and cast iron, nails, woollens, straw bonnets, hats, cabinet-work, paper, oil, and muskets. There is an extensive national establishment for the manufacture of arms at Springfield.

There being no very large rivers in Massachusetts to facilitate intercourse far into the interior, a number of canals were undertaken about the beginning of the present century; but since the introduction of railroads these have sunk into insignificance, and are almost entirely disused. There was the Middlesex Canal, of about 37 miles in length, connecting Boston Harbour with the waters of the interior of New Hampshire. Around the falls in Connecticut River, called Turner's Falls, at South Hadley, there is a canal cut through solid rock, more than 40 feet deep and 300 feet long. Other falls on the Connecticut, above and below South Hadley, have been obviated by canals, dams, and other improvements, which make the river navigable for boats throughout the whole of its course in this state, and as far as Bath in New Hampshire. The Blackstone Canal extended from Providence in Rhode Island to Worcester in this state, about 45 miles S.; but it has now been rendered almost, if not quite useless, by a railroad nearly upon the same line, completed a few years since. The Farmington Canal extends from the city of New Haven in Connecticut to the S. line of Massachusetts, there connecting with the Hampshire and Hampden Canal, which extends to Northampton on the Connecticut River, a distance of about 35 miles.

The railroads of Massachusetts are the most striking feature of internal improvement which the state presents. Of these, in 1856 there were within its limits 1450 miles. The most important are,—the Western 156 miles, Boston and Maine 83 miles, Old Colony and Fall River 87 miles, Vermont and Massachusetts 77 miles, Norwich and Worcester 66 miles, Fitchburg 68 miles, Boston and Worcester 68 miles, Boston and Providence 55 miles, Boston and New York Central 75 miles, Boston and Lowell 28 miles, Worcester and Nashua 46 miles, Providence and Worcester 43 miles, Connecticut River 52 miles, Eastern 60 miles, Cape Cod 47 miles, Cheshire 54 miles, New Bedford and Taunton 21 miles, Salem and Lowell 17 miles, Nashua and Lowell 15 miles. The lengths of the roads here given include the branches. Their construction, together with the equipments for running cars upon them, cost about L.12,000,000.

The colleges in Massachusetts are,—Harvard University at Cambridge, founded in 1636; Williams at Williamstown, founded in 1793; Amherst at Amherst, founded in 1821; Holy Cross, Worcester, founded in 1843; Tuft's College, Somerville, founded in 1854. All of these are Protestant institutions, except the Holy Cross, which is Catholic. Harvard College has a library of upwards of 100,000 volumes; Amherst has about 20,000 volumes. At Andover there is a well endowed theological institution. Academies and other schools for advanced pupils are found in all the principal towns in the state. No less important are the common town schools, established by law, which requires that every town and district containing fifty families shall be provided with a school or schools equivalent in time to six months for one school in a year; one containing a hundred families, twelve months; and so on: and the several towns in the state are authorized and required to raise such sums of money as are necessary for the support of the schools, and to assess and collect the money in the same manner as other town taxes. The schools are under the supervision of a school committee, chosen annually by each town. These committces consist of from three to seven persons. In 1855 the amount raised by taxation for the support of schools was about L.237,000, and the number of schools was 4215. There is a school fund, which, in the end of the same year, amounted to about L.338,750. The interest of this fund is annually distributed among the towns. The number of incorporated academies in the state is seventy-one, for the support of which there are local funds of about L.135,000.

Slavery has not existed in Massachusetts since the Revolution. The Supreme Court of the state decided in 1783, that as, by the declaration in the Bill of Rights, "all men are born free and equal," slavery could not exist under it. This was a virtual abolition of slavery in Massachusetts, and there has never been any disposition among the inhabitants to restore it.

From the census, bearing date, June 1, 1855, the population of Massachusetts as shown at that time, was 1,133,123. The state is divided into fourteen counties, the names and population of which follow:—Barnstable, 35,877; Berkshire, 52,791; Bristol, 87,425; Dukes, 4401; Essex, 151,167; Franklin, 31,655; Hampden, 54,852; Hampshire, 35,485; Middlesex, 194,082; Nantucket, 8064; Norfolk, 94,448; Plymouth, 61,513; Suffolk, 171,818; and Worcester, 149,545. Included in the population, there are about 9000 negroes, or persons of colour. They are scattered all over the state, but reside chiefly in the cities or populous towns. There are now in the state thirteen cities. These, arranged according to the dates of their charters, are as follow, together with the populations in 1855:—Boston (county of Suffolk), 160,508; Salem (Essex), 20,933; Lowell (Middlesex), 37,553; Roxbury (Norfolk), 18,477; Cambridge (Middlesex), 20,473; Charlestown, (Middlesex), 21,472; New Bedford (Bristol), 20,389; Worcester (Worcester), 22,286; Lynn (Essex), 15,713; Newburyport (Essex), 13,357; Springfield (Hampden), 13,788; Lawrence (Essex), 16,114; Fall River (Bristol), 12,680. The towns containing 5000 inhabitants and upwards are,—Chicopee, Adams, Pittsfield, Attleborough, Taunton, Beverly, Gloucester, Haverhill, Marblehead, South Danvers, Northampton, Newton, Somerville, Waltham, Woburn, Nantucket, Abington, North Bridgewater, Plymouth, Dedham, Dorchester, Quincy, Randolph, Weymouth, Blackstone, Fitchburg, Milford, and Chelsea.

The aggregate value of the products of the state, for the year 1855, is L.61,629,310. This amount is thus divided among the different counties:—

Barnstable.....	L.644,259	Principal products from the mackerel and cod fisheries.
Berkshire...	2,657,555	Do. Manufacture of woollen goods.
Bristol.......	6,110,078	Do. Sperm and whale oil.
Dukes........	158,798	Do. Sperm candles and oil.
Essex.........	8,301,671	Do. Boots and shoes.
Franklin....	1,049,635	Do. Horses, oxen, cows, and calves.
Hampden...	2,525,093	Do. Manufacture of cotton goods.
Hampshire..	1,463,100	Do. Horses, oxen, cows, and calves.
Middlesex...	12,126,174	Do. Cotton goods.
Nantucket...	335,167	Do. Sperm candles and oil.
Norfolk	5,050,845	Do. Boots and shoes.
Plymouth ...	2,684,313	Do. Boots and shoes.
Suffolk.......	10,039,366	Do. Clothing.
Worcester...	8,483,256	Do. Cotton goods.

There were at the commencement of the present year (1857) 172 banks in the state, with L.22,148,063 capital; of these thirty-six were in Boston, and contained above one-half of the whole banking capital of the state.

The first permanent settlement made in Massachusetts, was by a small colony of English, not numbering above one hundred and two persons, men, women, and children. They came in the inclement month of December, in the year 1620, and landed in a desolate and barren place, to which they gave the name of Plymouth. Eight years after, a second settlement was effected in another part of the coast. The place of this settlement was called Salem. There were indeed other attempts at settlements between 1620 and 1628, but they either failed, or were so inconsiderable as to be overlooked in a general view, as was the case at the point afterwards called Boston, and an adjacent island. Two years after the settlement at Salem, however, a large company of emigrants arrived, and occupied the district where Boston now stands. The settlers of Plymouth had fled to this country that they might enjoy their peculiar religious sentiments without molestation. This is partially true with respect to those who settled in Salem and Boston. Massachusetts did not originally include Plymouth, which was a separate colony, had its patent, and was governed by its own laws. The Massachusetts charter was annulled by the king in 1686. In 1692 the two colonies were united in one, and governed by a viceroy until the year 1776, when the American colonies were separated from Great Britain.

The constitution of the state of Massachusetts was formed in 1780, and revised in 1820. Amendments of minor importance were made in 1831, 1833, 1837, 1840, and 1855. As a form of government it is substantially the same now as it was when originally formed. The legislative power is vested in a Senate and House of Representatives, which together are styled the "General Court of Massachusetts." The General Court meets annually at Boston on the first Wednesday of January. The Senate consists of 40 members who are chosen by districts annually. The House of Representatives consists of from 300 to 400 members who are elected annually. By the amendment of the constitution adopted in 1840, every corporate town having 1200 inhabitants is entitled to one representative; larger towns are entitled to as many additional representatives as the number 2400 is contained times in the number of its inhabitants over 1200. Smaller towns are entitled to one representative as many times in ten years as the number 160 is contained in the number of its inhabitants; and also one representative on the year in which the valuation of property is taken, being every tenth year. For the purpose of being more frequently represented, towns having less than 1200 inhabitants each may unite themselves into districts, and then be entitled to be represented in proportion to the population of the districts. As the population of the state increases, a greater number of inhabitants is required as the basis of representation in accordance with a sliding scale.

The governor or chief magistrate is elected annually by the people, and is assisted in his office by a council of eight members, also elected annually by the people, voting in districts, each district being entitled to one councillor.

The right of suffrage is granted to every male citizen twenty-one years of age (except paupers and persons under guardianship), who has resided within the commonwealth one year, and within the town or district in which he may claim a right to vote, six calendar months immediately preceding any election, and has paid a state or annuity tax assessed upon him within two years preceding such election; and also to every citizen who may be by law exempted from taxation, and who may be in all other respects qualified as above mentioned. Further amendments of the constitution are in contemplation, and have already received the sanction of the legislatures of 1856 and 1857, and require nothing more for their final adoption but the sanction of the popular vote. By one of these, the number of members of the House of Representatives is to be reduced to 240, who are to be chosen in districts, and the right of representation is to be in exact proportion to population. By another, the ability to read and write is to be added to the qualifications necessary for the right of suffrage.

The judiciary power is vested in courts established by the legislature, and in justices of the peace. The judges of the courts and the justices of the peace are appointed by the governor with the consent of the council. The former hold their offices during good behaviour; the latter for seven years. The supreme judicial court, as at present established, consists of six judges. It has original and exclusive jurisdiction in the trial of all capital offences, and in all cases of divorce and alimony; with few trifling exceptions, it has original and exclusive jurisdiction of all civil causes in which relief is sought in equity; also in all real actions, except for the foreclosure of mortgages. In the county of Suffolk it has jurisdiction concurrently with the superior court of the county of Suffolk, in all actions at law except real actions in which the amount in controversy exceeds 3000 dollars (L.625); and in the other counties concurrently with the court of common pleas, in all such actions where the amount in controversy exceeds 300 dollars (L.62, 10s.). It has appellate jurisdiction in all matters heard in the probate court. It has a general superintending power over all inferior tribunals; and all questions of law determined in any of them, where there is no right of appeal upon the facts, may be brought into this tribunal by writ of error, bill of exceptions, or otherwise, and reheard. In trials of actions at law before a jury, and in hearings of questions of fact on probate appeals in matters of equity, and in cases of divorce and alimony, the court is held by a single judge; but in capital trials, and in the hearing of all questions of law brought from the inferior tribunals, or on exceptions taken to the ruling of a single judge of its own bench in any matter tried before him, the court is held by not less than three judges, and usually by a full bench.

The superior court of the county of Suffolk consists of four judges. It has civil jurisdiction in the county Suffolk, concurrently with the supreme judicial court in all actions at law except real actions, when the amount claimed exceeds 3000 dollars. It has exclusive jurisdiction in all such actions where the amount claimed is less than 3000 dollars and more than 100 dollars (L.20, 16s. 8d.); and jurisdiction concurrently with justices of the peace when the amount claimed is less than 100 dollars and more than 20 dollars (L.4, 3s. 4d.). It has jurisdiction in all cases of crimes not capital, except breaches of the peace, trifling assaults, larcenies of small amount, and other slight offences. It has appellate jurisdiction of all cases tried before justices of the peace. The court of common pleas consists of seven judges. It has in the other counties the same jurisdiction which the superior court of the county of Suffolk has in that county; except only that in actions at law it has jurisdiction concurrently with the supreme judicial court in all actions in which the amount claimed is more than 300 dollars (L.62, 10s.). Justices of the peace have civil jurisdiction concurrently with the superior court and court of common pleas, in cases where the amount claimed is more than 20 and less than 100 dollars; and exclusive jurisdiction where the amount claimed is less than 20 dollars. They have criminal jurisdiction in cases of breaches of the peace, trifling assaults, larcenies of small amounts, and other slight offences. In all cases tried before them there is a right of appeal. In the city of Boston, and in several other cities of the commonwealth, there are established police and justice courts; with the jurisdiction of justices of the peace in other places.

There is in each county a probate court, having jurisdiction in the probate of wills, settlements of estates of deceased persons, and guardianship of minors, idiots, lunatics, and others. There is also in each county a court of insolvency, having jurisdiction in cases of insolvent debtors, and the settlement of their estates. (S. S. D.)

MASSAFRA, a walled town of Naples, in the province of Otranto, 10 miles N.W., of Tarento. The town is picturesquely situated on the slope of a hill, and the houses stand on the very brink of a rocky chasm through which a stream has worked its way and hollowed out the sides into many fantastic shapes. Massafra is supposed by some to be the ancient Messapia; but this is called in question by others. Pop. about 7000.

MASSAROONY, or MAZARUNI, a river in British Guiana, rises in Lat. 4. 30. N., Long. 60. W.; and flows in a very irregular and circuitous course, generally N.E., till it joins the Cuyuny, and falls into the estuary of the Essequibo. This river has been explored for about 400 miles from its mouth; its course is interrupted by numerous rapids, which are generally divided by blocks of granite into many separate streams. In the lower part of its course it contains numerous small islands. The scenery of its upper course is mountainous, consisting of bold perpendicular granite cliffs.

MASSENA, ANDRÉ, Prince of Essling and Marshal of France, was the son of a wine-merchant, and was born at Nice in 1758. At an early age he enlisted into the French service as a private in the Royal Italian regiment, but after having served fourteen years without rising higher than an inferior officer, he retired disheartened from military life. The French Revolution, however, reanimated his warlike ambition, and in 1792 he was appointed to the command of a battalion of the national volunteers of Var. As his valour and talents had now fair scope, his rise was rapid. In 1793 he was appointed general of brigade, and in 1795 he commanded the right wing of the army in Italy as general of division. In this capacity he acted no mean part "at the terrible bridge of the Lodi," and for his brilliant repulse of Beaulieu at Roveredo, he earned from his commander-in-chief, Napoleon, the surname of "the favourite child of victory." So marked was his conduct at the battle of Rivoli in 1797, that he afterwards received the title of *Duc de Rivoli;* and so high had he now risen in the estimation of Bonaparte, that he was despatched to France by that general to present to the Directory the ratification of the treaty of peace with Austria. In 1798 Massena was entrusted with the invasion of the States of the Church, but being accused by his soldiers of avarice, he was forced to lay down his command soon after his appointment. Receiving, however, in the following year, the command of the army in Switzerland, he defeated the Russians at Zurich, and thus saved France from the invasion of the allied armies of Russia and Austria. On the return of Napoleon from Egypt in 1800, Massena was sent to consolidate the shattered remains of the Italian army, and to check the successes of Austria. With a mere handful of troops, and with little ammunition, and less provisions, he threw himself into Genoa, and resisted the beleaguering Austrians, until he was compelled by famine to yield to an honourable capitulation. A few days after this Bonaparte routed the enemy at Marengo, and Massena was replaced in his command. But grasping cupidity was again the cause of his disgrace, and he was soon afterwards superseded by Brune. Massena, however, possessed a military genius that could not be spared in those troublous times. He was therefore created a marshal of France in 1804, and in the following year was once more appointed to the command of the army in Italy. After opening the campaign by the capture of Verona, he received several severe checks from the Austrian army under the Archduke Charles. Yet when the enemy retreated from Italy, Massena hung upon his rear, and ultimately effected a junction with the grand army of Napoleon. In 1806 Massena was commissioned at the head of a large army to accompany Joseph Bonaparte to his new kingdom of Naples. From Italy he was summoned in 1807 to command the right wing of the French army in Poland. But his military genius was chiefly conspicuous in the Austrian campaign of 1809. He saved the French army at Essling by his desperate defence of the village of Aspern, and his directing skill and animating bravery contributed in no small degree to the decisive victory of Wagram. For these services Bonaparte conferred upon him the title of Prince of Essling, and loaded him with riches and honours. As the reputation of Massena became greater, it was submitted to greater tests. Accordingly in 1810 he was chosen by Napoleon to stop the advance of Wellington in Portugal, and was commissioned "to drive the English and their sepoy general into the sea." But the wary strategy and imperturbable firmness of the British general proved resistless, and Massena was compelled to save his military fame by a masterly retreat. Ill in health, and chafing under disappointment, Massena retired to his native Nice, and was not again entrusted with a post until 1813. He was then appointed to the command of the Eighth Military Division at Toulon. In 1814 he sent in his submission to Louis XVIII., and was in return confirmed in his appointment, and created Commander of the Order of St Louis. With some reluctance he transferred his allegiance to Napoleon on his return from Elba, and he remained inactive during the Hundred Days. After the disaster at Waterloo he again submitted to the Bourbons, and was appointed commander of the national guard. Marshal Massena died in April 1817.

MASSILIA (the modern *Marseille*), a Greek town of Gallia Narbonensis, on the S. coast, was situated on a rocky peninsula E. of the mouth of the Rhone. It was founded by a colony of Phocæans, from the Ionian confederation in Asia Minor, upon a site granted to them by Nannus, king of a Ligurian tribe. The settlers were commanded by Simos and Protis, according to Justin, or by Euxenus, the father of Protis, according to Aristotle. The date of the settlement is uncertain. Encompassed on all sides by lawless barbarians, the Massaliots were often assailed both by stratagem and by open violence. Yet they not only defended themselves with success, but gradually extended their territory, and in no long time had planted along the coast several colonies, such as Antipolis (*Antibes*), Nicæa (*Nice*), Agatha (*Agde*), and Emporiæ (*Ampurias*). The sterility of their soil forced them to become a commercial people, and as their well-sheltered town formed a commodious port for vessels, they speedily acquired both wealth and influence. Accordingly, on the outbreak of the second Punic war in 218 B.C., Massilia was of sufficient importance to be received into the alliance of Rome. It was a faithful and useful ally to Cæsar during all his Gallic campaigns. Adopting, however, the cause of Pompey at the commencement of the civil war, the town was besieged by Cæsar; and after a long and stubborn resistance it was compelled to capitulate, and deliver up all its ships, military equipments, and public money. From this period Massilia, though it retained its independence, began gradually to decline. The growing importance of the Roman colony, Narbo Martius (*Narbonne*), probably affected its commercial prosperity. It however acquired a new importance as the school where the neighbouring Galli studied rhetoric and philosophy; insomuch, that in the reign of Augustus and Tiberius it came to be considered the Athens of the West, and among many other Roman youths, Agricola, the conqueror of Britain, was educated there. After the time of Cæsar the history of Massilia comprises no event of interest.

The Massaliots were noted for their simplicity, temperance, and virtue. Their government was aristocratic, and consisted of 600 dignitaries called Timuchi. A committee of fifteen chosen from these held the administration and delegated the executive power to three of their own number.

MASSILLON, JEAN BAPTISTE, one of the greatest pulpit orators of France, was the son of François Massillon, a notary of Hières in Provence. He was born on the 24th of June 1663, and entered, when very young, into the College of the Oratory in that city. Having been destined by his father for the profession of a notary, he was early withdrawn from college; but as he never ceased to return thither at his leisure hours, the superiors, remarking his dispositions, addressed solicitations to his father, in order to obtain his permission to attach the youth to themselves; and, in the year 1681, young Massillon entered the congregation, where he studied theology under Father Beaujeu, afterwards Bishop of Castres. In the year 1689 he wrote to Father Abel de Sainte-Marthe, general of the Oratory, that, as his talents and his inclination equally disqualified him for the pulpit, he conceived that some employment in teaching philosophy or theology would suit him better. Nevertheless, having been ordained priest, some panegyrics preached by him determined his superior to direct his talents to the ministry of the pulpit. After having professed the belles-lettres and theology at Pézenas, Montbrison, and Vienne, and after delivering some funeral orations, he was in 1696 called to Paris, to assume the direction of the seminary of Saint-Magloire. It was there that Massillon composed his first ecclesiastical Conferences, which are characterized by so much simplicity and vivacity. He was an ardent admirer of Bourdaloue; but he did not regard him as a model in everything, because he wished to open a new path for himself. Massillon observed that the preachers of his day were too much occupied with external manners, or vague and general moralities; and he resolved to search in the heart of man for the secret workings of the passions, in order to discover their motives, and combat the illusions of self-love by reason and sentiment, as well as by the attraction of happiness united to religion. Such was the distinctive character of his eloquence. In 1698 he went to preach during Lent at Montpellier, where he was warmly received, notwithstanding Bourdaloue had not been forgotten. Being now known, he could no longer fly from his renown, which soon recalled him to the capital. In 1699 he preached during Lent at Paris, in the church of the Oratory, and obtained a triumph which would have intoxicated a preacher who had less self-knowledge, with, perhaps, greater pretensions to humility. On a particular occasion, being congratulated by one of his brethren on the admirable manner in which he had preached; "Stop, Father," said he; "the devil has already told it me more eloquently than you." Massillon appeared in the pulpit with downcast looks, without gesture, and without parade. Nevertheless, when he warmed with his subject, his look and gesture became so expressive, that Baron, the celebrated actor, having gone to hear him, was so much struck with the correctness of his delivery, that he observed to one of his companions, "My friend, here is an orator; but as for us, we are only actors."

Being appointed preacher to the court at Versailles for the advent of 1699, the father of the Oratory appeared there without pride and without timidity, and produced such a powerful impression on Louis XIV., that he addressed to him, in presence of the whole court, the words, "Father, I have heard several great orators, and I have been satisfied with them; but as for you, whenever I hear you, I am dissatisfied with myself." The language of Massillon, though noble, was not the less simple, and adapted to the comprehension of the humblest; it was always natural and just, without labour and without affectation, and hence it had equal attractions for persons of all classes. The first time that he delivered his celebrated sermon on the small number of the elect, was at Saint-Eustache, when the whole auditory rose up, in the midst of the peroration, at once transported and dismayed. This prosopopœia, which still astonishes in the perusal, has been chosen by Voltaire in the article *Eloquence* in the *Encyclopédie*, as an example presenting "la figure la plus hardie, et l'un des plus beaux traits d'éloquence qu'on puisse lire chez les anciens et les modernes." In 1704, when Bossuet and Bourdaloue were both removed by death, Massillon preached a second Lent at court, and with such success that Louis XIV. expressed a desire to hear him every two years; but from whatever cause, he never again appeared in the pulpit of Versailles, until he pronounced the funeral oration of the king in 1715. In 1709 he likewise delivered the funeral sermon of the Prince of Conti, in the church of Saint André-des-Arc, which was much applauded when delivered, though sharply criticised after it had been printed. After more than twenty years spent in preaching, Massillon, promoted by the regent to the bishopric of Clermont, in 1717, was appointed to preach before the king during Lent. This was his last effort, but it is also his masterpiece. Massillon had nearly attained his fifty-fifth year when he composed his *Petit-Carême*, which made him be called the Racine of the pulpit. In these discourses refined views and delicate touches of humanity compensate, by elegance and grace of expression, for the bolder ornaments and deep pathos of his ordinary style. An eloquence more gentle and more insinuating, because intended to make an impression upon a young prince, thus forms the characteristic of the *Petit-Carême*. Voltaire himself, on more than one occasion, transfused several passages from one of these discourses into his own verses, and had the *Petit-Carême* always on his desk, regarding it as one of the best models of prose eloquence. In the year 1719 he was received into the French Academy. But he was far from being dazzled by these honours, and soon set out for his diocese, which he only left in 1721 to pronounce at St Denis the funeral oration of the Duchess of Orleans. Following the advice of Cardinal de la Rochefoucauld, Massillon prepared his episcopal *Conférences*, so full at once of earnestness and severity. His *Discours Synodaux* and his *Mandements* are grave instructions, conveyed in language remarkable for simple and natural elegance. The conduct of Massillon, as a pastor and bishop, corresponded to his zeal. All his actions were characterized by a wise and amiable moderation. He was eminently charitable and humane, and was always ready to raise his voice or use his purse in behalf of the poor or the oppressed. In a word, his whole life was a practical commentary on the divine precepts which he had so eloquently enforced; and he died, as he had lived, breathing sentiments of the most exalted piety, on the 18th of September 1742. The nephew of Massillon published a good edition of his uncle's works, in 14 vols. Paris, 1745–46. Of the more recent editions, we may mention those of Méquignon, 14 vols. 8vo, 1818; of Besançon, Chalandre and Son, 3 vols. large 8vo, 1847, which contains various pieces never before published. The *Eloge de Massillon* by D'Alembert was read to the French Academy in 1774, and printed in the first volume of the History of the Academy in 1779. The reader may also consult the *Principes* and the *Essai sur l'Eloquence de la Chaire* of the Abbé Maury, and the *Cours de Littérature* of Laharpe. (J. B—E.)

MASSILLON, a town in the county of Stark, state of Ohio, North America, on the left bank of the Tuscarawas River, which is here crossed by a handsome stone bridge, 112 miles N.E. of Columbus. The town is regularly and substantially built, and contains many fine stone edifices. The neighbourhood of Massillon is a rich agricultural district; and the town is, in consequence, a great emporium for the produce. The manufactures are also considerable; and iron-ware and flour are the chief products. The annual value of the exports and imports is calculated to amount to above L.1,000,000. Pop. (1853) 4000.

MASSINGER, Philip, an eminent dramatist of the age of Shakspeare, was the son of Arthur Massinger, a gentleman in the service of the Earl of Pembroke, and was born at Salisbury in 1584. It has been conjectured that he received his early training at Wilton, the Wiltshire seat of the Pembroke family. But a more likely opinion is, that he was educated in his native city, at that school which afterwards numbered Addison among its pupils. In May 1602 he was sent to Oxford, probably at the charge of the Earl of Pembroke, and was enrolled a commoner of St Alban's Hall. There, according to Anthony à Wood, he eschewed the severe studies of logic and philosophy, and pleasantly squandered his hours in reading poetry and romance. Before he had completed the round of studies necessary for a degree, he was forced abruptly to leave the university, on account, as is generally believed, of the withdrawal of his patron's supplies. Of this withdrawal different explanations have been given. Gifford solves the difficulty by imagining, from certain passages in *The Virgin Martyr*, that Massinger was a Roman Catholic, and by unwarrantably inferring from this that he changed his faith at Oxford, and thus displeased his patron. Equally unsatisfactory is the explanation of Davies, who ascribes the event to Massinger's misapplication of his time. For it is by no means probable that William, the third earl of Pembroke, a man of a generous and liberal disposition, and a well-known patron of poets, and especially of dramatists, would cast the son of an old servant of his family penniless upon the world, simply because he devoted his attention to literature. There must evidently have been a more grievous cause of offence.

From Oxford Massinger repaired to London in 1606, where he devoted his life to the cause of the drama, and became the fellow-worker and rival of such men as Shakspeare, Jonson, and Fletcher. His biography, after this period, is little else than an account of the dates at which his principal plays were written. We know, however, that he toiled on in a modest privacy till the day of his death, producing two or three plays in a year, struggling at the same time in the gripe of poverty, and living unknown and neglected even while his admirable productions were calling forth the applause of the theatres. There is still extant a letter in which he requests Henslowe, a theatrical manager, to rescue him from a pecuniary difficulty. So often, indeed, was he in extreme destitution, that in dedicating one of his plays, he says, "I had not to this time subsisted, but that I was supported by your frequent courtesies and favours,"—an acknowledgment which on some similar occasions he makes in nearly the same words. How Massinger was engaged immediately after his arrival in London is not recorded. Urged by daily necessities, and afraid of risking his valuable time on a work of his own, he was probably content to be employed in assisting dramatists of an established fame. It is certain at least, that about 1613 he had been engaged as a joint-author with Fletcher, Field, and others. At first he was compelled to labour submissively under the shadow of some great dramatist, and to content himself with little of the profits, and less of the fame derived from their joint productions. In course of time, however, when his genius had asserted its proper place, other play-writers became desirous of having his name conjoined with their own on the title-pages of their works. Accordingly, at some period before 1623, he appeared before the public as the joint-author of *The Virgin Martyr* along with Decker, of *The Fatal Dowry* along with Field, and of *The Old Law*, along with Middleton and Rowley. Meanwhile he had written several plays by himself. Of these *The Unnatural Combat* and *The Duke of Milan* alone are extant. The rest, along with a few others of Massinger's plays, were preserved for some time in manuscript by a Mr Warburton, only to be devoted at last by that gentleman's cook to the covering of pies. *The Unnatural Combat* is full of vigour and passionate eloquence; and its plot, though marred by many disgusting incidents, retains evident traces of a master's hand. With many passages full of lofty poetical sentiments, and with an action deeply engrossing in its progress, and horror-striking in its catastrophe, *The Duke of Milan* is one of the best of Massinger's tragedies. The character of Sforza is a vivid representation of that impulsive temperament which fluctuates with the rapidity of thought between the most opposite passions. In 1623 *The Bondman* was produced at the Cockpit in Drury Lane. Its chief interest arises from the variety of its *dramatis personæ*. *The Roman Actor*, which was licensed in 1626, is not generally thought to be what its author styled it, "the most perfect birth of his Minerva." More popular and more successful, both in plot and execution, was *The Great Duke of Florence*, produced in 1627. About this time Massinger wrote his most famous play, *A New Way to Pay Old Debts*. Its principal character, Sir Giles Overreach, intended for a satire against an infamous public individual of that day, is one of those rough, strongly-marked, and one-sided creations that are peculiarly fitted to carry the popular taste by storm. Accordingly, this comedy is said to have been a great favourite "at the Phœnix in Drurie Lane," and is the only one of Massinger's plays that still keeps possession of the stage. Of the rest of its characters, Marrall, the mean-spirited yet revengeful time-server, is the most amusing and most ably drawn. In 1629 was acted *The Picture*, one of the most pleasing of its author's productions. To a plot original and romantic, is added the stronger charm of a strain of feeling tender and poetical. The more earnest sentiments of the play are pleasantly relieved by the healthy, cynical humour of Ladislaus, and the spirited practical jokes of Sophia. Equally fresh and varied is *The City Madam*, licensed in 1632. It is a satirical sketch of the ridiculous airs and blind prodigality of upstart wealth. The numerous objects in the picture are artfully grouped and strongly coloured. *The Bashful Lover* was acted with great applause at the Blackfriars in 1636. Its principal charm arises from the chivalrous love and valour of Hortensio. The other extant plays of Massinger are,—*The Renegado*, *The Parliament of Love*, *The Maid of Honour*, *The Emperor of the East*, *The Guardian*, and *A Very Woman*. The continuous toil undergone in producing so many works seems to have imperceptibly undermined the health of Massinger. On the night of the 17th March 1640 he went to bed in apparent good health, in his own house on the Bankside, and was found dead next morning. His body was attended by the comedians to the churchyard of St Saviour's, and the sad story of his obscure life and lonely death was told in the register of his interment: "March 20, 1639-40, buried Philip Massinger, a stranger."

In his graphic delineation of character, in his skilful management of a plot, and in the blended grace and dignity of his blank verse, Massinger yields to none but Shakspeare. Less pathetic and less imaginative than a few of the secondary dramatists, he is also more refined and more melodious than them all. His besetting sins are a fastidious attention to the evolving of his catastrophe, and a consequent tendency to impair the consistency of his personages by adapting them to circumstances. Yet his incidents, though laboured, are ever fresh and engrossing, and his portraitures of character, though indistinct in their minuter traits, are strikingly bold and vigorous in their outlines. His comedies are deficient in humour. They are, however, of great value as accurate and interesting life-sketches.

Regarding Massinger's personal character, we can infer from the panegyrics affixed to his plays, that he was amiable, gentle, and reserved. The dedications of his several works to his patrons also throw some light on this subject. In these we see the instincts of a true and noble nature leading him in the middle path between a mere formal expression of gratitude and a slavish adulation. Nothing can be finer than the modest and manly simplicity with which he on several occasions records in one brief sentence his own destitution and the beneficence of his noble friends. The best edition of the works of Massinger is that of Gifford, published in 1805, and reprinted in 1815. An edition, freed from all objectionable passages, forms three volumes of Murray's Family Library, London, 1830.

MASSOUAH, Massowah, or Masuah, the most important seaport of Abyssinia, is situated on an island in the Red Sea, and separated from the mainland by the channel of Adowa, 250 miles N.E. of Gondar. The island is about half a mile in length by a quarter in breadth; and about one-third of it is covered with houses. Although some of the houses are built of stone, most of them are mere huts made of poles and grass. The only buildings of any importance are the mosques. The harbour is deep and secure, and can accommodate about fifty vessels; and though the entrance is narrow, access is not difficult. Owing to the dry and rocky nature of the island, water has to be collected in large tanks, which cover about one-third of the area. Massouah has a very important trade. It is not only the principal seaport in Abyssinia, but also the largest emporium on the coasts of the Red Sea. The chief articles of export are,—slaves, horns, ivory, wax, coffee, leather, hides, butter, honey, grain, gold, and spices; while the exports consist of pepper, cotton, silks, muslins, razors, sword-blades, carpets, &c. Massouah belongs to the viceroy of Egypt, and a governor, subordinate to that dignitary, resides here. Pop. of the entire island estimated at 10,000.

MASTER AND SERVANT, a relationship constituted by mutual consent. Service or labour in this country is regarded as property, of which no one can be deprived against his will, unless he be convicted of crime, when the exaction of compulsory labour may form part of the punishment. Where a man voluntarily disposes of his labour, the law will enforce fulfilment of the contract, just as it enforces all other lawful contracts. Parties unqualified to give consent,—as, for example, pupils; that is, males under fourteen, and females under twelve years of age; or intoxicated, or insane persons,—cannot enter into such a contract; neither will the law regard the most formal contract, if it appear that it was extorted by force or fear, or was obtained by fraud. The existence of the contract may be proved by writing, or, within certain limits, by witnesses; and it may sometimes be inferred from circumstances. In Scotland, if the agreement is meant to last more than a year, writing is not only required, but it must be what is called probative writing, otherwise either of the contracting parties may repent of, and withdraw from the agreement; but if any intelligible writing, however informal, be followed by the mutual actings of parties under it, the law will regard it as obligatory. Earnest-money is not necessary, unless required by the established and uniform usage of any particular locality. When given, it is justly regarded as evidence of a concluded agreement, which the sending back of the earnest-money cannot undo. When the contract is once concluded, the parties must discharge the obligations which they have undertaken, and that personally, and not by substitution. The duties to be performed, the recompense for these duties, and the duration of the contract, are matters of arrangement. Sometimes local customs supply ambiguities in a contract, but they never prevail against express stipulations. Dishonesty or open immorality, wilful disobedience or habitual negligence or disrespect, justifies the dismissal of a servant without wages, at whatever period of the contract such an offence occurs, because the wages are not legally earned until the covenanted term of payment arrives. Excessive labour cannot be demanded from servants; nor are they bound to work at anything which is unlawful, or substantially different from, or of a decidedly lower kind than that for which they were hired. They are not bound to work on Sunday unless they be domestic or farm servants, and then it is only at such necessary work as that which from its nature requires to be performed every day. Masters are not liable in the consequences of injuries which servants may sustain while acting in obedience to reasonable orders, from which, with due care, no injury could have been anticipated. In such cases masters are not liable even for the expense of medicines or medical aid which the servant may require; though, whenever these are voluntarily provided by the master, he is not entitled to charge them against the servant. If a servant be injured through his master's unreasonable conduct or culpable neglect, the master is liable in damages to the servant, or to his heirs, if the injury terminate in his death. Complaints against the conduct of a servant must not be reserved as a set-off against payment of wages at the expiry of the contract, but must be made when they occur. A plea, for example, of incapacity or negligence against a servant is made too late when the termination of the contract has arrived and the wages have become payable; but faults complained of and pardoned till their repetition becomes intolerable, may be proved in justification of a master who at length is compelled to dismiss the servant. No servant is bound under any circumstances to submit to maltreatment at the hand of his master, nor even to such threats as create a reasonable apprehension of danger. Servants must, when required, accompany their master wherever he goes within the kingdom, provided he does not thereby do them any real injury, and agrees to bring them back in time to seek for another situation at the close of the contract; but not if they were hired with reference to a particular place or to special duties, such as to serve or work in a particular factory. Masters are under no legal obligation to give a character to any servant, and where a good one cannot truthfully be given, it is safer to give none; though, when a servant refers to his master for his character, he must take his risk of the answer, provided it be not false and malicious. If a master knowingly give a good character to an undeserving servant, he is liable to the succeeding master, by the law both of Scotland and England, in damages, and in England, by the 32d Geo. III., cap. 56, in a fine of L.20, or imprisonment with hard labour for not less than one, or more than three months. In a case in England, where a person gave a good character of a servant in the full knowledge that he was unworthy of it, and a succeeding master was thereby induced to take him into his service, and was soon thereafter robbed by him, for which the servant was tried and executed, Lord Mansfield held that the pursuer was entitled to recover the loss from the person who knowingly and falsely gave the good character. Even where a good character was honestly given, if it be afterwards discovered to have been undeserved, the master who gave it must notify the discovery to the person to whom he gave it. If a servant obtain a situation by false pretences, affirming that he served where he did not, or that he did not serve where he really did, or shall alter or erase a written character, he may be summarily dismissed, and in England is liable in a fine of L.20. We shall notice more particularly—

1. *Apprentices.*—They are distinguished from other servants in this respect, that they engage to serve their master in his particular trade or calling chiefly in order that they may learn it. Minors having no curators may enter into indentures; but if they have curators, their concurrence is necessary. Even then, the indentures may be set aside if they involve manifest and serious injury to the minor. Pupils, being legally incapable of consenting, cannot bind themselves. It is not unusual, however, for parents to bind themselves for their pupil children. The master, by himself, or a qualified overseer, must fairly instruct the apprentice in all the branches of his business, so far as the apprentice is capable and willing to be instructed, and not put him to any other employment, beyond that of teaching his fellow-apprentices the calling to which he is bound, as in doing so he improves himself. If a master die or retire from business during the currency of the indenture, the apprentice has no further claim than that another equally well qualified master be found in the same locality, to whom the indenture may be transferred; but no transference can be effected without the apprentice's consent. The bankruptcy of the master puts an end to the indentures, leaving the apprentice to rank on the master's estate for a proportion of the apprentice-fee, or damages. Changes in the constitution of a company, however, do not free the apprentice, provided one or more of the original partners remain to carry on the business. The articles of indenture generally specify a penalty against either party failing to perform his part of the contract, but the court will modify the penalty to the actual damage. As a master stands somewhat in the relation of a parent to an apprentice, he is not entitled to dismiss him for every trifling fault, but he may do so if, after warnings, the apprentice prove incorrigible or incapable, or if he commit a single act of dishonesty or gross immorality; and the master is not bound to take him back on promises of amendment, as his bad example may be pernicious to the master's other apprentices. Notwithstanding such an offer, the master may even sue for the penalty. Apprentices put to trade by a parish, or any others on whose binding no larger sum of apprentice-fee was paid than L.25, may, by the 20th Geo. II., cap. 19,—and apprentices on whose binding no sum whatever was paid, may, by 5th Vict., cap. 7,—be punished to the extent of a month's imprisonment, by two justices, for any ill behaviour, and to the extent of three months for desertion. But these statutes are understood to be confined to the particular classes of apprentices mentioned in them and in 17th Geo. III., cap. 56. Under these statutes masters who beat their apprentices improperly may also be punished. By the common law the enlistment of an apprentice does not destroy the indentures; but the statute 48th Geo. III., cap. 15, only enables the master to reclaim him, provided he is then under twenty-one years of age; that the apprenticeship was for four years; that the indentures were produced to, and indorsed by, a magistrate before the enlistment, and within three months after their date; and that the master claim the apprentice, and make oath before a magistrate, within one month after the enlistment.

2. *Workmen and Labourers.*—Unless a special agreement can be proved, the period for which they are engaged, their hours of labour, and even the amount of their wages, are regulated by the usages of their particular trade. If there be no general usage as to wages, a court of law will either fix what is reasonable, or remit the matter to a jury. The legal presumption is, that service must be remunerated. Ordinary workmen and labourers are generally presumed to have been hired by the day or week; and farm servants, gardeners, overseers, grieves, &c., by the year. In an action for wages by the foreman of a silk factory, Justice Park said (1833)—"The presumption is, that the plaintiff was hired for a year, and nothing being proved contrary to that presumption, and he having violated his duty before the year expired, so as to prevent the defendant from having his services for the whole year, he cannot recover wages,"—not even rateably for the time he has served, as the full term must be completed before wages are due. If servants work in their

own dwellings, they may retain the goods of their master, on which they have expended their labour, in security of their wages, but not if they work in their master's premises. On the bankruptcy of their master, farm servants and reapers have a preferable claim on his crop for their current wages; and their wages are not attachable for their debts so far as necessary for their subsistence. Provision is made by the statutes 22d Geo. II., cap. 27; 17th Geo. III., cap. 56, and 58th Geo. III., cap. 51, for the summary conviction and punishment of workmen in certain trades who purloin, embezzle, pawn, or sell their master's materials or tools; and neglect to return unused materials within eight days after demand, is held to be embezzlement. Amongst the trades referred to in these statutes are hatters and workers in woollen, linen, fustian, cotton, iron, leather, fur, hemp, flax, mohair, and silk, and workers in any of these materials mixed, and also dyers and hot-pressers. The knowingly purchasing or taking embezzled materials by any person from such workmen is severely punishable; and where such materials are found in the possession of the receiver, the burden is laid on him of proving that they came into his possession in a lawful manner. Under these statutes one justice of the peace may issue a warrant for the apprehension of accused parties, but two are required for conviction. An appeal lies to the next general or quarter sessions, on the party entering into recognisances, with security, to abide the result.

The statute 4th Geo. IV., cap. 34, provides that if any servant in husbandry, or artificer, calico printer, handicraftsman, miner, collier, kealman, pitman, glassman, potter, labourer, or other person under contract by a signed writing, shall not enter to, or having entered, though not under a written contract, shall absent himself, or shall be guilty of any other misconduct or misdemeanour in the execution of the contract, it shall be lawful to any justice of the peace of the place where such servant contracted, or is found, upon complaint on oath, to issue a warrant for apprehending him, and to examine into the complaint, and, if proved, to commit him to hard labour not exceeding three months, or to punish him by abating the whole or part of his wages. The provisions of this statute are, by the 10th Geo. IV., cap. 52, extended to all persons engaged, whether as servants, apprentices, or otherwise, in the several manufactures, trades, and occupations above named, alluded to in the statute of 17th Geo III., cap. 56. Under these statutes a workman of any of the classes above referred to may be punished if he produce an insufficient quantity of work, or be disobedient, or refuse to work, or desert. If he commit a higher offence than these—as, if he steal his master's goods or break into his premises—the offender may be prosecuted, as the law directs, in a higher criminal court. It is decided that these statutes do not apply to cases where the parties do not stand towards each other in the precise relation of master and servant; as, for example, if a master employ a workman to execute a specific piece of work for a gross sum, or if the employer by the contract have no title to require the workman to work at any particular time or place, but only that the work shall be done within the covenanted period. In such cases it would be competent to the workman to accept simultaneously of any other employment from other individuals, so that he could not strictly be termed the servant of any particular master. Accordingly, in England it was found that a contract to build a wall for a given sum, within a specified time, did not bring the workman within the statutes; Justice Park remarking, that to do so, there must be a contract for service exclusively to one employer. The words "or other persons" are added to the specification of servants given in the statutes, and it is often difficult to determine to whom they refer. They do not refer to menial or domestic servants, but to persons hired for out-door or country labour, and generally to all who, by the rules of any particular trade, must give a definite warning before they are entitled to quit their master's service. Complaints under these statutes do not require the concurrence of any public prosecutor. They usually begin with the oath of one of the complainers. If the warrant following on the complaint requires to be executed in a county different from the one in which it was granted, the concurrence of a justice of peace of such other county is necessary. A workman deserting from England and going to Scotland, or deserting from Scotland and going to England, may be apprehended on a warrant granted in the county from which he deserted, provided it be indorsed by a justice of the county to which he has absconded. When he is apprehended, the subsequent proceedings must be in strict conformity with the statute, otherwise they will be quashed. When followed by conviction, the workman is subjected to the punishment authorized by the statute; but Lord Ellenborough observed, that "it would be clearly against the policy of the law, if the servant, by his own act of delinquency, should have the power of dissolving the contract," merely because he has undergone punishment inflicted for the breach of it; and, therefore, after being punished, he is bound to return to his service and complete his engagement to his master.

By the statute 1st and 2d Will. IV., cap. 37, it is provided that the wages of certain workmen (of whom a very comprehensive description is given) shall be paid in the current coin of the realm, or notes of the Bank of England, or other bankers entitled to issue notes, or in drafts or orders payable to the bearer on demand, within fifteen miles of the place; otherwise the contracts cannot be enforced by the master. This provision applies to servants connected with the getting of coal, lime, stone, slate, clay, bricks, or salt; or engaged in the manufacture of iron or steel, or of articles of hardware, or plated articles, cutlery, or goods made of brass or other metal, or japanned goods, and almost all kinds of cloth, silks, and lace; leather, glass, and earthenware. The object of the statute is to prevent the frauds which were too often practised on workmen, by masters keeping provision stores, and selling articles of bad quality at a high price, in payment of wages. There is nothing to hinder the wages of such servants as do not fall under the classes specified in the statute, from being paid in any way that may be arranged; but any attempt to control the mode in which any workman may spend his wages is illegal. If, in face of the last-mentioned statute, even although the consent of the workman be obtained, the master retain the price of goods out of the wages, and the workman, or his wife, widow, or child in minority, should within three months after become chargeable to the parish, such parish is entitled to compel the master to pay over again the wages so retained. There are various exceptions to this rule, intended for the advantage of the workman, such as the cost of medicines or medical attendance, tools for mining, hay or corn to be consumed by any beast of burden employed in his trade by the workman, the rent of his house, or of victuals dressed and consumed under his own roof, or money advanced to a friendly society or savings-bank to relieve him in sickness, or to educate his children. Where advances of that kind are made by the master, they may, notwithstanding the statute, be deducted from the wages, provided they are made under a written agreement to that effect. Masters contravening the statutory regulations may be punished by a fine not exceeding L.10, nor under L.5 for a first offence; not exceeding L.20, nor under L.10, for a second offence; and not exceeding L.100, at the discretion of the court, for a third offence;—ten days intervening between each offence, otherwise each separate offence is held as a first. Every succeeding offence beyond the third is treated as a third offence; and the right to prosecute is not held to be abandoned until the lapse of two years. The different classes of workmen last above alluded to may, on complaint to a justice of the peace, be discharged of their contract with their masters on proof of ill treatment, refusal of stipulated provisions or wages, cruelty or other ill usage.

Attempts have been made to prevent or abridge litigation between masters and workmen. By the 5th Geo. IV., cap. 96, provision is made for settling some particular disputes by arbitration; and improvements on that statute have been made by 7th Will. IV., 1st Vict., cap. 67, and 8th and 9th Vict., cap. 77. It would altogether exceed the bounds allotted to this article to attempt to specify the kinds of dispute which may be so disposed of, or to explain the proceedings which must be adopted. It is safer to refer to the statutes themselves, only observing, generally, that on either master or workman going before a justice of the peace, the justice has power to settle the dispute in a summary manner, provided both parties agree in writing to abide by his determination. If they decline, then the justice may propose four or six persons, one-half being masters, agents, or foremen, and the other half being workmen, out of whom the master may select one, and the workman another, to act as arbiters, whose determination is final. If they differ in opinion, the justice may then act as umpire. If both parties agree to a different mode of adjustment, the law gives effect to their agreement. We are not aware that these provisions have been acted on so frequently as they should; on the contrary, we fear that combination is, unhappily, too often resorted to rather than arbitration.

3. *Of Combinations.*—This leads us to notice the improvement, in favour of workmen, which was effected by the statute 6th Geo. IV., cap. 129. Previous to that statute the most peaceable combination on their part to raise their wages was an indictable offence. For this there was no sound reason whatever, provided all acts of violence were avoided. That statute, therefore, made it lawful, alike to masters and workmen, to combine for the purpose of regulating wages and all the other conditions of labour. Since then, combinations have been somewhat frequent in Great Britain. On the part of workmen, their principal objects have been to fix a minimum rate of wages, to diminish the hours of labour, to decrease the quantity of work, to prevent masters taking more than a specific number of apprentices according to the number of journeymen employed by them, and to support each other during their refusal to work, in the hope of forcing their masters to comply with their terms. Of course, the object of the combinations on the part of masters is to counteract those of the workmen, and to secure terms more favourable to themselves. While these objects are sought to be attained by discussion and appeals to reason, with merely refusal in the absence of contracts to work, the law will not now interfere; and in the long run the disputes are generally equitably adjusted, though more frequently to the disappointment and loss of the workmen, who are often defeated by means of the capital of their employers, and the facilities with which other workmen can be procured from a distance. The loss and misery which workmen and their families have endured during these struggles, though the masters have not come out of them uninjured, would form an instructive chapter. So long, however, as parties not under contract conduct themselves peaceably, the law leaves them to combine for the regulation of their contracts, and to assist each other with pecuniary aid as they best can; but the instant that violence or intimidation is resorted to, an offence is committed which is justly punishable with great severity. To threaten a master or any one with violence is punishable at common law. To molest or intimidate a workman, to compel him to join an association, or to prevent him from hiring himself on such terms as he may please, is punishable by the statute with imprisonment for a period not exceeding three months, with or without hard labour. Of course there are many ways in which a workman may be intimidated without violence being committed, or threats uttered; and therefore the law will interfere wherever such is plainly the object of acts which in themselves may be harmless. The assemblage, for example, of numbers of persons acting in combination, whose appearance and gestures may reasonably alarm men willing to work, is in certain circumstances punishable, even though no direct act of outrage be committed. The question is, What is the purpose and object of the parties? Do they intend to create fear, and thereby force a man of ordinary resolution to abstain from working? If it be plain to a jury or to a magistrate that the object of the assemblage is to overawe, the offence is held to be committed; and such assemblages may be summarily dispersed by a magistrate. Where, however, the magistrate is not satisfied of the existence of the guilty intention, or believes that the parties have assembled only for the purpose of discussing their own grievances, he will, of course, decline to interfere; though he will not readily believe that they would choose the vicinity of factories, or the roads to and from workmen's houses, as suitable places for such discussions. The procedure under the statute is summary. It enacts,—"That if any person shall, by violence to the person or property, or by threats or intimidation, or by molesting or in any way obstructing" workmen, force, or endeavour to force them to quit their work, or to refrain from hiring themselves, or to cause them to join the combination or contribute to any common fund, or force any master to make any alteration in his mode of carrying on his business, or to limit the number of his servants,—parties so offending shall, on complaint within six months, be brought before any two justices of the peace, who, after finding the charge proved by the oath of one or more credible witnesses, shall adjudge the offenders to be imprisoned, with or without hard labour, for any period not exceeding three months. But it is to be observed, that this statute does not by any means take away the cognisance which the common law takes of such offences, or hinder them from being stated as aggravations of an ordinary assault in a higher court; so that if the grounds of complaint be considered too serious for the adjudication of justices, proceedings may be adopted before the ordinary criminal courts, in which sentences have been pronounced varying from six to eighteen months' imprisonment, and from four to fourteen years' transportation, according to the nature of the violence proved.

4. *Servants in Factories.*—The following statutes have been passed for the relief of women and children employed in factories, viz.,—42d Geo. III., cap. 73; 3d and 4th Will. IV., cap. 103; and 7th Vict., cap. 15. A great variety of objects are sought to be attained by these statutes; among others, the prevention of oppression by excessive work; the limiting of the hours of juvenile labour, and hindering night work; the education of children, securing to them suitable dormitories, ventilation, meals, clothing, holidays, and precautions against accidents. We cannot enter into details. The statutes apply to all cotton, woollen, and other factories wherein steam or water, or any mechanical power, is used to work the machinery; and wherein three or more apprentices, or twenty or more other persons, are at any time employed. No child under eight years of age can be employed in such factories, nor until thirteen years of age can any child be kept at work in them for more than six hours and thirty minutes, or, in some cases, seven hours, a day. In certain events such children may be employed ten hours on each of three alternate days, so that their labour throughout the week is not increased. The certificate of a surgeon as to the fit-

ness of such children for the work is required. Between the age of thirteen and eighteen years, young people may be employed twelve hours a day, but not more than sixty-nine hours in any one week, nor during the night between half-past eight o'clock in the evening and half-past five in the morning; and no person under eighteen years of age can be employed after half-past four on the Saturday afternoon. Females above eighteen years of age cannot be employed longer or otherwise than persons between the ages of thirteen and eighteen. Holidays are secured to the extent of eight half-days annually. The statutes do not apply to persons employed in repairing machinery or packing goods; but they prohibit the employment of children to clean machinery while it is in motion. To enforce these regulations government inspectors are appointed; and masters, under penalties, must keep a register of a great variety of particulars, open to the examination of the inspectors. They must also fence their machinery to the satisfaction of the inspectors, unless, on a reference to arbiters, it be ascertained either that it is sufficiently, or that it cannot be better fenced.

5. *Servants in Printworks.*—Regulations are enacted in reference to them by the 8th and 9th Vict., cap. 29, very similar to those applicable to the class last above referred to.

6. *Miners and Colliers.*—By the 15th Geo. III., cap. 28, and 39th Geo. III., cap. 56, these labourers, who previously were literally in a state of bondage, were placed on the same footing with other servants. The 5th and 6th Vict., cap. 99, was passed chiefly to prevent masters from employing boys under ten years of age, and females, in mines; and to render it illegal to enter into indentures with boys for more than eight years, or to intrust any person, except males above fifteen years of age, with the charge of steam-engines by means of which persons are passed up or down a shaft, pit, or inclined plane. It is also unlawful to pay the wages of miners in a public-house; otherwise payment may again be enforced. In all these instances penalties are incurred for any violation of the regulations; and government inspectors are appointed to secure that the regulations are enforced.

7. *Chimney-Sweepers.*—The 3d and 4th Vict., cap. 85, enacts that no person shall be bound apprentice to a chimney-sweeper under sixteen years of age, or be compelled to go up or down a chimney under twenty-one, either for cleaning it or extinguishing a fire, under penalties.

8. *Seamen and Sea Apprentices.*—The statutory provisions on behalf of these classes of servants are too numerous to permit us, within our limits, to give any specification of them. We must therefore refer such of our readers as require information about them to "An Act to amend and consolidate the Acts relating to Merchant Shipping," 17th and 18th Vict., cap. 104, amended by 18th and 19th Vict., cap. 91. We have also to refer to 17th and 18th Vict., cap. 120, for an enumeration of all the prior acts and parts of acts relating to merchant shipping which are repealed or continued. We may state generally that all merchant vessels (not pleasure yachts) of 80 and under 200 tons burdens, must have one apprentice; 200 and under 400 tons, two apprentices; 400 and under 500 tons, three apprentices; 500 and under 700 tons, four apprentices; and 700 tons and upwards, five apprentices at least, who must be above twelve and under seventeen years of age, bound for four years at least, subjects of Her Majesty. They may be employed in any ship during the currency of the indentures of which their master is owner or master. The statutes define with great minuteness the nature and form of their agreements, and enact summary modes for compelling them to join and to remain with the ship, and for the regulation of their conduct at sea. They also make anxious provision for their good treatment by their masters both at home and abroad, and for enforcing all their just claims against their masters.

9. *Domestic Servants.*—They differ from all other servants chiefly in these respects,—that they are not entitled to absent themselves from their master's family, except in cases of extreme necessity, without leave; they must avoid all nice distinctions about their work; give ready obedience, "not answering again." They have no fixed hours of labour, but must work if required, in so far as is consistent with their health and strength. Any act of indecency or dishonesty justifies immediate dismissal, as does a repetition of an instance of intoxication. Bad health relieves them from their duties while it lasts, and when it is not imputable to gross misconduct, their wages are not diminished, unless it become very protracted. The precise length of time is not invariably fixed. In ordinary cases in Scotland, where the hiring is generally for six months, six weeks must be submitted to. In one case, where the engagement was for a year, a fifth part of that time, under special circumstances, was allowed. The domestic servant is not bound to make up the time lost by sickness. The law of England does not authorize the master to turn away the servant on account of sickness; but if he go away without leave, the contract is dissolved. If the sickness be the result of debauchery, or if the servant concealed bad health existing at the time of hiring, or if he have contracted debt and be imprisoned for payment, his master may put an end to the engagement. The endurance of the engagement depends on special agreement, or is regulated by custom. It is usually, in England, terminable on a month's notice; and in Scotland it lasts for six months, terminable on a warning of forty days; and after such warning is given, the servant is entitled at suitable times to go in quest of another situation. Till the warning be given by either party wishing to bring the engagement to a close, it is held to be tacitly renewed. During its currency or renewal the domestic servant cannot maintain residence in the master's house against his will, but must remove on being required. If, however, the removal be enforced on insufficient grounds, the servant is entitled to wages and board-wages, and even damages, if accompanied by cruelty, such as turning a friendless female out of doors at an unseasonable hour. The marriage of a servant of either sex, or the enlistment of a man-servant, is not a misdemeanour; so that if they can arrange to complete their term of service, the master must perform his part of it; but by the Mutiny Act the enlistment interrupts the service, and entitles a justice of the peace to award to the servant a proportion of his wages. In England it rather appears that a woman marrying during the period of her service cannot be withdrawn from it by her husband until its termination. In Scotland the husband may withdraw her, but he is liable to her master in compensation for the loss of her services. If a domestic servant die before the termination of the engagement, the executors can only claim wages for the period actually served. If the master die, the claim of the servant is exactly what it would have been in the case of unwarrantable dismissal, with this qualification, that the master's executors liable in such a claim are entitled to have the service till its legal termination. Sometimes the amount of wages has not been fixed by the parties, as, for example, where a destitute young person is taken into a family, and works, with little advantage at first to the family, till at length the services become useful, nothing having been said about wages; and then the question has arisen, whether in such circumstances wages are really due. Both in England and Scotland it has been decided, that where service is given, wages must be paid. In such cases the amount is fixed judicially, on a consideration of the whole circumstances. Loss by accidental breakage by a servant cannot legally be deducted from the wages, unless it evidently arose from gross carelessness. Servants have no preferable claim for wages on the bankruptcy of

their master, as farm servants have; but if his death occur during the currency of the engagement, they are generally ranked on his estate after the undertaker and landlord.

10. *The higher order of Servants than those above alluded to, such as Governesses, Tutors, Clerks, Managers, of Establishments, and Editors.*—It can scarcely be said that any practice or usage with reference to them has been so uniform and long-continued as to constitute a rule. Some of those hirings, such as of managers and editors, are so important that they are probably always made the subject of special bargain. Where such contracts are during pleasure, they may be terminated without any cause being assigned. Whenever it appears from the circumstances, that the parties had undoubtedly some considerable period in view, a year at least will be presumed. In a Scotch case, where a course of tuition by a tutor was evidently contemplated, and in an English case, where a warehouseman was to receive wages at the rate of so much monthly, with a progressive rise till they reached a given sum per annum, engagements for a year were presumed. Clerks would rather appear in Scotland to be hired during pleasure, and in England they are understood to be hired for a year. In a case before the English courts relative to clerks it was remarked,—"We must decide this case according to the general rule, and hold the contract between the parties to be a hiring for a year."

In conclusion, we may remark (1), That a practice existed in Scotland by which masters obtained summary warrants to apprehend servants who deserted during the currency of their engagement, and imprison them until they found security to return to their service; and that practice was justified by a judgment of the Court of Session pronounced so recently as 1824. That judgment, however, was pronounced after a very imperfect discussion, and its soundness has been much questioned. The origin of the practice must be sought for at a time when servants were not regarded as being equally the objects of the protection of law with their masters, and when they were probably under the arbitrary regulation of the magistrates, than which nothing can be more objectionable. There is nothing in the contract between master and servant unlike other civil contracts. On either side a failure to fulfil the contract gives rise to a claim of reparation, which ought to be recovered like other civil claims; and the very fact that it has been thought right, by special statutes, to enforce the obedience of some classes of servants, seems to imply that, in the absence of such statutes, a contract of service with others should only be enforced by the ordinary forms of law.

2. None of these statutes can be stretched beyond their clear enactments, nor extended to classes to which they do not expressly apply, as they can only be justified by the peculiar necessities of particular trades.

3. The history of combinations proves that, whether on the part of masters or workmen, they are useless and mischievous. On the part of skilled workmen their objects, in addition to those above referred to, are sometimes to require that masters shall hire no workmen unless they be members of their union, and that in the order in which their names are engrossed in the union-books, nor at less than their fixed rate of wages; otherwise all combined workmen strike work. Sometimes it happens that these demands are so excessive, that masters are forced to combine in turn, and stop their works, until the unionists reduce their demands, or can be replaced by servants from a distance, thereby involving thousands of workmen and their families in destitution. The attempt of the workmen to sustain themselves, during the *strikes*, out of a common fund has generally failed—the money gathered being insufficient. The tendency of combination is injurious to the workmen, because it destroys all inducements to industry among them; seeing that if masters are only to hire workmen in the order of their enrolment, and all at fixed rates, the inferior and idle are placed on a level with the industrious and skilful. Such a system, which will always be popular with inefficient workmen, operates just as would be the case if all physicians and lawyers were employed by rotation and at the same fees, which would no doubt be relished by the men of inferior talents in both professions, but would paralyze the exertions of the most eminent. This is quite obvious; and yet workmen who disapprove of unions are often compelled to join them, because, unless they do so, the other workmen would not remain in the service of their master. In the end great injury is inflicted on both parties, though generally most heavily on the workmen. In 1834 the west of Scotland was convulsed by a strike among calico printers which lasted nine months. Intimidation, which was resorted to, was counteracted by the military, and was followed by merited punishment. In one establishment business was suspended, and two thousand workmen, with their families, were thrown into destitution. At length that establishment, after an adjustment with its creditors, resumed business with new hands procured from a distance at reasonable wages, while the unionists were scattered in starvation over the country. This was not a rare example. While, therefore, skilled workmen are permitted to try every lawful means to better their condition, their success depends mainly on their rendering it, by good conduct, the interest of their masters to employ them. The competition which must ever exist among masters will always induce them to give the highest wages they can afford, to secure the best workmen; and any attempts to force wages above that point must force the attention of masters to improvements in machinery, and the training of unskilled labourers to supersede the refractory. The regulation of labour and wages depends on principles which can only be affected by combinations for a very limited period; while nothing workmen can do, will permanently check the pressure of their own numbers on the means of employment. Wherever labour is abundant it will be cheap; and when workmen resort to intimidation they engage in a most unequal conflict with the law; while skill and attention, according as they are in demand, will generally find their place in the market. (M. L.)

MASTIC, or MASTICH, the μαστίχη of the ancient Greeks, is a concrete resinous exudation from the trunk and branches of the *Pistacia lentiscus* (Nat. Ord. *Anacardiaceæ*), a bush about 12 feet high, growing on the coasts and islands of the Mediterranean, and particularly the island of Chios, where it is very abundant, and is extensively cultivated for its resin. Mastic is produced either by spontaneous exudation or by transverse incisions made in the bark in the month of August, when the resin exudes in tears, and either hardens upon the tree or falls to the ground. In the former case it is of a superior quality, and is called picked mastic, consisting of roundish, elongated, or flattened tears, varying in size between a pepper-corn and a hazel-nut, of a pale yellow colour, and translucent, brittle, and glassy in fracture, and possessing a slight but agreeable balsamic odour and taste. This kind of mastic is sometimes adulterated with sandarach. The coarser kind, called mastic in sorts, is of a greyish-brown or black colour, and is rendered impure by the presence of fragments of wood, bark, and sand, collected by the resin in falling to the ground.

Mastic, besides containing traces of volatile oil, produces by dissolution in boiling rectified spirit a white ductile substance, which some have regarded as a peculiar principle under the name of Masticin. Mastic is much used by the Turkish ladies for consolidating the gums, cleaning the teeth, and sweetening the breath. When chewed it becomes ductile, grey, and opaque. It is also employed occasionally for stuffing decayed teeth. It is chiefly used in this country for compounding varnishes, and is imported from the Grecian Archipelago packed in chests.

MASULIPATAM, a considerable town and seaport of Hindustan, in the Northern Circars, and the principal place of the district of the same name. It is defended by a fort, which is of a rectangular figure, 800 yards in length by 600 in breadth, and situated in the midst of a salt morass, close to an inlet or canal, which communicates with the sea and the Krishna, so that the adjoining grounds may be inundated at pleasure; and this constitutes its principal defence. The port is not capable of receiving vessels beyond the burden of 300 tons, the shore being flat and the water shallow; ships are consequently compelled to anchor at some distance from land. The town is situated on a piece of ground rising above the fort, a mile and a half to the N.W., and communicates with it by a straight causeway 2000 yards in length. Many of the houses are large, and well built of brick and lime mortar, with upper storeys and tiled roofs, and most of the dwellings of the poor are commodious and clean, in consequence of the neatness indispensably required for the manufacture of cotton chintzes, for which the place has been long famous. The population of the town has been returned at 27,884; Lat. 16. 10., Long. 81. 13. The district, of which this town is the chief place, has an area of 5000 square miles, with a population amounting to 544,672. It forms one of the Circars which were obtained by the French in 1753, and remained in their possession till 1759, when Clive transferred them to the East India Company, to whom they were formally ceded in 1765 by the Emperor of Delhi.

MATAMORAS, or MATAMOROS, a town and port of Mexico, department of Tamaulipas, situated on the right bank of the Rio Grande, about 40 miles from its mouth. The town is well built, and is the seat of a considerable trade. The principal articles of export are specie, horses, wool, and hides; and the imports consist of manufactured goods from Great Britain and the United States. The town has but recently grown to its present importance, from a small village. Pop. about 10,000.

MATAN, a small island of the Philippines, near the E. coast of Zebu; Lat. 10. 16. N., Long. 123. 48. E. It is about 10 miles in circumference, and is only noted as the place where the navigator Magalhaens was killed in a skirmish with the natives in 1521.

MATANZAS, a seaport of Cuba, on the N. coast of the island, at the head of a deep bay, 57 miles E. of Havaña; Lat. 23. 2. N., Long. 81. 38. W. The town is well built, about a third of the houses being stone, but without much pretension to architectural beauty. The principal buildings are two churches, an hospital, barracks, theatre, and public library. The harbour is protected by a natural breakwater, consisting of a ledge of rock 4 feet below the surface, through which entrance is afforded by two channels, one to the N. and the other to the S.; but the former only is passable for large ships. The harbour has also been much reduced in size and depth by the mud carried down by two rivers, one of which flows on each side of the town. The number of vessels that entered the harbour in 1851 was 499; that cleared, 578. In the same year the exports amounted in value to L.393,641, and the exports to L.1,119,453; while the duties collected on imports were L.118,372, and on exports L.63,561. The surrounding country is one of the richest districts of Cuba; and the bay is large and convenient for ships, being sheltered from every wind but the N.E. Previous to 1809, owing to the restrictions put upon its trade, Matanzas was a place of small importance; but in that year these were removed, and the result has been an increase, not only in the commerce of the town, but in the raising of sugar, coffee, and other articles in the neighbourhood. The principal articles of export are sugar, molasses, and coffee. Pop. (1854) 26,000.

MATARO, a seaport of Spain, on the Mediterranean, in the province and 21 miles N.E. of Barcelona; N. Lat. 41. 32. 5., and E. Long. 2. 28. 24. The town is beautifully situated, partly on the slopes of the Cordillera which separates the coast from the Vallés, and partly on the plain beneath. Hills, covered to the summits with vines, shelter it in the form of an amphitheatre from the cold northern winds. The streets of the new town, the part of the city next the sea, are handsome and regular. The most notable buildings are the church of Santa Maria, dating from 1675, which contains some good pictures; the hospital; and the theatre. There are schools of navigation and of the fine arts; but the chief educational institution is the college of PP. Escolapios, founded in 1737, and in 1829 incorporated with the university of Cervera. Close to the walls flows the small River Cirera. The principal agricultural product is wine, which is exported by Barcelona. There is a considerable fishery, the results of which are disposed of inland, in Manresa and other places. The railway connecting this town with Barcelona, which was opened in October 1848 (the first in Spain) has given a great impulse to the industry of Mataro. It is entirely a manufacturing town. There are ten cotton factories, of which seven are worked by steam; also of cotton and woollen cloth, silk, velvet, and stockings. The manufacture of canvas and of tarpaulin is extensively carried on, and several hundred women are employed in making lace. There are numerous potteries and various chemical works; leather, glue, glass, bricks, and some other articles are also made. The trade is carried on chiefly through Barcelona, Mataro having no artificial harbour, and the attempts at various times to construct one having been frustrated. The modern name of the town, Mataro (μάραθρον?), appears, according to some, to correspond with the ancient Latin name *Civitas Fœnicularia.* Mataro enjoyed many privileges from the Spanish monarchs in reward for its generous assistance in their naval expeditions. The most melancholy page of its history is the cruel sack it underwent from the French on the 17th of June 1808. The celebrated Capmany, author of the *Teatro Historico-critico de la Elocuencia Castellana*, and other excellent works, was a native of this town. Pop. (1845) 13,010.

MATCHES. Previous to the invention of the common lucifer match, the contrivances for procuring light, while frequently ingenious, were generally attended by some serious inconvenience. The plan adopted by savage nations is the laborious one of igniting by friction two pieces of dry wood. A readier method, but still a clumsy contrivance, was the flint and steel and tinder-box, in common use among ourselves till about thirty years ago. Attempts were made to supersede the tinder-box by such expensive and complicated contrivances as the *pyrophorus*, the *pneumatic tinder-box* or *light syringe*, the *hydrogen-lamp* of Dobereiner, &c.; yet the present simple and convenient lucifer is rather an improvement on the sulphur match than a modification of any of those more complex arrangements. One of the first forms of improved match was based on the fact that chlorate of potash, mixed with suitable ingredients, is decomposed by sulphuric acid, with the production of fire; the sulphur match was accordingly tipped with a paste composed of 30 parts chlorate of potash, 25 parts sulphur, 2 parts colophony, 1½ vermilion, and 2 of gum in solution; and the match thus prepared was dipped into a bottle containing asbestos moistened with sulphuric acid, and rapidly withdrawn, when an explosive flame was generated which set fire to the wood. These matches, although inconvenient, soon became common, and were sold at 1s. per box under the name of *Eupyrion.*

The next form of the chemical match obtained the name of *Prometheans.* In this contrivance the paste consisted of equal parts chlorate of potash and sugar, mixed with a solution of gum. The sulphuric acid was ingeniously contained in a small glass bead, which, with a small quantity of the paste, was rolled up in gummed paper. On pinching the extremity of the roll with a pair of pliers, the bead was crushed, and the acid coming into contact with the chlorate, produced a burst of flame.

The next improvement was the *friction-match*, which appeared about the year 1832. In this contrivance the sulphur match was tipped with a composition consisting of 1 part chlorate of potash and 2 parts sulphuret of antimony, mixed with gum water. This match was ignited by drawing it briskly through the folds of a piece of sand-paper held between the finger and thumb.

The chief improvement in the match was the introduction of phosphorus into the composition of the paste, with which many ingredients were tried, such as magnesia, lime, sulphur, white-wax, cork-powder, &c., while chlorate of potash continued to be used; and as this material produced on ignition a noisy crackling sound, resembling Congreve rockets, the name of *congreves* was applied to the matches. When this explosive noise was got rid of, matches were called *noiseless lucifers*, and subsequently *lucifers*, a word which has found a permanent place in our language.

The manufacture of lucifer matches is at the present time of vast extent and importance; a single manufacturer exporting from London alone not less than 8000 cwt. of matches every year. The first operation at one of these factories is the sawing up of the timber into blocks, each 30 inches in length, 4½ in width, and 3 inches in thickness, by means of a circular saw, cutting across the fibres, so that each plank furnishes about 30 blocks. From these blocks *splints* for the matches are cut by means of a machine, patented by Reuben Partridge in 1842. Each block is placed endwise in a frame furnished with a crank bearing a horizontal arm, at the end of which is a block containing from thirty to forty lancet-points, separated by pieces of brass of the thickness of the intended match. The motion of the crank brings the lancet-points under the end of the block, and the points cut or score the wood to the required depth for forty splints. As the lancet-points are withdrawn by the revolution of the crank, a knife is made to swing round horizontally, and mow off a layer from the end of the block thus scored, containing forty splints each, two matches in length. The knife is then withdrawn, the lancet-points again advance, and the process is repeated as before. The splints fall into a room below, where they are made up into bundles of 1000 each, and afterwards dried in rooms heated to the temperature of 300°. When the bundles are taken out, both ends are dipped into melted sulphur, a kind of twist being given to each bundle to prevent the splints from being glued together by the sulphur. The bundles are now divided, each into two halves, by means of a circular saw, and are ready for tipping with the phosphorus paste, after which they are packed into boxes. The composition of this paste varies with different manufacturers; but the principle of its action is the same in all common matches, viz., an emulsion of phosphorus is made with glue or gum, and this being applied to the end of the sulphured matches, they are exposed in a warm room until a sufficient quantity of the phosphorus has been driven off by slow combustion, so as to leave a sheet of glue or gum, which protects the remaining phosphorus from the oxidizing influence of the air. When the end of the match is drawn briskly across sand-paper, a portion of this gelatinous envelope is removed, while the heat occasioned by the friction ignites the phosphorus, and sets fire to the sulphur. The composition contains, among other ingredients, sand for promoting the friction, and colouring matter—such as red ochre, smalt, or artificial ultramarine. Matches of this kind ignite with great facility without any noise, and are therefore dangerous; while the large proportion of phosphorus which they contain renders them highly poisonous. Increased hardness, and consequently greater safety, is given by the use of chlorate of potash; but this makes a noisy match, and produces a white bursting flame. In some cases nitre is used instead of chlorate of potash, the oxygen of both the salts assisting the combustion of the phosphorus. Some of the matches made in Germany for use in climates less moist than that of England, are tipped with a composition of gum, nitrate of lead, or peroxide of lead and phosphorus. In well-compounded preparations the proportion of phosphorus may be very small, not more than from 5 to 10 per cent. Some use the following compound:—Phosphorus, 1 part; nitre, 10 parts; fine glue, 6 parts; smalt, 2 parts.

The great objection to all ordinary pastes is the use of common phosphorus, which fills the air of the factory with fumes of phosphoric acid, whereby the health of the workpeople is greatly affected, and in many cases necrosis of the lower jaw produced. The only complete preventive consists in the employment of the *red* or *amorphous phosphorus*, discovered by Schrötter a few years ago, and which is not volatile. It is said that Herr Lundström, of Jönköping has successfully employed the red phosphorus lately in the following manner:—The matches are tipped as usual with sulphur, stearine, spermaceti, or wax, and then with a composition consisting of 6 parts chlorate of potash, from 2 to 3 of sulphuret of antimony, and 1 part of glue; while, instead of the usual sand-paper on the match-box, the sides of the box are covered with a friction paste consisting of 10 parts of red phosphorus, 8 parts oxide of manganese or sulphuret of antimony, and from 3 to 6 parts of glue. This ingenious arrangement is said to be perfectly successful, and if so, it deserves the name of *safety-match*, which has been proposed for it, since this kind of match cannot take fire by accidental friction, while such matches are not poisonous, as is the case with common lucifers.

The *vesta*, or taper-match, consists of a wick of untwisted cotton, covered with wax, and tipped with an inflammable paste containing a large proportion of chlorate of potash. In preparing these matches, from 100 to 200 lengths of wick, kept separate by means of combs, are made to pass through a bath of melted wax, and then through holes in a metal plate, which draws them to the proper size and shape. They are next cut into lengths for the vestas by a machine-moved knife, and being arranged on frames, are tipped with the composition. *Fusees* for lighting cigars are prepared from strips of cardboard, steeped in a solution of nitre, and cut nearly through into the required number of lights.

The manufacture of lucifers is spread over a considerable part of the world, and forms a vast and increasing trade. It is said that in this country at least 40,000,000 matches are made *per diem*, while large quantities are imported from Germany and other parts. In this country, where the extent of the manufacture is much less than in Germany, upwards of 8 tons of phosphorus, and 26 tons of chlorate of potash, are consumed every year for tipping matches. The cheap rate at which lucifer matches are manufactured is remarkable. It is said a German manufacturer will sell a case of 50 boxes, with 100 matches in each box, for 4d. (C. T.)

MATCHIN, a town of European Turkey, in Bulgaria, situated on the right bank of the Danube, 32 miles N.E. of Hirsova. It is defended by two forts; and was the scene of a victory gained by the Turks over the Russians on 24th December 1853.

MATELICA, a town of Italy, in the States of the Church, situated on the River San Angelo, a tributary of the Esina, 23 miles W.S.W. of Macerata. It is an old town, surrounded by walls, and contains several churches and convents. The inhabitants are chiefly occupied in the cultivation of the neighbouring country, and in the manufacture of coarse woollen stuffs. Pop. 7270.

MATERA, a town of Naples, capital of the province of Basilicata, is situated in a deep valley on the right bank of the Gravina, a tributary of the Bradano, 128 miles E. by S. of Naples, and 44 E. from Potenza. The town, which is defended by walls, is generally well built; and contains a cathedral and archiepiscopal palace, which have porticos consisting of granite Corinthian columns, supposed to be the remains of an ancient temple. Not far from the walls stands an old tower known by the name of Torre Metella; and there are also in the town six convents and a college. The neighbouring country is rich in pastures; and the valley is surrounded by hills, which contain many curious caverns. Pop. 12,000.

MATERIA MEDICA. The signification given to this term by different authors has varied very much indeed, some employing it to denote the whole range, and others only a particular department, of that branch of medical science which relates to the means employed for the prevention or in the treatment of diseases. Prophylactic or preventive, and remedial or curative means, may be referred to three principal divisions: 1st, The performance of manual operations; 2d, The regulation of what have been termed the non-naturals, as of diet, exercise, temperature, clothing, &c.; and, 3d, The employment of medicinal substances. Manual operations, as far as their mode of performance is concerned, fall under the domain of surgery; the regulation of the non-naturals is the object of dietetics and hygiene. As to the third division (medicinal substances), they may be considered either in reference to the sources from which they are derived, or to the modes in which they are prepared for medical use; or they may be considered, along with the other two classes of means, in reference to the immediate purposes for which they are employed in the treatment of diseases, and the *indications* which they are intended to fulfil. Now, the term materia medica has by some been understood as embracing the consideration of remedies in all these respects. But by others, and, as we conceive, more correctly, it has been limited to signify the natural and commercial history of medicinal substances. Those processes by which medicinal substances are fitted for use constitute the department of pharmacy, whilst the purposes for which remedies are employed form the objects of consideration in therapeutics. Some have employed the word pharmacology as a general term, to include the whole of the knowledge that has been obtained relative to remedies.

MATERIALISM is the name given to that speculative theory which resolves all existence into a modification of matter. (See METAPHYSICS.)

MATHEMATICS (μάθησις or μάθημα) properly signifies the discipline of the mind acquired in studying a science, rather than its subject matter; and is a term descriptive of any species of knowledge which tends to improve the mental faculties. It is employed, however, in a restricted sense, to denote the science whose object is the discovery of the abstract relations of number and magnitude, and their application, by means of observed laws, to the explanation of natural phenomena, and the improvement of the useful arts.

Although in every department of mathematics results are obtained by strictly logical deduction from a few first principles explicitly assumed, yet the science may be regarded as consisting of two distinct branches, according to the nature of the evidence on which the truth of its first principles is admitted. In the one, which constitutes *pure mathematics*, the first principles require no special inductive process to convince us of their truth, and scarcely, indeed, demand the evidence of our senses. Whether they are notions inherent in the mind, or deductions from our constant and earliest experience, they are universally allowed to be self-evident, in the sense that we cannot conceive them to have been otherwise than they are. Thus pure mathematics is founded upon definitions of necessary truth, and is pre-eminently the most certain of all the sciences.

Mixed mathematics denotes the application of *pure* mathematics to natural objects; and presupposes some knowledge of their properties derived from the senses, or of general laws obtained by induction from a sufficient number of observations. The logical, or strictly mathematical processes of deduction in the pure and mixed mathematics are identical; the difference between the two sciences being, that in the one, the first principles are self-evident, while in the other, laws and facts, which are not necessarily self-evident, but derived from observation, are admitted, along with the axioms and definitions of pure mathematics, as fundamental principles of the science. Again, in mixed mathematics we are often presented with conclusions derived from hypotheses regarding the constitution of nature. If we ask whether these are correct conclusions from the assumed hypotheses, our investigations must be conducted on principles purely mathematical: but if we inquire whether the conclusions have a real existence in nature, we must appeal to observation; and our reasoning becomes inductive. It is from this mixture of mathematical deduction with experimental processes that the mixed sciences derive their name, and not from any difference between their mathematics and those of pure science.

Thus the evidence for the conclusions of mixed mathematical science is inferior to that obtained in pure mathematics, only in so far as the utmost confidence in the truth of laws arising from even the highest degree of probability attained by inductive reasoning, must always fall short of the conviction which follows from the perception of necessary truth. If, however, we estimate the rank of a science by the perfection of its methods,—the power it confers of pursuing the most lengthened and complex processes of reasoning with perfect certainty of the correctness of the results—its consequently perpetually extending and cumulative character—the almost hopeless difficulty of the problems it has solved—the remoteness of the conclusions to which it has conducted the inquirer into natural laws—the number and importance of the truths with which it has enriched mankind—or, in short, the almost incredible degree in which it has aided and amplified the reasoning faculties,—we must accord both to pure and mixed mathematics the first place among the various departments of human knowledge.

The different branches of mathematical science may be classified as follows:—

I. Pure mathematics consists of the following branches:—

1. *Arithmetic*, which may be subdivided into *pure arithmetic*, or the ordinary science of numbers, and of numerical calculations conducted by means of the common arithmetical notation; and *algebra*, or the methods of calculation by means of general symbols, so far as the processes are restricted to actual numerical operations. (See ARITHMETIC.)

2. *Geometry*, which investigates the properties of figures in the manner of Euclid's *Elements*, without the aid of algebraical processes. (See GEOMETRY, and CONIC SECTIONS.)

3. *Algebra*, or the calculus of operations, differing from arithmetical algebra in the more extended definition of its operations, and their more universal applications. (See ALGEBRA.)

4. The application of algebra to geometry, including coordinate geometry. (See ANALYTICAL GEOMETRY.)

5. The differential and integral calculus, which include the general theory of limits, or those methods of operation in which the limits of ratios are employed in calculation, and denoted by specific algebraical symbols. (See FLUXIONS.)

II. Mixed mathematics includes the application of pure mathematics to mechanics, astronomy, optics, heat, electricity, &c. (See ASTRONOMY, &c.) The theory of probabilities is usually included under this head, although it has perhaps equal claims to rank under pure mathematics.

(For the history of mathematical science the reader is referred to the articles ALGEBRA and GEOMETRY, and to the *Preliminary Dissertations.*) (W. S—N.)

MATHER, COTTON, D.D., a learned American divine, the son of Increase Mather, was born at Boston in February 1663. He received his elementary education under his father's care, and at the age of twelve he entered Harvard College with a considerable knowledge of the classics. There he studied with successful ardour, and at the same time subjected himself to a rigid system of fastings, vigils, self-examinations, and other pious exercises. An impediment in his speech induced him at one time to forego his intention of entering the church, and to commence the study of medicine. This infirmity, however, was soon afterwards overcome; and accordingly, after graduating, he began to preach in 1680. In the same year he was appointed assistant to his father in the North Church of Boston. Cotton Mather now became one of the most zealous of ministers. He discharged his professional duties most faithfully, published numerous sermons and books on practical religion, and assiduously amassed materials for intended treatises. At the same time he set himself to acquire several modern languages, and among others the Iroquois Indian. Nor did he refrain from interfering in civil affairs. A sharer in the superstitions of his age, he was a confident believer in witchcraft; and imagining that there were in the town of Boston some devotees of the evil one, he laboured with his usual honest zeal to detect them. A book of his, entitled *Memorable Providences relating to Witchcraft and Possessions, with Discoveries and Appendix*, 8vo, Boston, 1689, excited a great ferment both in England and America, and was the chief cause of that series of executions for Satanic intercourse known as the "Salem Tragedy." The tide of opinion, however, was now setting in that was destined to sweep all such superstitions away, and Cotton Mather in vain attempted to stem it by his work entitled *The Wonders of the Invisible World*, 8vo, Boston, 1693. So far had he now fallen in the public estimation, that though generally regarded as pre-eminent among his countrymen for learning and genius, he was twice passed over in the election of a president to Harvard College. Yet he continued with unabated earnestness to toil for the general welfare of his fellow-men; and in 1721 he was the first to introduce into America the practice of inoculation. He died in February 1728. Cotton Mather was the first American who was elected a fellow of the Royal Society of London. Of his numerous works his *Magnalia Christi Americana*, London, 1702, is the greatest; and his *Directions to a Candidate for the Ministry*, Boston, 1726, is the best known.

MATHER, *Increase*, D.D., the father of the preceding, was born at Dorchester, Massachusetts, in June 1639. He was enrolled at the age of twelve a student of Harvard College, where he graduated in 1656, and immediately proceeded to Dublin to complete his studies at Trinity College. Soon after his return to America in 1661 he was chosen minister of the North Church, Boston. The native energy and unflagging zeal of Increase Mather had now obtained full scope. He discharged his ministerial duties with fidelity, spent the greater part of the day in his study, published numerous sermons and other works, and was the acknowledged leader in the political discussions of the community. In 1685 he was appointed president of Harvard College; and in 1688 he was despatched to England as agent for the province, to procure redress of grievances. On his return his services were rewarded with the thanks of the House of Representatives. In 1701 he resigned his presidentship, as he thought that its duties were incompatible with those of his pastorate. He died at Boston in August 1723. The best known works of Increase Mather are,—*History of the Wars with the Indians in New England*, London 1676; and *Remarkable Providences*, reprinted as a volume of Russell Smith's Library of Old Authors, 8vo, 1856.

MATHEWS, CHARLES, an eminent comedian, was the son of a bookseller in the Strand, and was born in London on the 28th June 1776. After receiving his education at the Merchant Tailors' school, he was apprenticed to his father's business. But his early-developed love for mimicry had grown into a passion for the stage; and after playing several times as an amateur, he eventually, in 1794, engaged himself as a professional comedian at the Theatre Royal, Dublin. In the course of a year, however, the injustice of a cruel manager, and the pinchings of extreme poverty, had cooled his enthusiasm so much that he set out for England, bent upon spending the rest of his life in his father's shop. At Swansea the stage-fever relapsed, and there Mathews played for nearly three years with great popularity. Meanwhile he had married in 1797 the daughter of Dr Strong, a physician at Exeter. He removed in 1798 to the theatre at York, and by his careful study and ready talents soon became a great favourite with the play-goers of that city. But the gratification resulting from his public success was neutralized by domestic misfortune. Feeble health, pecuniary embarrassments, and the death of his wife, simultaneously overwhelmed him; and not until he had received, in 1802, a flattering invitation to become a member of the Haymarket Theatre, London, did he resume his wonted gaiety. After marrying his second wife, Miss Anne Jackson, a member of the York company, Mathews repaired to London in 1803. His success continued to increase during two seasons at the Haymarket, and afterwards at Drury Lane. On the destruction of the latter theatre by fire in 1809, he removed with the rest of the company to the Lyceum, and there he acquired additional fame by his personation of Maw-worm in *The Hypocrite.* In 1811 he set out on a provincial tour; and on his return to London in 1812 he resumed his place at the Haymarket. A severe fall from his tilbury in 1814, lamed him for the rest of his life. In 1818 the genius of Mathews, hitherto cramped by the shallow characters he had been employed to personate, gained full scope in his entertainment entitled "Mathews at Home." By a series of comic songs, personations, ludicrous adventures, and imitations of well-known actors, he filled the English Opera-House to overflowing for forty successive nights. He had thus, by one rapid stroke, gained the greatest histrionic honours, and was now considered unrivalled in the versatility of his comic powers. During the four following seasons he continued his entertainments in the same theatre with unabated applause. In 1822 he set out on a professional visit to the United States; and on his return to London in 1824, he mimicked the peculiarities of that country with inimitable effect in his "Trip to America." He continued his entertainments every season in the English Opera-House until he became, in 1828, joint-proprietor with Mr Yates of the Adelphi Theatre. In compliance with the urgent request of the American theatres, Mathews revisited America in 1834, and performed his famous "Trip," to crowded audiences, in several of the largest cities. His sinking health, however, compelled him to accelerate his return, and he died at Plymouth on the 28th June 1835.

Possessing in the highest degree a plastic countenance, a flexible voice, and a power of rapid and keen discernment, Charles Mathews stood alone in the art of mimicry. His imitation of the voice, of the physical peculiarities, of the very sentiments and mind of his subject, approached as nearly as possible to complete identification. Almost as wonderful was his dramatic power of inventing new characters. Those in his entertainments "At Home" were all designed by himself; and each of them had the finish and individuality of a true transcript from nature. The gentlemanly bearing, upright conduct, and social worth of Charles Mathews, combined with his genius to introduce him into the most select society; and he numbered among his personal friends such men as Coleridge and Charles Lamb. His son, the eminent comedian of the present day, has inherited, along with his father's name, no small portion of his talents.

MATINA, a river of Central America, in Costa Rica, formed by the union of the Chirripo and Barbilla, flows eastward, and discharges itself into the Atlantic. The Matina flows smoothly over a bed unbroken by rocks, and is navigable during the whole of its course; as also are its tributary streams for some distance above their junction. The river is subject to annual inundations, which take place generally in December and January, though sometimes at earlier or later seasons, and which leave a deposit of thick and rich mud, to which the neighbouring country owes much of its fertility and the luxuriance of its vegetation. Ships can pass into this river from the port of Moin by means of a canal called the Baya.

MATLOCK, a village of England, county of Derby, on the Derwent, 17 miles N. by W. of Derby, and 144 N.W. of London. It stands in a beautiful position on the slope of a hill to the E. of the river, which is here crossed by a fine stone bridge. The church, an edifice in the English style, surmounted by a spire 129 feet high, is picturesquely situated on the summit of a perpendicular rock overlooking the Derwent. There are four other churches belonging to different denominations, and numerous commodious and handsome hotels and other establishments for the use of visitors. Matlock is much frequented by invalids and tourists for the sake of its medicinal springs and the beauty of the scenery. The springs were first brought into notice in 1698, and have since been much resorted to, being considered beneficial in nervous debility and other diseases. There are several curious caverns in the vicinity, from which, and from mines, stalactites and spars are obtained, which are manufactured by the inhabitants into various articles, and largely purchased by visitors. There is here also a museum containing many mineralogical specimens found in the neighbourhood. The inhabitants are chiefly employed in lead mines and quarries in the neighbourhood. Matlock Dale, which has a length of about 2 miles, is full of the most romantic scenery, and surrounded by steep and rugged hills. Pop. of the parish (1851) 4010.

MATSYS, or Messis, Quintin, an eminent painter, styled from his original vocation "The Blacksmith of Antwerp" was born in that city in 1460. At the age of twenty, according to the ordinary account, he became passionately attached to the daughter of a painter; and on being informed that her father would bestow her hand upon none but an artist, he resolved to acquire that qualification, and accordingly abandoned his trade. His first painting, it is said, was a portrait of his mistress, which raised him at once to the rank of a successful suitor and an eminent artist. He died at Antwerp in 1529. The paintings of Matsys, though rather hard and dry, are finished in their style and vigorous in their colouring. Some of his heads were thought by Sir Joshua Reynolds to be equal to those of Raphael. His masterpiece is the picture of the "Two Misers," now seen at Windsor.

MATTEI, Stanislao, a pupil of the celebrated Padre Martini, was born at Bologna on 10th February 1750. His love of music was early awakened by hearing the daily service in the church of the Cordeliers; and Padre Martini having remarked his close attendance, took an interest in the boy, and induced him to enter his own convent (that of St Francis) as a novice. There Mattei was taught music by Padre Martini, took the vows, and was ordained. He remained constantly with his master till the death of the latter, who left his books and manuscripts in the hands of his pupil, with the hope that Mattei would complete the fourth volume of the *Storia della Musica*. But Mattei probably felt his incompetency, for he never published any part of that volume. The writer of this article was introduced to Mattei in Feb. 1819, and had a good deal of conversation with the old man, who spoke with great affection of his master, a portrait of whom he kept in his bedroom. Speaking of his *quondam* pupil, Rossini, he said,—"I never could get him to *study* attentively, and therefore he often writes incorrectly; but he is full of talent, and his head works like a Vesuvius." Some notice of the library of Padre Martini has been taken in this work, under the article Burney. Mattei succeeded Padre Martini as chapel-master of St Francis' church, and produced a number of masses, motets, &c., most of which remain in manuscript at Bologna. He afterwards became chapel-master of St Petronio, and held that office till his death on the 17th May 1825. In 1804 he was appointed professor of musical composition in the Liceo of Bologna, and taught many pupils, among whom were Rossini, Morlacchi, Donizetti, &c. He was president of the Philharmonic Society of Bologna in 1791-94; and in 1808 became a member of the musical section of the Italian Institute of Arts and Sciences. On 24th January 1824 he was named one of the associates of the French Academy of the Fine Arts. His work on accompaniment and counterpoint is held in no esteem except for the musical examples, which are all well written. (G. F. G.)

MATTHEW, St, the Evangelist, was, according to Mark ii. 14, the son of Alphæus; and if it is correct, as is generally supposed, that Jacobus, or James, the son of Alphæus, was a son of Mary, the wife of Cleophas, who was a sister of the mother of Jesus, Matthew was one of the relatives of the Saviour. Matthew was at all events a man of humble birth, and held the office of a *portitor*, or inferior collector of customs, at Capernaum, on the Sea of Galilee, where he was either connected with the port of Capernaum, or collected the customs on the high road to Damascus, which went through what is now called Khan Minyeh, or the ancient Capernaum. In Mark ii. 14, and Luke v. 27, he is called Levi, and hence we conclude that he had two names. This circumstance is not mentioned in the list of the apostles (Matt. x. and Luke vi.); but the omission does not prove the contrary, as we may infer from the fact that Lebbæus is also called Judas in Luke vi. 16, in which verse the name Lebbæus is omitted. We are informed in Matt. ix. 9, how Matthew was called to be an apostle; yet we must suppose that he was previously acquainted with Jesus, since we read (Luke vi. 13), that when Jesus, before delivering the Sermon on the Mount, selected twelve disciples, Matthew was among their number. After this Matthew returned to his usual occupation; from which Jesus, on leaving Capernaum, called him away. After this event he is mentioned only in Acts i. 13. Clemens Alexandrinus (*Pædagog.* ii. 1) states that Matthew abstained from animal food, a circumstance which has led some writers to conclude that he belonged to the sect of the Essenes. But while it is true that the Essenes practised abstinence in a high degree, it is not true that they rejected animal food altogether. And even admitting the account in Clemens Alexandrinus to be correct, it proves only a certain ascetic strictness in the disciple, of which there occur not unfrequent vestiges in the habits of other Jews. According to another account, which is as old as the first century, and which occurs in Clemens Alexandrinus (*Strom.* vi. 15), Matthew, after the death of Jesus, remained about fifteen years in Jerusalem. This agrees with the statement in Eusebius (*Hist. Eccles.* iii. 24), that Matthew preached to his own nation before he went to foreign coun tries. Rufinus (*Hist. Eccles.* x. 9) and Socrates (*Hist. Eccles.* i. 19) state that he afterwards went into Ethiopia; and other authors mention other countries which he visited. Heracleon and Clemens Alexandrinus agree in the opinion that Matthew was one of those apostles who did not suffer martyrdom.

MATTHEW, *St, The Gospel of,* has been more strongly attacked with respect to its genuineness than any of the other three, both by *external* and *internal* arguments.

The most ancient testimony concerning Matthew's Gospel is that of Papias, who, according to Eusebius (*Hist. Eccles.* iii. 39), wrote as follows:—"Matthew wrote the sayings in the Hebrew tongue, but everybody interpreted them according to his ability." Doubts of different kinds have been raised whether this testimony could refer to our Greek Gospel of St Matthew. These doubts were particularly brought forward by Schleiermacher in the *Studien und Kritiken*, 1832, Heft 4; whose opinion was adopted by Schneckenburger, Lachmann, and many others. According to these critics, the apostle wrote only a collection of the remarkable sayings of Jesus; which collection was put into an historical form by a Greek translator. Dr Lücke has shown, however, that the testimony of Papias may be considered as referring to our Gospel of St Matthew. Those who deny the genuineness of this Gospel allege that in none of the Fathers before Jerome do we find any statement from which we could infer that they had seen the Hebrew Gospel of St Matthew; and that consequently we may consider as a mere conjecture the opinion of the Fathers, that our Gospel is a Greek translation of a Hebrew original. Jerome, in his *Catal. de Viris Illustr.* (cap. iii.), reports that the Hebrew Gospel of St Matthew was preserved in the library at Cæsarea, where he took a copy of it; and in his commentary on Matt. xii. 13, he says, that he translated this Hebrew Gospel into Greek. Accordingly, Jerome's statement respecting the *Evangelium secundum Hebræos* may be taken as a confirmation of the account of Papias, that Matthew wrote his Gospel in Hebrew. If this be the fact, the question must arise whether our Greek Matthew is a correct translation of the Hebrew. The words of Papias seem to imply that in his days there was no Greek translation in existence; a circumstance which has induced many critics to question his account, and to suppose that the original text was Greek. Such is the opinion of Erasmus, Œcolampadius, Calvin, Beza, Lardner, Guerike, Harless, and others. It is by no means improbable, however, that after several inaccurate and imperfect translations of the Aramæan original came into circulation, Matthew himself was prompted by this circumstance to publish a Greek translation, or to have his Gospel translated under his own supervision. It is very likely that this Greek translation did not soon come into general circulation, so that Papias may have remained ignorant of its existence. On summing up what we have stated, it appears that the external testimonies clearly prove the genuineness of the Gospel of St Matthew. The authenticity, indeed, of this Gospel is as well supported as that of any work of classical antiquity. Not only was it early in use among Christians, but the apostolical fathers, at the end of the first century, ascribed to it a canonical authority. (See Polycarp, *Epist.* c. ii. 7; Ignatius, *Ad Smyrn.* c. vi.; *Ad Rom.* c. vi.; Clemens Romanus, *Epist.* i. c. xlvi.; Barnabas, *Epist.* c. iv.)

With respect to the *internal* arguments brought against the authenticity of this Gospel, it has been alleged that the representations of Matthew have not that vivid clearness which characterizes the narration of an eye-witness, and which we find, for instance, in the Gospel of John, and even in Mark and Luke; that he omits some facts which every apostle certainly knew. For instance, he mentions only the last journey of Christ to the passover at Jerusalem; and seems to be acquainted only with Galilee as the sphere of Christ's activity. It is further objected, that he relates unchronologically, and transposes events to times in which they did not happen; for instance, the event mentioned in Luke iv. 14–30 must have happened at the commencement of Christ's public career, but Matthew relates it as late as ch. xiii. 53, sq.; that he embodies in one discourse several sayings of Christ which, according to Luke, were pronounced at different times. He falls, it is asserted, into positive errors; for he seems not to know that the real dwelling-place of the parents of Jesus was at Nazareth, and that their abode at Bethlehem was only temporary; and disagrees with Mark in his account of the withered fig-tree, and in the time assigned for the purification of the temple. These circumstances have led Strauss and others to consider the Gospel of St Matthew as an unapostolical composition, originating, perhaps, at the conclusion of the first century; while some consider it a reproduction of the Aramæan Matthew, augmented by some additions; and others call it an historical commentary of a later period, made to illustrate the collection of the sayings of Christ which Matthew had furnished. (Comp. Sieffert, *Ueber die Aechtheit und den Ursprung des ersten Evangelii*, 1832; Schneckenburger, *Ueber den Urspung des ersten Evangelii*, 1834; Schott, *Ueber die Authenticität des Ev. Matth.* 1837.)

To these objections it may be replied, that the gift of narrating luminously is a personal qualification of which even an apostle might be destitute, and which is rarely found among the lower orders of people; that an *argumentum à silentio* must not be urged against the evangelists. The raising of Lazarus is narrated only by John; and the raising of the youth at Nain only by Luke; the appearance to five hundred brethren after the resurrection, which, according to the testimony of Paul (1 Cor. xv. 6), was a fact generally known, is not recorded by any of the evangelists. In the next place, there is no reason to suppose that the evangelists intended to write a chronological biography. On the contrary, we learn from Luke i. 4 and John xx. 31, that their object was of a more practical and apologetical tendency; and it is now generally admitted that, with the exception of John, the evangelists have grouped their communications more according to the subjects than according to chronological succession (com. Kern's *Abhandlung über den Ursprung des Evangelii Matthæi*, p. 51, sq.; Köster, *Ueber die Composition des Ev. Matth.* in Pelt's *Mitarbeiten*, Heft i.; Kuhn, *Leben Jesu*, t. i., *Beilage*.)

Again, if the evangelist arranges his statements according to subjects, and not chronologically, we must not be surprised that he connects similar sayings of Christ, inserting them in the longer discourses after analogous topics had been mentioned; for these discourses are not compiled by the evangelist, but always form the fundamental framework to which sometimes analogous subjects are attached. It depends, moreover, entirely upon the mode of interpretation, whether such positive errors as are alleged to exist are really chargeable on the evangelist. The difference, for instance, between the narrative of the birth of Christ, as severally recorded by Matthew and Luke, may easily be solved without questioning the correctness of either, if we suppose that each of them narrates what he knows from his individual sources of information. If these arguments should still appear unsatisfactory, they may be supported by adding the positive internal proofs which exist in favour of the apostolical origin of this Gospel. 1. The nature of the book agrees entirely with the statements of the Fathers of the church, from whom we learn that it was written for Jewish readers. None of the other evangelists quotes the Old Testament so often as Matthew, who, moreover, does not explain the Jewish rites and expressions, which are explained by Mark and John. 2. If there is a want of precision in the narration of facts, there is, on the other hand, a peculiar accuracy and richness in the reports given of the discourses of Jesus; so that we may easily conceive why Papias, *a parte potiori*, styled the Gospel of Matthew *λόγια τοῦ κυρίου, the sayings of the Lord.* Some of the most beautiful and most important sayings of our Lord, the historical credibility of which no sceptic can attack, have been preserved by Matthew alone (Matt. xi. 28-30; xvi. 16-19; xxviii. 20; comp. also xi. 2-21; xii. 3-6, 25-29; xvii. 12, 25, 26; xxvi. 13); and above all, the Sermon on the Mount, of which negative criticism grants that Luke's account is defective as compared with Matthew's, and that Luke gives as isolated sentences what in Matthew appears in beautiful connection. In short, the Sermon on the Mount, according to Matthew, forms the most beautiful and the best arranged whole of all the evangelical discourses. It may also be proved that in many particulars the reports of several discourses in Matthew are more exact than in the other evangelists; as may be seen by comparing Matt. xxiii. with the various parallel passages in Luke. Under these circumstances, it is surprising that the genuineness of this Gospel has not yet met with more distinguished advocates. The most important work in defence of the genuineness of Matthew is that of Kern, *Ueber den Ursprung des Evangelii Matthæi*, Tübingen, 1834. Next in value are Olshausen's *Drei Programme*, 1835; and the two *Lucubrationes* of Harless, 1840 and 1843. Even De Wette, in the fourth edition of his *Introduction*, p. 170, has ascribed only a qualified value to the doubts on this head. With regard to the *date* of this Gospel, Clemens Alexandrinus and Origen state that it was written before the others. Irenæus (*Adv. Hær.* iii. 1) agrees with them, but places its origin at the time when Peter and Paul were at Rome. Even De Wette grants (*Einleitung*, sect. 97) that it was written before the destruction of Jerusalem.

Among all the German commentaries on the first three Gospels, the best is that of Olshausen, English translation, Edinburgh, 1847. (On the whole subject of this article, see *An Introduction to the New Testament*, by Dr S. Davidson, vol. i., London, 1848.)

MATTHEW OF WESTMINSTER, a Benedictine monk of the abbey of Westminster, author of a Latin chronicle of great value, probably flourished during the early part of the fourteenth century, though some place him near the end of it. His work, which is said to have been formed very much upon the plan of that of Matthew Paris of the previous century, begins with the creation of the world, and continues to the death of Edward I. of England. In his preface he aspires to write the history of the whole world; but after the Heptarchy he is content to limit himself almost exclusively to Britain. After abridging the Bible in the early part of his work, he gives us a brief sketch of the history of Rome, with occasional reference to Greece; records the fabulous traditions of our own early times; tells the sad story of "old King Leyr;" relates the prophecy of Merlin; and so conducts the reader to the times of authentic history. Down to A.D. 1238 Matthew was much indebted to Roger of Wendover, whose chronicle stops at that date; but for the succeeding seventy-two years of his work he seems to have drawn entirely upon his own resources. After the Conquest his record of English affairs is exceedingly minute, and displays much industry and care; and in his relation of the wars of his own time, he displays a strong spirit of nationality, and striking powers of description. His narrative is ordinarily characterized by singular simplicity and directness, written with a careful eye to order and chronology, but filled with copious accounts of Romish miracles and other marvellous legends which, if not true, are at least sometimes amusing. With Hume and other modern historians he stands high as an authority on matters of fact. His chronicle is entitled *Flores Historiarum per Matthæum Westmonasteriensem collecti, præcipuè de rebus Britannicis, ab exordio Mundi usque ad annum Domini* 1307; folio, London, 1570. It was translated into English, by C. D. Yonge, for Bohn's Antiquarian Library, in 2 vols. 8vo, London, 1853.

MATTHEW, ST, an uninhabited island, situated off the western coast of Lower Siam, belonging to the Burmans. Long. 97. 30. E., Lat. 9. 35. N.

MATTHISSON, FREDERIC VON, a celebrated German lyric poet, was born at Hohendodeleben, near Magdeburg, in January 1761. As his father had died shortly before his birth, he was brought up by his grandfather, the Protestant minister of his native village. He attended the school of Klosterbergen, and studied theology at the university of Halle; but a decided bias for literature and philology induced him to abandon his intention of entering the church, and to become a private tutor. After residing in this capacity at Altona, Heidelberg, and Mannheim, he sojourned for two years on the Lake of Geneva, beside his friend the philosopher Bonstetten. He was then intrusted with the education of a merchant's son at Lyons. In 1792 Matthisson returned to his native country; and in 1794 he was appointed reader to the reigning princess of Anhalt-Dessau. In this capacity he spent the next fourteen years in visiting Italy, the Tyrol, and part of Switzerland. On the death of the princess in 1812 he entered the service of the King of Würtemberg, and was soon loaded with titles and honours. Following in the train of Duke William of Würtemberg, Matthisson again visited Italy in 1819, and lived for several months at Florence. He died at Wörlitz, near Dessau, in March 1831.

Among his countrymen Matthisson is a great favourite. His lyrics abound in tender sentiments and sweet rural pictures expressed in felicitous and harmonious verse. One of his pieces ("Adelaide") has been rendered doubly charming by the music of Beethoven. As a prose writer Matthisson is known by his *Erinnerungen*. He also published selections from the lyrical poetry of Germany, entitled *Lyrische Anthologie*, in 20 vols., Zurich, 1803-7. An edition of his works appeared in 6 vols., Zurich, 1825-29.

MATTO GROSSO, or **MATO GROSSO**, a province of Brazil, lying between Lat. 7. and 24. S., Long. 50. and 62. W., and bounded on the N. by the provinces of Para and Alto Amazonas, on the E. by that of Goiaz, on the S. by that of Parana, and on the W. by Bolivia; area estimated at 426,500 square miles. Of this extensive country little is known with accuracy, for it has been but little visited by Europeans, being covered to a great extent with dense forests, from which the province derives its name. It is traversed by several ridges of mountains, but these are of no great elevation. Great part of the surface is occupied by undulating table-lands. The principal mountain ridge runs from E. to W., and afterwards N.W., separating the waters that flow into the La Plata from those which go to swell the giant stream of the Amazon. This chain is known by different names in different places; being called the Serra dos Vertentes on the E., and the Parexis or Paricis on the W. and N.W.; while the whole bears the name of Cordillera Geral. Besides this, there are numerous branches from the central ridge in both directions, many of which have no distinctive names. The table-land on the N., which is called Canipos dos Paricis, is barren, and uninhabited by Europeans; while that of the Parana to the S. possesses large pastures. The principal rivers of the province are,—the Madeira and its tributary the Guaporé, the Juruenna, the Chingua, and the Araguaia, flowing to the N., and joining the Amazon and the Tocantins; and, flowing to the S., the Paraguay and the Cuiba. In many parts of the province gold and diamonds have been found; a circumstance which has induced the formation of settlements and mines; but these are now comparatively unproductive, and little cared for. Besides this, various other gems and minerals are found in different parts. Rock-salt and saltpetre are found, but they are not worked to any great extent; and although rich iron exists in great abundance, yet this metal has not attracted so much attention as the gold and precious stones, and is allowed to lie neglected. In many of the valleys the soil is very rich and fertile, producing rice, millet, cotton, sugar, tobacco, &c.; but comparatively little of the district is cultivated, owing to the thinness of the population. The natural productions of the country consist of timber of many different kinds, some of which are used for ornamental purposes; and gums, balsams, cacao, jalap, &c. Among the fauna of this country the principal are pumas, jaguars, deer, hares, &c. The climate is hot and tropical; and the rainy season extends from April to September, during which time the rivers overflow their banks, and fertilize the low-lying country in the neighbourhood. The inhabitants are chiefly native Indians; and they are occupied for the most part in hunting and pastoral employments. The commerce of the province is very small, and cannot be expected to make much progress as long as there are not better means of communication than at present exist. Mato Grosso is divided into two comarcas,—Cuiaba and Mato Grosso. It sends two members to the legislature of Brazil,—one to the Senate, and one to the Chamber of Deputies; and is governed by a provincial assembly of twenty members. The capital is Cuiaba, which, though a mere village, is the residence of an archbishop. The town of Mato Grosso, which was formerly called *Villa Bella*, is situated in the midst of wide plains on the Guaporé, and consists of low, wooden, tiled houses, which are arranged with considerable regularity. It contains churches and other public buildings, and has a population of 15,000. In the vicinity there are several mines. Pop. of the province, 180,000.

MATURIN, Charles Robert, a poet and romance writer, was born at Dublin in 1782, of a family of French extraction. After completing his education at Trinity College in his native city, Maturin took orders, and became a clergyman of the Established Church of Ireland, with the curacy of St Peter's for his preferment. His leisure hours were divided between the irksome duties of a classical tutor, by which he managed to augment his scanty income, and the much more congenial occupation of romance composition. He came before the public for the first time in 1807 as the author of a novel entitled *Fatal Revenge, or the Family of Montorio*, written in a terrific and gloomy style, after the manner of Monk Lewis, displaying some genius and much bombast, and strongly dashed with the mysterious colouring of the *Castle of Udolpho*. Having enjoyed considerable popularity by his efforts as a novelist, Maturin next directed his efforts to dramatic composition, and produced in 1816 a wild and powerful tragedy named *Bertram*, which, through the influence of Lord Byron and Sir Walter Scott, was performed at Drury Lane, where it met with surprising success. The Scottish novelist spoke of it as "one of those things which will either succeed greatly or be damned gloriously, for its merits are marked, deep, and striking, and its faults of a nature obnoxious to ridicule." Elated by his success, and rendered extravagant in his expectations by the L.1000 whch he realized through his tragedy, Maturin forgot to be provident, and plunged himself into inextricable embarrassments, from which the generous liberality of Scott and others could not rescue him. He prosecuted his literary projects, however, but found that to be haunted by bailiffs was not favourable for the development of his genius. His tragedy of *Manuel* accordingly, which appeared during the ensuing year, proved a very inferior production: "The absurd work," as Byron said, "of a clever man." Maturin continued his efforts in romantic fiction; and in addition to *The Milesian Chief*, and *The Wild Irish Boy*, previously published under the assumed name of "Dennis Jasper Murphy," he wrote *Women, or Pour et Contre*, and *Melmoth the Wanderer*, the wildest of his romances. The hero, a sort of absurd Dr Faustus, lives a century and a half, and by the help of the devil performs all manner of incredible adventures. The school of Ann Radcliffe reaches the culmination of loathsome horror and sickening extravagance in the person of this demoniac hero of Maturin's. "Eva," in *Women*, is the most simple and truthful of this author's delineations. *The Albigenses*, his last work, published in 1824 in 4 vols., proved tedious and uninteresting, possessing many of the defects of his previous works, and few of their excellences. His characters want variety, his humour is clumsy, and he has no genius for plot; yet his works display scenes of deep passion and touching pathos, coloured with the rich lights of a poetical imagination. In addition to the works already mentioned, Maturin published a tragedy called *Fredolpho*; a poem on *The Universe*; and a volume of sermons, London, 1819, characterized by much of the eloquence he is said to have possessed as a preacher. He died on the 30th October 1824.

MATY, Matthew, M.D., was born at Montfort, near Utrecht in Holland, in the year 1718. He was the son of a clergyman, and was originally intended for the church; but having turned his attention to physic, he took his degree of Doctor at Leyden, and in 1749 came to settle in England, where he secured the patronage of Lord Chesterfield. Maty began in 1749 to issue in French an account of the productions of the English press, printed at the Hague, under the name of the *Journal Britannique*,—a publication which continues to hold its rank amongst the best of the kind which have appeared since the time of Bayle. In 1758 he was chosen fellow of the Royal Society; and in 1765 he was appointed secretary to that eminent institution. He was also chosen principal librarian of the British Museum on the death of Dr Knight in 1772. He died after a lingering illness, August 2, 1776. He was an early and an active advocate for inoculation; and when there was a doubt entertained that one might have the small-pox even after inoculation, he tried it upon himself unknown to his family. Dr Maty's principal works were:—*Mémoire sur la Vie et sur les Ecrits de M. Ab. de Moivre*, 12mo, Hague; *Authentic Memoirs of the Life of Richard Mead, M.D.*, 8vo, London, 1755. His unfinished *Memoirs of the Earl of Chesterfield* were completed by his son-in-law, Mr Justamond, and prefixed to that nobleman's *Miscellaneous Works*, in 2 vols. 4to, 1777.

MAUBEUGE, a town of France, department of Nord, is situated on the Sambre, not far from the frontiers of Belgium. The town is well fortified, the defences being by the famous Vauban; and it has a manufactory of arms, founded by Louis XIV. in 1704. Maubeuge also has manufactures of ironmongery, cutlery, soap, &c.; and a considerable trade in coal, marble, and slates. The town traces its origin back to the seventh century, when an abbey was founded here by St Aldegonde. Situated near the frontier, this town has been an object of great contention, and has been taken no less than ten times since the fifteenth century, and finally by the Allies in 1815. Pop. 7328.

MAUCH CHUNK, a town in the state of Pennsylvania, North America, capital of Carbon county, is situated on a creek of the same name on the Lehigh River, 100 miles N.E. of Harrisburg. The surrounding country, though barren, is rich in coal and iron, which supplies Mauch Chunk with the most of its trade. The principal coal mines are about 9 miles W. of the town, and are reached by a railway. The original town is built in a narrow ravine near the river; but a new town is now rising on the top of the hill to the E. It contains a court-house, and other public buildings. Pop. (1850) 3500.

MAUCHLINE, a small town of Scotland, county of Ayr, is situated on an eminence not far from the River

Ayr, 7 miles S.E. of Kilmarnock, and 12 E.N.E. of Ayr. The town is well built, and contains an Established, a Free, and a United Presbyterian church, several schools, a public library, a savings-bank, and other institutions. The inhabitants are employed in weaving, shoemaking, and the manufacture of wooden snuff-boxes, for which Mauchline is famous. The river is crossed in the neighbourhood by several bridges, one of which, at Barskimming, is a structure of great elegance, consisting of a single arch 100 feet wide and 90 feet high. In the vicinity stands Mauchline Castle, an ancient edifice formerly in the possession of the Loudon family, who bear the title of Viscount Mauchline; and on Mauchline green there is a stone which commemorates the death of five Covenanters in 1685. But Mauchline derives its chief celebrity from being associated with the name of the poet Burns, who spent nine years of his life at the farm of Mossgiel in the neighbourhood. Pop. (1851) 1449.

MAULE, a river of Chile, rises in the Andes near the peak of Descabezado, and flows for 150 miles W. to the Pacific. It is navigable for a considerable part of its course; but it is obstructed by a bar at the month, where the surge is generally very violent. The principal tributary of the Maule is the Guanutil.

The province of the same name is bounded by this river on the N., and extends southward to the Itata, occupying a tract of ground of an undulating and hilly nature. It is productive of grain, wine, and tobacco, and affords excellent pasturage for cattle, in the rearing of which the inhabitants are chiefly employed. There is some trade in the exportation of wines and tobacco. The principal towns are Cauquenes, the capital; Constitucion, at the mouth of the Maule; and others. Pop. 118,309.

MAUMEE, a river of the United States of North America, is formed by the confluence of the St Joseph's and St Mary's Rivers at Fort Wayne, in the state of Indiana. It flows in a N.E. direction through that state and Ohio, till it falls into Maumee Bay, at the W. extremity of Lake Erie, after a course of 100 miles. It is navigable through all its extent for boats, and for steamers as far as Defiance, 60 miles up. The Wabash and Erie Canal extends along the banks through the whole course of the river.

MAUNDAY THURSDAY (called also *Shere Thursday*) is the Thursday immediately preceding Easter, on which a certain number of poor persons receive alms from the king or queen. Some conceive the name Maunday to be derived from *mandatum*, command; but others with stronger probability suppose it to be derived from the *maunds*, or large baskets from which it was customary to distribute the alms to the poor. It received the name "Shere Thursday," says an old homily, "for that in old Fathers' days the people would that day shere theyr hedes and clypp theyr berdes, and so make them honest agenst Easterday." The ceremonial of the Maunday, as practised by Queen Elizabeth in 1572, was as follows:—After thirty-nine poor people (the number equal to the years of her majesty's age) had been placed on forms by a long table in a hall prepared for the occasion; and after the preliminary arrangements had been gone through, "her majesty came into the hall, and after some singing and prayers made, and the gospel of Christ's washing of his disciples' feet read," her majesty "kneeling down upon the cushions and carpets under the feete of the poore women, first washed one foote of every one of them in soe many several basons of warm water and swete flowers, then wiped, crossed, and kissed them, as ther almoner and others had done before." Then after receiving food, clothing, and money from the queen, they retired. The last king who performed this ceremony in person was James II. We learn from the *Times* newspaper of April 16, 1838, that after the distribution of the queen's royal alms, which consisted of money and clothing, to the Maunday men and women, by Mr Hanby, at the Almonry Office, "they also received L.1, 10s., a commutation *instead of the provisions heretofore distributed.*" Nor was this custom confined to the sovereign; for we find that Cardinal Wolsey in 1530 "made his Maundy;" and in the Earl of Northumberland's household book of 1512, we have an enumeration of "al mauner of things yerly yeven by my lorde of his Maundy." The same ceremony is kept up in German Catholic countries by the court, under the name of *Fusswaschung*, or "the washing of the feet;" and Dr E. D. Clarke (*Travels in Russia*, 1810, i. 55) witnessed "the Archbishop of Moscow washing the feet of the apostles" on the Thursday immediately preceding Easter. (Brand's *Popular Antiquities*, vol. i., p. 142.)

MAUPERTUIS, Pierre-Louis Moreau de, a celebrated French academician, was born at St Malo in the year 1698. At the age of sixteen he was placed under the eminent professor of philosophy M. le Blond, in the college of La Marche at Paris, where he displayed a peculiar aptitude for mathematical studies, and particularly for geometry. He entered the army at the age of twenty, and first served in the Gray Musqueteers; but in the year 1720 his father purchased for him a company of cavalry in the regiment of La Roche-Guyon. He remained only five years in the army, during which time he pursued his mathematical studies with great vigour and success. In the year 1723 he was received into the Royal Academy of Sciences, and read his first performance, which was a memoir upon the construction and form of musical instruments (15th November 1724). During the first years of his admission he did not wholly confine his attention to mathematics; he likewise turned his attention to natural philosophy, and made ingenious observations and experiments upon animals. Maupertuis made a pilgrimage to the country which gave birth to Sir Isaac Newton; and during his residence in London he became as zealous an admirer and follower of that philosopher as any one of his own countrymen. On his return, he visited Basle in Switzerland, where he formed a friendship with John Bernoulli which continued till his death. Returning to Paris, he applied himself to his favourite studies with greater zeal than ever, of which abundant evidence is to be found in the Memoirs of the Academy from the year 1724 to 1736. The most sublime questions in geometry and the relative sciences were handled with that peculiar elegance, clearness, and precision, so remarkable in all his writings. In the year 1736 he was sent by the King of France to the polar circle to measure a degree of the meridian, in order to ascertain the figure of the earth, accompanied by MM. Clairaut, Camus, Le Monnier, the Abbé Outhier, and Celsius the celebrated professor of astronomy at Upsal. This distinction rendered him so famous that at his return he was admitted a member of almost every academy in Europe. In the year 1740 Maupertuis received an invitation from the King of Prussia to go to Berlin, which was too flattering to be refused. Having followed his Prussian majesty into the field to witness the battle of Mollwitz, his horse, during the heat of the action, ran away with him, and falling into the hands of the enemy, he was carried prisoner to Vienna, where he received distinguished honours from their imperial majesties. On his return to Paris, Maupertuis was in 1742 chosen director of the Academy of Sciences. In 1753 he was received into the French Academy, which was the first instance of the same person being at the same time a member of both the academies at Paris. He again assumed the character of a soldier at the siege of Fribourg, and was employed, on the surrender of that citadel, to carry the news to the French king. Having in 1744 married Mademoiselle de Borck, a lady nearly related to M. de Borck, then minister of state at the court of Berlin, Maupertuis took up his residence at that city. In the year 1746 he was chosen president of the Royal Academy of Sciences at Berlin; and soon afterwards was honoured with the Order of Merit. However, all these accumulated honours and advantages only furnished new allurements to labour and application. Nor did he confine himself solely to mathematical studies; metaphysics, chemistry, botany, polite literature, all shared his attention, and contributed to his fame. At the same time his temper was none of the best, and he had the misfortune to be engaged in several quarrels. He had a dispute with Koenig, the professor of philosophy at Franeker, and another of a more serious kind with Voltaire. The former unjustly charged Maupertuis with plagiarizing from Leibnitz; and the latter, with his accustomed wit and satire, espoused the cause of the German professor. The dispute became so serious that Maupertuis found it expedient in 1753 to quit the court of Prussia. Maupertuis's constitution had long been considerably impaired by the fatigues of various kinds in which his active mind had involved him; indeed, to the amazing hardships he had undergone in his northern expedition most of his future bodily sufferings may be traced. Yet his mind seemed still to possess the greatest vigour; for the best of his writings were produced, and his most sublime ideas developed, during the time of his confinement by sickness, when he was unable to occupy his chair as president at the academy. He took several journeys to St Malo in quest of health; and after visiting Toulouse and Neufchatel, he at length arrived at Basle on the 16th of October 1758, where he was received by his friend John Bernoulli and his family with the utmost tenderness and affection. He at first found himself much better there than he had been at Neufchatel; but this amendment was of short duration; for, after languishing here many months, he died in 1759.

The works of Maupertuis were collected into 4 volumes 8vo, and published in 1756 at Lyons, where a new and elegant edition was also printed in 1768. These consist of—*Essai de Cosmologie*, first published at Berlin in 1748; *Discours sur la Figure des Astres*, first published in 1732; *Essai de Philosophie Morale*, in which he maintains that the sum of evil surpasses that of good; *Réflexions Philosophiques sur l'Origine des Langues et la Signification des Mots*; *Venus Physique, or an Exposition of the System of Generation*; *Système de la Nature*, first published in 1751, and which may be considered as the sequel of the preceding work; *Lettres*, on various subjects; *Eléments de Géographie*, published at Paris in 1742, and containing an exposition of the means for determining the figure of the earth; *Relation d'un Voyage fait par ordre du Roi au Cercle Polaire*, printed at Paris as early as 1738; *Relation d'un Voyage au fond de la Laponie*; *Lettre* on the Comet of 1742; *Discours Académiques*, pronounced in the French and Prussian Academies; *Mémoire sur la moindre quantité d'Action*; *Astronomie Nautique*, a work much praised when it first appeared, but now little read; *Parallaxe de la Lune*; *Mésure du Degré du Nord*. Besides these treatises, Maupertuis was the author of a great number of papers, printed partly in the Memoirs of the French Academy of Sciences, and partly in those of the Academy of Berlin.

MAURETANIA, an ancient kingdom of Africa, bounded on the W. by the Atlantic Ocean, on the S. by Getulia or Libya Interior, and on the N. by the Mediterranean, and comprehending the greater part of the kingdoms of Fez and Morocco. Its ancient limits are not exactly mentioned by any historian; nor can they now be ascertained by modern observations, these kingdoms being but little known to Europeans.

This country was originally inhabited by a people called *Mauri*, concerning the etymology of whose name authors are not agreed. It is probable, however, that the country, or at least great part of it, was first called *Phut*, since it appears from Pliny, Ptolemy, and St Jerome, that a river and territory not far from Mount Atlas went by that name. It likewise appears, from the Jerusalem Targum, that part of the Mauri may be deemed the offspring of Lud, the son of Misraim, since his descendants, mentioned in Genesis, are there called *Mauri*, or *Mauritani*. It is certain that this region, as well as the others to the eastward of it, had many colonies planted by the Phœnicians. Procopius tells us that in his time two pillars of white stone were to be seen containing the following inscription in the Phœnician language and character:—"We are the Canaanites who fled from Joshua the son of Nun, that notorious robber." Ibnu Rachic, or Ibnu Raquig, an African writer cited by Leo, and also Evagrius and Nicephorus Callistus, make the same statement.

The Mauretanians were, according to Ptolemy, divided into several cantons or tribes. The Metagonitæ were situated near the Straits of Hercules, now those of Gibraltar; the Saccosii, or Cocosii, occupied the coast of the Iberian Sea; and under these two petty nations the Masices, Verues, and Verbicæ or Vervicæ, were settled. The Salisæ or Salinsæ were situated lower, towards the ocean; and still more to the south were the Volubiliani. The Maurensii and Herpiditani possessed the eastern part of this country, which was terminated by the Mulucha. The Angaucani or Jangacaucani, Nectiberes, Zagrensii, Baniubæ, and Vacuntæ, extended from the southern base of Ptolemy's Atlas Minor to his Atlas Major. Pliny mentions the Baniuræ, whom Father Hardouin takes to be Ptolemy's Baniubæ; and Mela speaks of the Atlantes, whom he represents as possessing the western part of this district.

The earliest Prince of Mauretania mentioned in history is Neptune; and next to him were Atlas and Antæus his two sons, both famous in the Grecian fables on account of their wars with Hercules. Antæus, in his contention with that hero, seems to have behaved with great bravery and resolution. Having received reinforcements of Libyan troops, he cut off numbers of Hercules's men. But that celebrated commander, having at last intercepted a strong body of Libyans sent to the relief of Antæus, inflicted on him a total overthrow, in which both he and the greater part of his forces were put to the sword. This decisive action put Hercules in possession of Libya and Mauretania, and consequently of the riches of these kingdoms. Hence arose the fable that Hercules, finding that Antæus, a giant of enormous size with whom he was engaged in single combat, received fresh strength as often as he touched his mother earth when thrown upon her, at last lifted him up in the air and squeezed him to death. Hence likewise may be deduced the fable which intimates that Hercules took the globe from Atlas upon his own shoulders, overcame the dragon which guarded the orchards of the Hesperides, and made himself master of all the golden apples it produced, which were probably the treasures which fell into Hercules's hands upon the defeat of Antæus; the Greeks giving to the oriental word מאל, *riches*, the signification affixed to their own term *μηλα*, *apples*.

With regard to the age in which Atlas and Antæus lived, the supposition of Sir Isaac Newton seems to be the most probable. According to that illustrious author, Ammon, the father of Sesak, was the first King of Libya, or of that vast tract extending from the borders of Egypt to the Atlantic Ocean, the conquest of which country was effected by Sesak in his father's lifetime. Neptune afterwards excited the Libyans to a rebellion against Sesak, and slew him, and then invaded Egypt under the command of Atlas or Antæus, the son of Neptune, Sesak's brother and admiral. Not long after, Hercules, the general of Thebais and Ethiopia, reduced a second time the whole territory of Libya, having overthrown and slain Antæus near a town in Thebais, from that event called *Antæa* or *Antæopolis*. This happened about a thousand years before the birth of Christ.

From the defeat of Antæus nothing remarkable occurs in the history of Mauretania till the times of the Romans, who at last brought the whole kingdom under their jurisdiction. With regard to the customs and manners of this people, it would seem, from what Hyginus insinuates, that they fought only with clubs, until one Belus, the son of Neptune (as that author calls him), taught them the use of the sword. Sir Isaac Newton is of opinion that this Belus was the same with Sesostris, King of Egypt, who overran a great part of the then known world. All persons of distinction in Mauretania went richly attired, wearing gold and silver on their clothes, and bestowed great care on the ornamenting of their persons. The Mauretanian infantry in time of action used shields made of elephants' skins, being clad in those of lions, leopards, and bears, which they kept on both night and day. The cavalry of this nation were armed with broad, short lances, and carried targets or bucklers made of the skins of wild beasts. They used no saddles. Their horses were small and swift, had wooden collars about their necks, and were so much under the command of their riders that they followed them like dogs. The habit of these horsemen was not much different from that of the foot already mentioned; they constantly wore a large tunic of the skins of wild beasts. The Phutæi, of whom the Mauretanians were a branch, were eminent for their shields, and the excellent use they made of them, as we learn from Homer, Xenophon, Herodotus, and Scripture. Nay, Herodotus seems to intimate that the shield and helmet came from them to the Greeks.

Notwithstanding the fertility of their soil, the poorer sorts of the Mauretanians never took care to manure the ground, being strangers to the art of husbandry, but roved about the country in a wild and savage manner, like the ancient Scythians or *Arabes Scenitæ*, living in tents, or *mapalia*, inconveniently small. Their food was corn, herbage, &c., which they frequently ate green without any manner of preparation, being destitute of wine, oil, and all the elegancies as well as many necessaries of life. Their habit was the same both in summer and winter, consisting chiefly of a coarse, thick garment, and over it a rough tunic, which answered probably to that of their neighbours the Numidians. Most of them lay every night upon the bare ground, not unlike the Kabyles and Arabs of the present day. If the most approved reading of Horace may be admitted, the Mauretanians shot poisoned arrows, which clearly intimates that they had some skill in the art of preparing poisons, and were excellent bowmen. This last observation is countenanced by Herodian and Ælian, who affirm that they were in such continual danger of being devoured by wild beasts, that they durst not stir out of their tents without their darts. Such perpetual exercise must have rendered them exceedingly skilful in hurling that weapon. The Mauretanians sacrificed human victims to their deities, like the Phœnicians, Carthaginians, and other nations. The country people were extremely rude and barbarous; but those inhabiting cities must have had at least some acquaintance with the literature of the several nations from whom they derived their origin. That the Mauretanians had some knowledge of naval affairs seems probable, not only from the intercourse they had with the Phœnicians and Carthaginians, as well as the situation of their country, but likewise from the statement of Orpheus or Onomacritus, who asserts that they had made a settlement at the entrance into Colchis, to which place they came by sea. To magic and sorcery, divination and witchcraft, they appear to have applied themselves in very early times. Cicero and Pliny say that Atlas was the inventor of astrology and the doctrine of the sphere, which he first introduced into Mauretania. This, according to Diodorus Siculus, gave rise to the fable of Atlas bearing the heavens upon his shoulders. The same author relates that Atlas instructed Hercules in the doctrine of the sphere and astrology, or rather astronomy, and that the latter afterwards brought these sciences into Greece.

MAURICE, THOMAS, a learned oriental historian, the son of the head master of Christ's Hospital school in Hertford, was born at that town about 1753. By his father's death he was left at an early age to the care and tuition of Dr Parr, then master of an academy at Stanmore. In his nineteenth year he repaired to Oxford, and was enrolled at St John's College, but subsequently removed to University College. There he produced a metrical version of *Œdipus Tyrannus*, and several original poems; and began to cultivate, under his tutor, Lord Stowell, that taste for historical research which afterwards led him into notice. After graduating as B.A. he was appointed curate of Woodford in Essex, a charge which he resigned in 1785 for a smaller pastorate at Epping. His *Indian Antiquities* began to appear in 1791, and was completed in 7 volumes in 1797. *The History of Hindustan*, his other great work which he had commenced to publish in 1795, was finished in 3 volumes in 1799. Meanwhile, Earl Spencer had appointed him in 1798 to the vicarage of Wormleighton in Warwickshire. In 1799 Maurice was installed assistant librarian to the British Museum; and in the following year he received the pension left vacant by the death of Cowper. The 2 volumes of his *Modern History of India* appeared in 1802 and 1804 respectively. In this latter year he was presented by the Lord Chancellor to the vicarage of Cudham in Kent. A second edition of his *History of Hindustan* appeared in 1821. He died in March 1824.

MAURICE *of Nassau*, the son of William I., Prince of Orange, was born in 1567, was elected stadtholder of the United Provinces in 1584, succeeded his brother as Prince of Orange in 1618, and died in 1625. (See HOLLAND.)

MAURICIUS, FLAVIUS TIBERIUS, Emperor of Constantinople, descended from an old Roman family, was born at Arabissus in Cappadocia about A.D. 539. His youth was spent in the camp; but as the sword was the only weapon of influence he could wield, he remained for a long time in obscurity. The sagacious Tiberius, however, on his accession to the throne in 578, discovered the eminent talents of the poor soldier of fortune, and appointed him to supersede Justinian in the conduct of the war against the Persians. Maurice repaired to the quarters of the army in Mesopotamia, and began his generalship by attempting to restore the severity of the old Roman discipline; then facing the enemy in the open field, he drove them out of Mesopotamia, and ended the first campaign by penetrating beyond the Tigris. After making a bold inroad into Media, he completely humbled the Persian power in two decisive battles, and in 582 entered Constantinople in triumph. In the same year Tiberius died, after bequeathing his crown to Maurice, and bestowing upon him the hand of his eldest daughter Constantina. Mature in age, and well-tried by experience, the new emperor began his reign amid the general rejoicing of his subjects. No sooner had he sat down on the throne, than the Persians, under their king Hormisdas, the son of Chosroes, revolted, and defeated John Mystacon, the general of the imperial forces. Other reverses in the following year induced Maurice in 584 to send out his brother-in-law Philippicus to supersede Mystacon. But this general, though at first successful in checking the inroads of the enemy, was at last defeated, and obliged to retreat in confusion. He was stripped of his command in 588 by the order of Maurice; but a dangerous revolt among the soldiers caused him to be restored to his former office, only to suffer another defeat and another degradation in 589. His successor, Comentiolus, would have fallen into the same mishaps had not Heraclius virtually assumed the command, and retrieved the Roman fortunes by the brilliant victory of Sisarbene. The rebellion against King Hormisdas in 590 withdrew the hostility of the Persians, and restored tranquillity to the Asiatic provinces. That tranquillity was confirmed by an event which happened in the subsequent year. Chosroes, the son of Hormisdas, driven into exile by Baram, the leader of the rebel

Persians, sought refuge in the Roman territory, and sent a letter to the emperor imploring assistance for the recovery of his ancestral throne. Moved by the deepest generosity, Maurice presented the royal fugitive with a diadem and a large sum of money, and sent him back, under the protection of a large army, to demand his father's sceptre. His entrance into Persia revived the loyalty of his subjects; and the insurgent Baram, deserted by nearly one-half of his troops, was completely routed at Balarath. Thus restored to his father's throne, Chosroes was ever afterwards a faithful friend of Maurice.

Scarcely had war been quelled in one part of the empire when it began to break out in another. The prowling hordes of the Avars, under their chagan or khan, had for some time menaced the European provinces, and had now become a scourge that could no longer be tolerated. Accordingly, Maurice threw off the sloth that had for two centuries been considered a necessary part of imperial state. He placed himself at the head of the entire force of the empire, set out on the march toward the hostile territory, and would have faced all the hardship and peril of the field, had not the remonstrances of his subjects, and some unfavourable omens, induced him to return to Constantinople. The command then devolved upon Priscus, and afterwards upon the emperor's brother Peter; but the latter proved weak and cowardly, and the former was restored in 598. Not so successful as was expected, Priscus was superseded in 600 by Comentiolus. This weak-minded and cowardly impostor was worsted by the enemy on every side. In one battle 12,000 Romans were captured, and greater misfortunes were impending, when the brave Priscus, resuming the command, defeated the Avars in five successive battles, and drove them before him as far as the Danube. Meanwhile Maurice, for some reason unknown, had refused to ransom the prisoners taken by the khan of Avars at the defeat of Comentiolus, and had left them to be butchered in cold blood. At this inhumanity a spirit of revenge had been excited among the pampered and self-willed soldiers of the imperial army, and only waited for an opportunity to vent itself in open revolt. This opportunity was now given by the infatuated emperor himself. In 602 he ordered his army to cross the Danube, and to winter in the Avarian territory. Crying out that they were now doomed to be butchered like their comrades, the soldiers threw off their allegiance, massacred the faithful adherents of the emperor, and placing Phocas, a centurion, at their head, hastened by forced marches towards Constantinople. The report that the army was approaching raised an insurrection in the capital; and Maurice, during a night of general rapine and consternation, escaped by sea with his wife and children, and took refuge in the church of St Autonomus, near Chalcedon. There the emissaries of Phocas soon afterwards found him bending under despair and bodily disease. They dragged him from his sanctuary, and murdered five of his sons while he stood by uttering pious ejaculations. He met his own fate with firmness on the 27th November 602. The bodies of the father and sons were thrown into the sea, and their heads were exposed on pikes in the streets of Constantinople.

The Emperor Maurice was a good man and a wise ruler. Strong self-command, an affectionate disposition, and sincere piety, marked his private conduct. His public authority was always exerted in lightening taxes, in enforcing beneficial laws, in patronizing art and learning, or in repelling foreign invasion. It was his misfortune to fall upon an age in which his economy was mistaken for avarice, and his military discipline for cruelty. A Greek treatise which he wrote on military science was translated into Latin, and published, along with Arrian's *Tactica*, by John Scheffer, Upsala, 1664, 8vo. There is a Life of Maurice by Theophylactus Simocatta, a writer of the seventh century.

MAURITIUS, or ISLE OF FRANCE, an island lying in the Indian Ocean, between 57. 17. and 57. 46. E. Long and 19. 58. and 20. 32. S. Lat. It lies 400 miles E. of the island of Madagascar, and 120 miles N.E. of the island of Bourbon, 2327 miles from the Cape of Good Hope, and 9500 miles from England *via* Suez and Aden. It extends from N. to S. 36 miles, from E. to W. 32 miles; comprising an area of 432,680 superficial acres, or 676 square miles. Its form is elliptical; the greatest diameter of the oval is 63,780 yards, and its breadth 44,248. The island is encircled by a belt of coral reefs, which makes the approach to it dangerous.

Mauritius is one of the most romantic and picturesque-looking islands in the Eastern Hemisphere. The northern is more elevated than the southern extremity; the land rises gradually from the shore to the interior. The centre of the island is intersected by a chain of mountains, with spurs radiating to the coast. There are three principal ranges of mountains, varying from 1800 to 2800 feet in height above the level of the sea, and for the most part covered with timber. The form of many of these mountains is grotesque and singular; the great chain called the Pouce, the summit of which is 2484 feet high, is so named from its supposed resemblance to the human thumb. On the same chain is a mountain called the Peterbote, 2520 feet in height, which has been frequently ascended, and is terminated by an obelisk or spire of naked rock, on the top of which reposes an immense globular mass of stone, larger than the point of the pyramid on which it is balanced. The mountains abound in curious caverns of considerable extent. Both the appearance of the island and the nature of its material indicate volcanic origin. In the centre of the island is an elevated plateau called Vaconas or Vacois, 1200 feet above the level of the sea; in the middle of this plain is a mountain of sugar-loaf form called Piton du Milieu, 1812 feet high. There are other mountainous ranges which slope down gently towards the sea, which are named Faience, Grand Port, Corps de Garde, Savanne, Rivière Noire, Rempart, and Pouce.

The Rivers Tamarin and Rempart run parallel to each other, receiving as affluents the lesser streams which flow around the Lake Vaconas. In the rainy season they are overwhelming torrents, which, in their course to the sea, form very beautiful cascades; in the dry season they are little more than brooks. The other rivers are the Latanier, Plain Wilhems, Moka, Great and Little Black River. One of the natural curiosities of the island is the lake called Mare aux Vaconas or Vacois, named from the vaconas (*Pandanus utilis*) by which it is encircled. It is surrounded by many acres of marshy and swampy ground, as its name implies, through which many streams, flowing into its centre, form a lake, which is well stocked with cray-fish, prawns, and eels of enormous size, and a small red fish called *damairie*, originally brought from China. Another freshwater lake is the Grand Bassin, a circle whose diameter is somewhat less than half a mile, surrounded by precipitous rocks rising perpendicularly from their base to a considerable height. In the most elevated of the central tracts, a league further E. than the Grand Bassin, is a lake called Mare aux Joncs.

Geologically the island presents all the appearances of volcanic origin. The rocks rise in strata from the shore to the centre of the island, upon whose plain stand out many rocky mountains composed of ferruginous rocks and a greyish lava, which, when decomposed, produce a soil of an argillaceous description, intermingled with oxide of iron. It has been surmised that there is some cavernous communication with the island of Bourbon, as the eruptions of its mountains are sensibly perceptible at Mauritius. From its volcanic formation, it abounds with numerous caverns, ravines, and rugged precipices. It contains some iron mines, which were once extensively wrought.

The climate is salubrious and agreeable, but at certain periods of the year rather hot. The heat, however, is moderated by the sea-breeze. At all times the temperature of the elevated districts, especially of Plain de Wilhems, is pleasant and refreshing, the thermometer varying from 70° to 80° Fahr.; while below, in Port Louis, it varies from 90° to 96°. There are four seasons at the Mauritius: the first commences in May, accompanied by rain and winds from the S.E.; the second with September or October;—the sun at this time approaching the zenith, causes squalls and winds till December, when the third season begins; this is terminated in March, when the fourth or last season commences, lasting about eight weeks. In the third season, namely, from December to March, the island is often visited by violent and most destructive hurricanes, accompanied by torrents of rain and gusts of wind, shifting round all the points of the compass, and causing great damage to the shipping, houses, and sugar plantations. These gales of wind last about eight hours; but of late years they have been less frequent and violent than heretofore, arising from the greater dryness of the atmosphere, in consequence of the island having been cleared of its forests.

The soil of this island is in many places very rich and fertile, of a reddish colour, highly impregnated with iron. The surface of the ground is covered with large stones, which render the use of a plough impracticable, so that it is prepared for crops by the hoe. In many districts of the island it is composed of mould, clay, and marshy plains, and is throughout generally highly productive and fertile. The chief, and it may be said the only, production of the island is sugar. Coffee and rice are grown, but in small quantities, not sufficient for the consumption of the colony. Indigo, cotton, and spices, have been successfully cultivated. An agricultural society was formed in 1853 at the Mauritius by the principal planters, with the view of improving the culture of the sugar-cane. Guano is extensively used as a manure, of which 25,707 tons were imported within the year 1856. The fertilizing power of this manure in the production of sugar is said to be almost fabulous, converting, as if by magic, sterile wastes into luxuriant plantations. The government botanical gardens at Pamplemouse are as remarkable for their varied productions as their beauty, wherein the rarest and richest plants of the East have been raised. In the vegetable and animal kingdoms there is not anything remarkable, with the exception of the fine ebony, and the dodo, a large unwieldy bird inhabiting only the Mauritius and Bourbon, but now wholly extinct.

The live stock of the island in 1854 consisted of 12,339 horses, 12,907 horned cattle, 17,076 sheep and goats. In 1854 the extent of land under each kind of crop was,—sugar-cane, 92,277 acres; maize, 6082; manioc, 5154; potatoes, 248; coffee, 125; fruits and vegetables, 8841: total in crops, 167,989 acres. Of forest land, 66,790 acres; pasture, 52,390 acres; uncultivated, 54,390. It may be observed that the staple produce of the colony is sugar. The total export of sugar in 1855 was 102,000 tons; indicating a steady and considerable annual increase. The exportation of tortoise-shell was 1648 lb.; of ebony, coffee, cloves, cotton, indigo, so small as to be scarcely worth notice. The principal imports consist of provisions and grain; cattle and rice from Madagascar and India; horses from the Cape of Good Hope; ponies from Batavia; mules from France and Spain; sheep from Bombay and the Cape of Good Hope. Earthenware, machinery, furniture, hardware, piece goods, wines, &c., are largely imported. The total estimated value of imports in 1854 was L.1,492,788; of exports for the same year, L.1,246,400. The following table exhibits a view of the import and export trade of Mauritius, as carried on with Great Britain, the British Colonies, America, and other countries, during the year 1854:—

Amount of Shipping in 1854.

	INWARDS.			OUTWARDS.		
	Ships.	Tons.	Men.	Ships.	Tons.	Men.
Great Britain.......	64	299,669	1,461	167	60,178	3,015
British Colonies ...	287	112,120	7,863	213	89,046	6,547
United States	2	1,350	39	...	...	...
Other foreign states	223	5,240	...	192	46,478	3,198
Total.........	576	418,379	9,363	572	195,702	12,760

Two lighthouses have been completed,—the main light on Flat Island, with a subsidiary one at Cannonier Point. Two mast-lights have also been erected to guide ships into the harbour. A new road has been constructed leading from Mahebourg through the valley of the Cent Gaulettes, connecting Grand Port and Moka, which will shorten the distance between the two capitals of the island 5 or 6 miles, passing by the Piton du Milieu de l'Isle, through the forest of Trois Islots and Moka, opening up large tracts of virgin land hitherto untilled and inaccessible. The main roads of the colony repaired by government are good; but the bye roads, from inefficient management, are in a very unsatisfactory condition. At present no railroads or canals have been constructed.

The government of the island, as at present constituted, is vested in a governor, aided by an executive council, of which the colonial secretary, procureur or advocate-general, and the second officer in command of Her Majesty's troops, are *ex officiis* members. There is also a legislative council, consisting of seven official and seven non-official members; the former comprising the three executive members above spoken of, and the collector of customs, auditor-general, treasurer and collector of internal revenues; the latter seven non-official members are chosen from the chief landed proprietors of the island, and submitted to Her Majesty in council for approval and confirmation. By the 8th article of the capitulation it was stipulated that the inhabitants should preserve their religion, laws, and customs; and by virtue of this provision the authority of the Code Civile, the Code de Procédeure, the Code du Commerce, and the Code d'Instruction Criminelle, except in so far as altered by the charter of justice of April 13, 1831, have since been recognised in the island. By that charter a court of appeal was reconstituted, and a supreme court of civil and criminal justice established, presided over by three justices. There is also a petty court, from which there is no appeal, for the trial of trivial crimes and offences.

The total revenue amounted in 1855 to L.348,452; the expenditure to L.317,839; leaving a surplus revenue of L.30,613. There has accumulated during the last five years an aggregate surplus revenue of L.161,915, showing that the finances of the colony are in a very satisfactory condition.

With respect to the religious and educational condition of the colony, considerable progress has been made of late years; but much remains yet to be done before it can be considered to be in a satisfactory state. There is at Port Louis, the capital of the island, a royal college, attended on an average by 284 scholars, and the fees paid by them amount to L.2587. The total cost of this establishment in 1855 was L.4129, L.1600 of which is contributed by government. The annual grant estimated for schools in 1857 is L.8788, exclusive of the royal college grant, which amounts to L.7016; the expense of sending two pupils to England, instead of one, accounting for the increase when compared with grants of former years; There are at the government schools 1860 scholars; at private schools, 2235; at the schools of the Christian Knowledge Society, 89; at the Roman Catholic schools, 908. The religious condition of the colony is not favourably reported of by the recently appointed Protestant bishop. There are but six clergymen of the Established Church, and two ministers of Protestant denominations; while the Church of Rome

Mauritius.

has provided a bishop and thirteen priests paid out of the colonial treasury. The great influx of heathen population, introduced into the colony by the employment of coolies from India, and the unequal immigration of the sexes, have tended very much to demoralize the social condition of the island. A newspaper of the Mauritius, dated Nov. 3, 1853, thus comments on this evil state of society:—"The third criminal assizes of this year commenced on the 17th of October. The calendar presented an alarming amount of crime on the part of the Indian population, and some instances of great atrocity. The most fearful social consequences must ensue upon any long-continued neglect of the moral and religious welfare of this immense branch of our population."

The island is divided into nine districts, namely, Port Louis, Pamplemouse, Flacq, Rivière du Rempart, Grand Port, Savanne, Moka, Plain de Wilhems, and Black River. The Mauritius was discovered by the Portuguese in 1507, called by them *Ilha do Cerné*, supposing it to be the *Cenne* of Ptolemy. They kept possesssion of it nearly the whole of the sixteenth century. The first who made any settlement in it were the Dutch, in the year 1598, when they changed the name from Cerné to *Mauritius*, in honour of their Prince Maurice. Being occupied in the pursuit of wealth in the East, it was abandoned by them in 1710, and was afterwards taken possession of by the French in 1721, who called it *Ile de France.* The first regular settlement took place in 1735 under Monsieur de la Bourdonnais, who introduced manufactures and the culture of the sugar cane, cotton, and indigo, and engaged himself in raising public edifices, making roads, and clearing the forest with which the island, when first visited, was covered. Upwards of half a century elapsed before the French duly appreciated the value of their new acquisition, the foundation of its prosperity having been laid by the governor above named, who fixed a port on the N.W. of the island as the seat of its present capital, Port Louis. He was succeeded by Monsieur de Poivre, who, notwithstanding the jealousy of the Dutch, brought from the distant isles in the Eastern Archipelago, and introduced into the colony, the clove, nutmeg, and various other spice trees. The Isle of France was for a long time during the war a source of great mischief to our merchant vessels and Indiamen. The position of the island in the eastern seas, and the facility with which sorties might be made from it upon our traders by French men-of-war and privateers, determined the British government upon an expedition for its capture, which was effected in 1810. At the peace in 1814 the possession of the island was ratified, since which the Mauritius has continued annexed to the British Empire.

The population of the Mauritius and its various dependencies, consisting of different races and every conceivable form of admixture springing from these, amounted, by the census taken in 1851, to 120,331 males, 61,482 females; of whom, in 1854, 60,350 were employed in agriculture, 5322 in manufactures, and 5419 in commerce. The number of births in 1854 was 5683; deaths, 14,398; marriages, 610.

The island of Rodrigue, the Seychelles Islands, Diego Garcia, and others belong to Mauritius. Rodrigue is situated about 300 miles to the eastward of Mauritius, in S. Lat. 19. 13. It is 26 miles in length by 12 in breadth, and consists of a succession of verdant hills. Although the valleys are almost full of rocks and stones, there still remains a considerable portion of fertile soil, which is cultivated by colonists from the Mauritius. The vegetation is luxuriant, the climate salubrious, and the water clear. There is abundance of fish around the island, but some of them are poisonous at certain seasons, when feeding on the coral plant. The Seychelles or Mahé Islands are situated between the parallels of S. Lat. 4. and 5. There is nothing interesting regarding their history. The lepers from the Mauritius are sent to Mahé. When Mauritius capitulated to Britain they were taken possession of as a dependency of that colony, which keeps there a civil commissioner, assisted in his duties by subordinates. There is a petty civil and criminal court held for trial of causes and offences. The social condition is not favourably reported of by the present commissioner in his report to the governor of the Mauritius. This dependency is a great expense to the colony of Mauritius.

Mauro.

The names of the principal islands, with the number of acres in each, are as under:—

Names.	Acres.	Names.	Acres.
Mahé	30,000	Marianne	250
Praslin	8,000	Conception	120
Silhouette	5,700	Felicity	800
La Digue	2,000	North Island	500
Curieuse	1,000	Denis	200
St Anne	500	Vache	200
Cerf	400	Aride	150
Frigate	300		

Total number of acres, 50,120.

There are a number of other smaller islands, all resting on an extensive bank of sand and coral, which also surrounds them to a great extent. Mahé, the principal island and seat of government, is 16 miles in length, and from 3 to 5 in breadth, with a very steep and rugged granite mountain running through the centre. The vegetation on this, as well as on many others of the group, is extremely luxuriant; and amongst their productions are various spices, such as the cinnamon, clove, &c. The town of Mahé is situated on the N. side of the island; its population has varied very little for the last thirty years, and may be estimated at about 7000. These dependencies are visited by whaling vessels for water, hogs, goats, &c., with which some of the uninhabited islands abound. The most remarkable vegetable production is the *coco de mer*, so called because the nuts were found on the coast of Malabar long before the place of their growth was known. 50,000 have last year been planted by an enterprising Frenchman; and there is little doubt that, if labour was more abundant, and means of communication were constructed, the Seychelles might be made a valuable dependency to the Mauritius. Tortoise-shell is exported from these islands. A gale of wind is unknown in these tranquil seas; but the ocean breezes are constant, thus tempering the rays of a vertical sun. Diego Garcia is situated about four degrees further E., and is one of those numerous coral islands with which these seas abound. It contains abundance of turtle; and has a few residents from the Mauritius. (H. B. J.)

MAURO, Fra, the most celebrated cosmographer of his time, was a friar of the Order of Camaldoles, in the monastery of St Michele di Murano, near Venice. He flourished in the fifteenth century; but the date of his birth and death are alike unknown. The fame he had acquired in the physical and mathematical sciences caused him to be chosen, in 1444, member of a commission of fifteen Venetian patricians, who were intrusted by government to regulate the course of the River Brenta, and to direct the work relating to the lagunes. Between 1457 and 1459 he made his celebrated map of the world, which has been so frequently copied, and which may still be seen in his monastery near Venice. In that singular production the progress of geographical science is marked with the utmost precision. In addition to the travels of Marco Polo, Fra Mauro marked down Cape Verde, Cape Roxo, the Gulf of Guinea, and all he could learn from the navigators of that day, who have left no written account of their voyages. Thus, Darfur, unknown to Europe till the time of Bruce, is mentioned under the name of *Dafur.* He also took notice of what was known to the Arabs, who at that time had pushed their discoveries on the coast of Africa as far as Sofala, and even visited Madagascar.

The highest glory of Fra Mauro, however, was the efficient aid he rendered to the two greatest expeditions of modern times, which resulted in the discovery of the Cape of Good Hope and the continent of America. His map is the first in which the E. and W. coasts of Africa are made to approach each other till they almost form a point, clearly indicating the passage round the Cape. There also may be seen beyond the Azores (faintly indicated and erroneously marked, it is true) several islands named Antilles and Brazil; and it is precisely by these names that Columbus and Vespucci distinguished the land they first discovered; thus favouring the conclusion that it was on the faith of Fra Mauro's map of the world that they were incited to their bold and immortal discoveries. Alphonso V. of Portugal requested Fra Mauro to draw a planisphere to serve as a guide to the intrepid Portuguese mariners, who had already endeavoured to find a passage to the East Indies; and we gather from a writer of the time (Francis Alvarez), and from the account-book of the monastery of S. Michele, that a copy of the map still existing there was given to the captain of two caravels sent out on a voyage of discovery in 1487, and paid for by King Alphonso. The Venetian Republic ordered a medal to be struck, on which may be seen the likeness of Mauro surrounded by the inscription, "*Frater Maurus S. Michaelis Moranensis de Venetiis Ordinis Camaldonensis Cosmographus incomparabilis.*" The last and most complete account of the planisphere is that by the Cardinal Placido Zurla: *Il Mappamondo di Fra Mauro de critto ed illustrato*, Venezia, 1806. (E. F.)

MAUROLYCO, or **Maurolycus, Francis**, the greatest geometrician of his age, was born at Messina in September 1494. After he had completed the course of study requisite for entering the church, he resolved to devote the rest of his life to mathematics. His father is said to have been his only instructor in that science; yet in a short time Maurolyco was selected to teach geometry to the eldest son of the viceroy, John de Vega. At the court of that prince he formed a friendship with Cardinal Alexander Farnese, and the Marquis Geraci. The latter conferred upon him the rich abbey of Santa Maria del Parto, and employed him to teach mathematics in the college of Messina. Thither geometricians from all parts of Italy were wont to resort for the purpose of consulting Maurolyco. After the death of his patron Geraci, Maurolyco retired to the country. He died in July 1575. His principal works are,—An edition of the *Spherics* of Theodosius, folio, 1558; *Martyrologium*, 4to, 1566; *Opuscula Mathematica*, 4to, 1575; *Arithmeticorum libri duo*, 8vo, 1575; *Euclidis Phænomena*, 4to, 1591; *Emendatio et Restitutio Conicorum Appollonii Pergæi*, folio, 1654; and *Archimedis Monumenta Omnia*, folio, 1685. (For an account of his services to mathematics, see *Dissertation Fourth*.)

MAURY, Jean Siffrein, *Cardinal*, the son of a poor shoemaker, was born at Vauréas, in the department of Vaucluse, in 1746. After receiving his education at the seminaries of St Charles and St Garde in Avignon, he left his home at a very early age, and arrived in Paris a poor, friendless adventurer. A funeral oration on the Dauphin introduced him to the public in 1766, and its success led him to take orders, and to devote himself with ardour to the study of pulpit eloquence. Thus obtaining a fair scope, his oratorical powers raised him in quick succession to several appointments. For a eulogy on Fenelon, written in 1770, he was appointed vicar-general of the Bishop of Lombez; a panegyric on St Louis, pronounced before the French Academy in 1772, gained for him the appointment to the abbey of Frenade; and on account of a eulogy on St Augustine, delivered before the assembled clergy in 1775, he was nominated preacher to the court. He now became intimate with men of rank and genius, and, through their influence, was elected a member of the French Academy in 1785. In the following year the valuable priory of Lihons was bequeathed to him by his friend the Abbé de Boismont. During the troublous days of 1789 Maury's ardent temperament could not brook inactivity. Accordingly, he appeared in the assembly of the states-general as deputy of the clergy of the bailiwick of Péronne. At first he was content to be a silent spectator of the confused wranglings of his associates. In the month of September, however, when the *veto* of the king came to be discussed, Maury threw aside his taciturnity, and stood forth as a bold defendant of monarchy. Recognised in a short time as one of the champions of the aristocratic party, he often entered the lists against Mirabeau, and his cool courage and ready eloquence made him almost a match for that redoubtable orator. He showed the same self-possessed heroism in the troubled streets of Paris; and never moved abroad without two loaded pistols. On the 9th of November 1789 he threw the Assembly into violent commotion by his bold and persistent opposition to the conversion of church property into national domains. Coming out of the hall on the same day among the infuriated mob, he was received with a universal shout, "To the lamp-iron with Abbé Maury!" "Well," replied the imperturbable abbé, "here he is; when you hang him on the lamp-iron, will you see better there?" and by this ready joke he threw the multitude into convulsions of laughter, and saved his own life. At the dissolution of the Assembly in 1792 he left France. His fame had gone before him; and after meeting the most hearty welcome at Chambery, Brussels, Lièges, and Coblentz, he was summoned to Rome by Pius VI. He was received with great distinction; was nominated archbishop of Nicæa *in partibus*; and was despatched as papal nuncio to the diet assembled at Frankfort for the coronation of Francis II. In 1794 he was appointed cardinal, and bishop of the united see of Montefiascone and Corneto. The terrors, however, which had driven him from his native country followed him to his place of refuge. The armies of republican France entered Rome in 1798, and Cardinal Maury was obliged to skulk for some time in Tuscany, and afterwards to flee to Venice under the guise of a carrier. He then retired to Russia, but returned to Rome in 1799 in the suite of Louis XVIII. After this period, a growing desire to visit Paris, the scene of his early greatness, seems to have gradually extinguished his zeal for the Bourbons. Accordingly, he followed the example of the Holy See by recognising in 1804 the government of Napoleon. In 1806 he returned to the French capital by permission, but found that his political apostacy had excluded him from those brilliant circles in which he was wont to move. Warmly befriended, however, by Bonaparte, Maury was nominated a French cardinal, and appointed chaplain to King Jerome. His elevation to the archbishopric of Paris followed in 1810, and subjected him to the heavy displeasure of Pope Pius VII.; but Maury silently refused to quit his see at the sovereign pontiff's command, and continued to show for his new master a devotion that verged upon slavishness. At the restoration of 1814 he was ordered to evacuate his archiepiscopal chair. Slowly and unwillingly he bent his steps toward Rome, and on his arrival in that city he was thrown into the castle of St Angelo. His liberation was purchased, after the lapse of a year, by his resignation of the see of Montefiascone and by other humiliations. He lived in retirement till his death in May 1817. Maury's principal work, *Essais sur l'Eloquence de la Chaire*, was translated into English by John Neale Lake, 8vo, London, 1793. After its author's death it was reprinted in the original by Louis Siffrein Maury, nephew of the abbé. The same editor published Maury's select works, with a Life, in 5 vols. 8vo, Paris, 1827.

MAUSOLEUM, a term applied in modern times to any sepulchral edifice erected for the reception of a monument, but which originally signified the sepulchre of Mausolus, a magnificent structure erected to the King of Caria by his queen Artemesia, at Halicarnassus, B.C. 353. The most eminent architects and artists of the time, of the Ionian and Attic schools, were employed by this pious queen to raise this splendid monument to the memory of her deceased husband, the dynast of Caria. Phileus and Satyrus were intrusted with the architecture; while the great Attic artists, Scopas, Bryaxis, Leochares, and Timotheus or Praxiteles, were employed on the sculptural decorations. These sculptors worked each at a face of the building, emulous of each other, and passionately devoted to their splendid undertaking. The queen died, but the artists continued their labours, and did not withdraw their hands until they had rendered it one of the seven wonders of the world.

Pliny's description of this structure (*Hist. Nat.* xxxvi. 5), though the most complete which we possess, is nevertheless in many respects unsatisfactory. This writer informs us that the building was an oblong quadrangular *cella*, 63 feet from N. to S., 411 feet in circumference, and 37½ feet in height; decorated with a peristyle of 36 columns, and carried up into a pyramid, surmounted at the apex by a marble quadriga, executed by Phileus, one of the architects. The entire edifice has a total height, from base to summit, of 140 feet. The discrepancy between the total and the partial heights can only be got over on the assumption that the peristyle was elevated on a basement; and the apparent discrepancy between the lengths of the faces and the total circuit, can only be explained by supposing that the structure stood upon an elevated inclosure, with a perimeter of 440 feet, the length given by the Bamberg MS. Direct measurement of it is impossible, for unfortunately this magnificent edifice no longer exists; the very site of it is doubtful, and the only remnant of its former splendour is to be found in the *Budrum Marbles* in the British Museum. These precious fragments of the handiwork of those devoted artists were collected in 1846 around the walls of *Budrum*, now occupying the site of the ancient Halicarnassus. Many of the slabs and columns of the Mausoleum were, in the fifteenth century, worked into the fortifications of this modern city; yet recent travellers cherish the hope that, from the materials still in existence, the plan of this famous sepulchral edifice may yet be restored. (For an examination of the proposed restoration, see a very able essay, with illustrations, *On the Sculptures from the Mausoleum at Halicarnassus*, by Charles Newton, in the Classical Museum for July 1847.)

The Roman mausolea were for the most part built in a series of circular terraces, after the manner of the *rogus*. Those of Augustus and Hadrian were the most celebrated; the latter of which has been converted into the Castello di St Angelo, the fortress of modern Rome, while the former has been reduced almost to a heap of ruins.

MAXENTIUS, Marcus Aurelius Valerius, a Roman emperor, was raised to the throne A.D. 306, and was defeated by Constantine and drowned in the Tiber A.D. 312. (See Roman History.)

MAXIMIANUS, Galerius Valerius, a Roman emperor, was the son of a shepherd in Dacia, was raised to the throne along with Constantius, A.D. 305, and was cut off by a loathsome disease A.D. 311. (See Roman History.)

Maximianus, *Marcus Aurelius Valerius*, a Roman emperor, was born in Pannonia of poor parents, divided the empire with Diocletian A.D. 286, abdicated the throne A.D. 305, was restored by his son Maxentius A.D. 306, and strangled himself A.D. 310. (See Roman History.)

MAXIMINUS, Caius Julius Verus, a Roman emperor, was originally a Thracian shepherd, was invested with the purple by the mutinous soldiers A.D. 235, and was murdered by his insurgent army A.D. 238. (See Roman History.)

Maximinus, *Galerius Valerius*, a Roman emperor, was originally an Illyrian shepherd, shared the empire with Licinius A.D. 311, and died A.D. 314. (See Roman History.)

MAXIMUS, the Confessor or Monk, a famous ecclesiastic, was born of noble parentage at Constantinople, about A.D. 580. He was educated with great care, and was early distinguished both for talents and piety. After he had attained his prime, he was reluctantly withdrawn from his favourite study of philosophy to become secretary to the Emperor Heraclius. It is also said that his royal patron wished him to write the civil history of that age. But when the emperor, about the middle of his reign, aimed at re-admitting the Monothelites within the church, Maximus boldly protested against such sinful policy by forthwith vacating his situation. This decisive step was probably accelerated by a lingering desire for the life of a recluse; for he immediately crossed to Asia, and entered a monastery at Chrysopolis (*Scutari* or *Iskudar*). There his extreme asceticism speedily raised him to the rank of abbot. At a later date Maximus, now well advanced in years, is found in the Roman province of Africa, arguing face to face with the Monothelites, writing letters and tracts to refute them, and summoning to his aid, in this determined warfare, all available power, both civil and ecclesiastic. He then, in 649, bent his steps towards Rome to fan the orthodox zeal of the new pope, Martin I. But Maximus, as the head of the Dyothelitic party in the church, and therefore the chief opposer of the imperial decrees in favour of Monothelitism, had become obnoxious to the Emperor Constans II. He was accordingly apprehended in 653, carried to Constantinople, and thrown into prison. On the day of trial the far-famed piety of the aged abbot secured the respect of his judges. He was merely asked to sign a formulary which had been drawn up for the occasion, and which might have been shown, by an ingenious interpretation, to include his doctrinal tenets. But Maximus refused to conceal the very smallest of his honest convictions under the guise of ambiguous expression. Persuasions, threats, and flatteries were all tried in vain; and he was therefore sentenced to imprisonment in the castle of Bizya (*Viza*) in Thrace. There the most cruel and most ignominious treatment could not alter his opinions, and at last his constancy outlived the patience of his enemies. In 662 he was dragged again to Constantinople, where, after being publicly scourged, he had his right hand chopped off and his tongue cut out. The old man was then banished to the Caucasus to die of his manifold sufferings.

The writings of Maximus display acute and profound thought, expressed in language often obscure and inelegant. A collection of his works, published by Combéfis in 2 vols. folio, Paris 1675, consists of letters, answers to theological questions, controversial tracts, and moral and monastic pieces. (For a list of his numerous productions, see Smith's *Dictionary of Greek and Roman Biography*.)

Maximus, *Magnus Clemens*, a Roman emperor, was a native of Spain, was invested with the purple A.D. 383, and was beheaded by Theodosius A.D. 388. (See Roman History.)

Maximus, *Petronius*, a Roman emperor, descended from the nobility of Rome, was born about A.D. 388, was proclaimed emperor A.D. 455, and was assassinated in the same year. (See Roman History.)

Maximus, *Tyrannus*, a Roman emperor, was raised to the supreme power by Gerontius A.D. 408, was forced to abdicate by Constantine A.D. 411, and was put to death A.D. 422. (See Roman History.)

MAXWELLTOWN, a borough of barony in Scotland, county of Kirkcudbright, is situated on the Nith, opposite Dumfries, with which it is connected by two bridges, and of which it was formerly a suburb, known by the name of Bridgend. It contains a church, several schools, a town-house, and several iron-works, rope-works, mills, &c. The borough is governed by a provost and two baillies. Pop. (1851) 3820.

MAY, the fifth month of our modern year, was the third of the old Roman calendar. The name is of doubtful origin. Ovid (*Fasti*, v. 483–90) suggests the three derivations of *majestas*, *majores* (the *patres* of the old Roman city), and *Maia*, the mother of Mercury, to whom the Romans were accustomed to sacrifice on the first day of the month. Others, again, have been of opinion that its origin is Teutonic, being derived from some obsolete word signifying youthful beauty and loveliness. The Saxons, after the Romans, called it *Maius monath*. It was considered unlucky among the Romans to contract marriages during this month, on account of the celebration of the Lemuria,—a superstition of which traces are still to be found among ourselves.

MAY-DAY, the name given to the first of the month in this country, when, according to ancient custom, all ranks of the people rose at early dawn and went out *a-Maying* to welcome the first return of the spring. The rites and festivities peculiar to this occasion can be traced back, according to some, to the heathen observances with which the Latin goddess Flora was wont to be honoured. At all events, some of the English ceremonies of May-day are as old as the Druids, who were accustomed to light large fires on the heights on May-eve, to herald with devout joy the coming spring. In the time of Bourne (*Vulg. Antiq.*) the juvenile part of both sexes in the villages of the north of England were wont to rise shortly after midnight on May morning, for according to Chaucer, "May wole have no sloggardye a night," and proceed, accompanied by music and horn-blowing, to some neighbouring wood, where, after breaking down branches from the trees, and adorning themselves with nosegays and garlands, they returned home at sunrise and decorated their doors and windows with the flowery spoil. Nor was this custom limited to the vulgar: even royalty itself occasionally condescended to share in this diversion. Chaucer, in addition to his beautiful allusion to the May-day customs in the *Knightes Tale*, says in his *Court of Love*, that early on May morning—

> "Fourth goeth al the court, both moste and leste,
> To feche the floures freshe, and braunch and blome."

And Hall, in his *Chronicle*, gives an account of Henry VIII.'s riding a-Maying with Queen Katherine from Greenwich to the high ground of Shooter's Hill, accompanied by many lords and ladies, who "went with their bows and arrows shooting to the wood." Shakspeare alludes also to the custom when he says, in his *Henry VIII.* (act v., scene 3), that it was impossible to make the people sleep on May morning; and when, in his *Midsummer Night's Dream* (act iv., scene 1), he talks of doing "observance for a morn of May." May-dew was also believed to possess a singular virtue. Samuel Pepys, in his *Diary*, informs us that his wife had gone down to Woolwich "to take a little ayre and gather May dew," in consequence of being told by a certain lady that "May-dew was the only thing in the world to wash her face with." Other minor observances on May-day were those of dancing round the May-pole decked with garlands, still known in England; the Jack-in-the-Green of the chimney-sweepers, who still perambulate and dance in the streets of London (see the *Times* of May 2, 1844; also *Literary Gazette*, May 1847); and the custom, now half a century old, of the London milkmaids, adorned with a garland of plate (hired for the occasion), and a profusion of flowers, dancing before the doors of their customers to the music of a fiddle. Old Stow, in his *Survay of London* (1603) sums up a number of the festive details of May-day in the following sentence:—"I find also that, in the moneth of May, the citizens of London, of al estates, lightly in every parish, or sometimes two or three parishes joyning togither, had their severall Mayings, and did fetch in May-poles, with diverse warlike shewes, with good archers, morice-dancers, and other devices, for pastime al the day long, and towards the evening they had stage-players, and bone-fiers in the streetes." These May customs were not, however, wholly limited to England. (But for further information, see Brand's *Popular Antiquities*, vol. i., p. 212; also Grimm's *Deutsche Mythologie*, p. 448, &c.)

MAY, ISLE OF, a small island of Scotland, county of Fife, in the Firth of Forth, 6 miles S.E. of Crail. It is about a mile in length, and nearly a mile in breadth, consisting of slaty rock. It affords pasturage for sheep and cattle, and is frequented by great numbers of sea-birds. There is a lighthouse on the island with a fine dioptric light, 240 feet high, and visible from a distance of 21 miles. The cliffs are for the most part steep and perpendicular, rising in some places to the height of 160 feet. Pop. (1851) 18.

MAY, THOMAS, an English historian and poet, was born in 1595 of an ancient family in Sussex. He was educated at Cambridge, and, after taking the degree of B.A., he repaired to London, and became a member of Gray's Inn. In the course of time his talents found favour at court, and several of his poems were published by the special command of Charles I. He was thus led to expect the laurel on the death of Ben Jonson in 1637. But Sir William Davenant was preferred; and May abandoned the court in a pet, and was ever afterwards a republican. During the civil war he became secretary to the Parliament, and was employed to write its *History*. This work, published originally in Latin, was translated into English in 1650. It is tame and inelegant, yet, on the whole, it is truthful in its facts, and unbiassed in its judgments. On the night of the 12th of November 1650, May retired to bed in good health, "after his chearful bottle as usual," and died in his sleep before morning. His remains were laid in Westminster Abbey; but soon after the Restoration they were disinterred, and thrown into a pit in the adjoining churchyard of St Margaret's. A monument that had been erected over his grave was also demolished.

May is the author of five plays, and of two poems on the reigns of Henry II. and Edward III. respectively. He translated into English verse *Selected Epigrams of Martial*, Virgil's *Georgics*, and Lucan's *Pharsalia*. To the last of these he wrote a continuation both in English and Latin. His *History of the Parliament* was edited by Baron Masères, 4to, 1812.

MAYBOLE, a borough of barony, and market-town of Scotland, county of Ayr, is pleasantly situated on a hill 5 miles from the sea, and 9 S. of Ayr. The town is well built, especially the ancient part, owing to its having been formerly the residence of many of the aristocracy, as the capital of the district of Carrick. The town possesses several specimens of baronial residences, among which the most remarkable is the castle, which was formerly occupied by the Earls of Cassilis, and now by a factor of the Marquis of Ailsa. The parish church is a large but clumsy building; and there are also Free, United Presbyterian, and Wesleyan churches. Maybole has besides several schools, libraries, a savings-bank, and other institutions. The inhabitants are employed to a considerable extent in handloom weaving. West of the town stand the ruins of Crossraguel Abbey, one of the abbots of which, Quintin Kennedy, held a disputation with John Knox in Maybole in 1561. This discussion lasted for three days, and ended unsatisfactorily, both disputants claiming the victory. The house where the disputation took place is now the Red Lion Inn. Pop. (1851) 3862.

MAYEN, a walled town in Rhenish Prussia, capital of a circle of the same name, in the government of Coblentz, is situated on the Nette, 17 miles W. of Coblentz. It has manufactures of woollen cloth, paper, and earthenware. Pop. 5288.

MAYENCE (German *Mainz*, ancient *Moguntiacum*), a town of Germany, capital of the province of Rhenish Hesse, in the grand duchy of Hesse-Darmstadt, is beautifully situated on a sloping hill on the left bank of the Rhine, not far from its confluence with the Main, 20 miles W.S.W. of Frankfort. The town is built in an irregular and old-fashioned style; most of the streets are narrow and gloomy, the houses are in general high, and the squares have a fine and imposing appearance. Outside the town there are large public gardens, called Neue Anlage, which form a fashionable and much frequented promenade, and command a fine view of the town and surrounding country. The cathedral, which is of great antiquity, and has been destroyed by fire not less than six times, exhibits specimens of the styles of several centuries; and, though interesting as an illustration of the history of art, it does not possess much architectural beauty, and is not seen to advantage, owing to its being blocked up with mean houses. It has six towers, one of which is above 200 feet in height, while another, of 70 feet, is surmounted by a cupola. The building contains many monuments of much interest and of great antiquity; a handsome pulpit, 14 altars, and 20 chapels. There is also the church of St Ignatius, built in a beautiful style, and adorned with fine pictures by Zick. The other important buildings in Mayence are,—the church of St Peter, with two towers and a fine peal of bells; that of St Stephen, whose tower commands a fine view; the ancient palace of the electors, now used as the merchants' hall; the grand ducal palace, now occupied by the governor, and formerly the palace of the Teutonic order; the library, containing 100,000 volumes; and the theatre. There was formerly a college here; but its place is now supplied by a gymnasium. Opposite the theatre stands a bronze statue by Thorwaldsen of Gutenberg, a native of this town, who is one of the claimants of the honour of the invention of printing, as he was the first to use metal types. In the citadel stands the Eichelstein, supposed to be the monument mentioned by ancient authors as erected here in memory of Drusus, brother of the emperor Tiberius, and father of Germanicus. The town of Mayence is strongly fortified, and is indeed one of the strongest places in Europe, serving as a defence for Germany on the side of France. On the other side of the Rhine stands the suburb of Castel, which is joined to the town by a bridge of boats, and also fortified; and a small island in the river, called Petersan, is no less securely defended. Mayence has towards the country 4 gates, with double drawbridges, while the whole extent of the defences is so great as to require a garrison of 30,000 men to man them fully. The fortress belongs to the German Confederation; and is garrisoned in time of peace by 6000 Austrians, Prussians, and Hessians, under an Austrian and a Prussian general alternately, each of whom retains the command for five years. There is believed to have been a town of the Mediomatrici on the site of the modern Mayence, before the foundation of a fortress here by Drusus, in the year 13 B.C. The town does not, however, seem to have been of any great importance during the continuance of the Roman empire; and was destroyed by the Vandals in 406. After lying in ruins for some centuries, Mayence was restored by Charlemagne, and attained to great prosperity after the time of Bonifacius, bishop of Mayence. In the middle ages this was the first ecclesiastical city of Germany; and the archbishop was one of the electors, and premier prince of the German empire. In 1798 Mayence having fallen into the hands of the French, was made the capital of the department of Mont Tonnère; but in 1816 it was given to the Grand Duke of Hesse. Pop. 31,365.

MAYENNE, a department of France, bounded on the N. by those of Manche and Orne, E. by that of Sarthe, S. by those of Maine-et-Loire and Loire Inferieure, and W. by that of Ille-et-Vilaine. It is 55 miles in length by about 30 in breadth. The department is bounded by low ranges of hills on the N., E., and W., and has a general slope towards the S. It consists of gently undulating plains without any marked elevation or depression. The principal river, the Mayenne, from which it derives its name, traverses it from N. to S., dividing it into two nearly equal parts. The department contains also several small lakes. The rocks of Mayenne belong almost entirely to the earliest geological epochs, and contain a considerable amount of mineral resources. Iron, coal, limestone, marble, slate, granite, building-stone, &c. are obtained in the department. The soil is not very fertile, except in the southern parts, where all sorts of corn are grown, while in the other districts the produce of the soil is not sufficient to supply the wants of the inhabitants. Of the entire area of the department, 885,000 acres are occupied with arable land, 172,500 are meadow land, and 65,000 wood. Notwithstanding the small extent of the meadow-land, a great number of live stock is reared on the heaths and fallow land of the department; and the cattle are of good breed, and highly prized. It has been calculated that there are in Mayenne 50,000 horses, 180,000 head of large cattle, 140,000 sheep, 50,000 pigs, &c. The department is very much broken up into small farms, some of them so small as to be cultivated with the spade; and the population live in their own separate farm-houses, instead of congregating in towns and villages. The effect of this on the character of the people may be seen in the blunt honesty and obstinate independence by which the peasant of Mayenne is characterized; but they are also both unable and unwilling to engage in any enterprize for improving their ground, by which their condition might be bettered. The fields are in general surrounded by hedges and rows of trees; and this gives the country, when seen from a distance, the aspect of a vast forest. The principal manufacture carried on in the department is that of cloth, especially table linen and sailcloth; and there are also several forges and iron-works. The trade consists principally in iron. Mayenne contains several ancient Roman and Druidical remains; and at Jublains there have been preserved the remains of one of the strongest Roman forts to be seen in France. In the middle ages this department was the scene of many bloody encounters between the English and the French; and in the Vendean war a great victory was gained here by the Royalists under Larochejacquelin, in 1793, over the Republican forces. The capital of the department is Laval; and it is divided into three arrondissements as follows:—

	Cantons.	Communes.	Population.
Laval	9	92	130,523
Château-Gonthier	6	72	78,862
Mayenne	12	110	165,181
Total	27	274	374,566

MAYENNE, a town of France, capital of the arrondissement of the same name, in the above department, is irregularly built on both sides of the River Mayenne, 18 miles N. by E. from Laval. The streets are extremely steep, and the houses quaint and old-fashioned. The principal building is the old castle on the right bank of the river. Mayenne has some manufactures, especially of linen fabrics; and there are also cotton mills, bleachfields, and dye-works. The trade consists in the productions of its manufacture and agriculture, especially grain and cattle. The town was formerly strongly fortified, and resisted for three months a siege by the English, under the Earl of Salisbury, to whom it surrendered in 1424. In 1544 it was made a duchy by Charles IX., and gave the title of Duke of Mayenne to

Charles of Lorraine, afterwards famous as the head of the League. Pop. (1851) 9588.

Mayenne (anciently *Meduana*), a river of France, rises in the hills of the department of Orne, near Pré-en-Pail, and flows westward till its confluence with the Varenne. It then takes a southerly direction, and empties itself into the Loire. In the upper part of its course it is inclosed between rocky banks; but from Laval, where it becomes navigable, it flows southward with a broad and deep current through extensive and beautiful meadow-lands. The principal towns on its banks are Mayenne, Laval, Entrames, and Château-Gonthier. It receives, from the right, the Ernée and the Oudon, and from the left the Aron and the Jouanne. Its total length is 125 miles, and it is navigable for 55 miles.

MAYER, Tobias, one of the greatest astronomers of the eighteenth century, was the son of a civil engineer, and was born at Marbach in Würtemberg, on the 17th February 1723. The elements of mathematics he received from his father, but the rest of his knowledge in that science was self-acquired. At an early age he was left an orphan, and was forced to earn a livelihood by giving mathematical lessons. His first publications, *A Treatise on Curves for the Construction of Geometrical Problems*, and *A Mathematical Atlas*, appeared in 1745. In the following year he contributed to the establishment of the Cosmographical Society of Nuremberg. He was appointed director of the observatory of Göttingen in 1751; and there, in the midst of the turmoil of the Seven Years' War, and in the vicinity of powder magazines, he prosecuted his studies with untiring devotion. The *Lunar Tables*, the chief result of his labour, appeared in the "Acts of the Academy of Göttingen" in 1755. About this time also, Mayer discovered the principle of the *Repeating Circle.* His extreme application, however, had caused a disease which was gradually undermining his health. He died on the 20th February 1762, at the age of thirty-nine. Over his grave at Göttingen, a monument was erected in 1801. (For an account of Mayer's Lunar Tables, and his invention of the Repeating Circle, see *Dissertation Fifth*, § 2, pp. 749, 781.)

An edition of his works had been promised, but of these only one volume appeared under the care of Lichtenberg, his friend and associate. It contains, 1. A method for determining more exactly the variations of the thermometer, with a formula for calculating the mean degree of heat in every latitude, and the seasons of the year in which occur the greatest heat and the greatest cold. 2. A memoir on the observations which he made with his mural arc of six feet, and the verifications to which he subjected that instrument. 3. An easy method for calculating eclipses of the sun, being at bottom the method of Kepler, which Lacaille also reproduced in his *Leçons d'Astronomie.* 4. A memoir on the affinity of the colours, in which he recognised only three primary colours, all the rest being obtained by different combinations of these. 5. His new catalogue of the stars, the work of two years, during which he experienced several interruptions, especially when the old tower on which his observatory stood was converted by the French into a powder magazine. 6. A memoir, followed by a catalogue of eighty stars, to which he assigned a peculiar motion, independently of the general motion of precession. His éloge, pronounced at the academy by Kaestner (Göttingen, 1762, in 4to), is followed by a list of his works, which we shall here subjoin. 1. Description of a new Globe of the Moon; 2. Terrestrial Refractions; 3. Geographical Charts, including a Critical Chart of Germany, and a Map of Switzerland; 4. Description of a new Micrometer; 5. Observations on the Eclipse of the Sun in 1748; 6. Conjunctions of the Moon and the Stars observed in 1747 and 1748; 7. Proofs that the Moon has no atmosphere; 8. Motion of the Earth explained by a change in the direction of gravity; 9. Latitude of Nuremberg, and other Astronomical Observations; 10. Memoir on the Parallax of the Moon and its distance from the Earth, deduced from the length of a pendulum beating seconds; 11. On the Transmutation of rectilineal figures into triangles; 12. Invention of a species of Painting of which the products may be multiplied; 13. Inclinations and Declinations of the Magnetic Needle, deduced from theory; 14. Inequalities of Jupiter.

MAYNOOTH, a town of Ireland, in the province of Leinster, and county of Kildare, is situated on the Royal Canal and Rye Water, 15 miles W. by N. of Dublin. The town consists of one street, extending from the entrance to Carston, the seat of the Duke of Leinster, on the E., to the Roman Catholic college on the W. There are in Maynooth a parish church, a Roman Catholic chapel and nunnery, a court-house, schools, and a dispensary. The college of Maynooth is a plain brick building, in the form of a quadrangle, with a frontage of 400 feet in length. The grounds belonging to it occupy an area of 54 acres. (For further particulars respecting this institution, see Ireland.) Near the college stand the ruins of Maynooth Castle, built in 1426, and formerly the residence of the Fitzgerald family. Pop. (1851) 2201.

MAYO, a maritime county in the province of Connaught in Ireland, is bounded on the N. and W. by the Atlantic Ocean, on the E. by the counties of Sligo and Roscommon, and on the S. by that of Galway. According to the Ordnance Survey, it comprises an area of 2131 square miles, or 1,363,882 acres; of which 497,587 only are arable, 800,111 uncultivated, 8360 in plantation, 848 in towns, and 56,976 are under water. Although this county contains a greater extent of unimproved waste lands than any other in Ireland, a large portion, more particularly in the baronies of Erris and Burrishoole on the western coast, present great facilities for reclamation and cultivation. Of the great extent of bog and moor land situated in the barony of Tyrawley, W. of Ballina, much might be improved for cultivation; but owing to the scarcity of manure, so easily obtainable on the coast of Erris and Burrishoole, not with equal advantage as in those baronies. Of the entire 800,000 acres of uncultivated land, it is estimated that 170,000 might be improved for cultivation, 300,000 might be drained for pasture, and about 330,000 must be considered unimprovable.

According to Ptolemy, the earliest inhabitants of this region were the Nagnatæ. It was afterwards divided into districts, distinguished by the names of the chieftains or principal settlers; of whom those of greatest note were M'William Oughter, O'Maley, M'Jordan, O'Dondey, and O'M'Philben, to which were subsequently added the Nangles, the Dillons, and others of British descent.

The whole of Connaught, except Roscommon, was considered as one county by the English, until the beginning of the reign of Elizabeth, by whom it was made shire ground, and this county then took its name from the monastery of Mayo or Mageo in it. It is now divided into the nine baronies of Burrishoole, Carra, Clanmorris, Costello, Erris, Gallen, Kilmaine, Murrisk, and Tyrawley. The county is in the dioceses of Tuam, Killala, and Achonry.

The appearance of the country varies very much. In the eastern parts it contains extensive plains capable of cultivation, and rising occasionally into hills of moderate height; the western part is wholly mountainous, and covered in most parts with bog, except in some places near the sea, where the soil, unless when covered with drifted sand, is sufficiently fertile. In some parts of the flat country, near Lough Mask, the ground appears like one plain of greystone, which, on a closer examination, is found to consist of parallel layers of rock rising edgeways out of the ground, and having the intervening furrows filled with a productive soil that throws up an herbage peculiarly grateful to sheep. Among the principal mountains, Muilrea (2688 feet high, the most elevated point in Connaught), is conspicuous. This fine mountain, which, with Bengorm (2286 feet), forms the northern or Mayo side of Killary Harbour, has its summit level about a mile from the sea, towards which it presents a grand and imposing aspect. Croagh-Patrick (2530 feet high) stands on the southern shore of Clew Bay. This mountain is amongst the most celebrated in Ireland, not only for its height and the majestic outline it presents from the various positions whence it can be viewed, but from the tradition that St Patrick chose its summit as the place to stand on when he drove all the venomous reptiles of the island into the sea. Nephin, 2640 feet high, to the W. of Lough Conn, is of a conical form, with rugged and steep sides, quite isolated by its great elevation over the neighbouring country, and covered with Alpine plants to its summit. Nephin-beg, in its vicinity, is 2065 feet high. In the same district is the mountain of Berreencurragh, 2290 feet high; and more westward, Maam-Thomoish and Croughletta, each very lofty, though less elevated than the preceding. The rivers which flow from these mountains are small, unless when their body of waters is increased by a violent fall of rain. The principal are the Aull, which is navigable for large boats for 5 miles from Lough Mask; the Castlebar (or Clydagh) River, in like manner, navigable for 4 miles from Lough Conn; the Owenmore, an excellent salmon river, which flows through Erris, and falls into Blacksod Bay; the Deel, the Robe, the Errive, and the Carnamart. The splendid River Moy, which separates this county from Sligo, is navigable to within a mile of Ballina for vessels of 450 tons, and as a salmon river ranks second only to the Bann. The Black River, which is the boundary on the S., is remarkable for having an underground course of some miles near its embouchure into Lough Corrib. Amongst the numerous lakes, Lough Mask, situated in the S., and separated from Lough Corrib by a narrow isthmus, is the largest. It is 10 miles long by 4 broad, but its southern extremity is included in Galway county. Lough Carra, to the N.E. of Lough Mask, is a picturesque sheet of water, but much inferior in this respect to the beautiful Lough Raheens, called also Castlebar Lough from the town in its vicinity; and Lough Conn, still farther N., is a fine sheet of water 12 miles long, including Lough Cullin, but of very inconsiderable breadth. The minor lakes are numerous, and there are several turloughs, in which the water collects in winter, but is carried off by a natural drainage at the beginning of summer.

The western and northern coasts are indented with numerous bays and creeks. Killary Bay, or the Killary, which separates Mayo from Galway, is a narrow inlet of the sea, reaching 8 miles from the Atlantic, and only about half a mile in breadth, bounded on both sides throughout its entire length by mountains which, on the Mayo side, rise to nearly 3000 feet in height, and resembling the scenery of a Norwegian fiord. Proceeding northwards, the next inlet in order, and the most worthy of note for extent and grandeur of scenery, is Clew Bay, protected at its entrance by Clare Island, and having in its interior the two harbours of Newport and Westport, besides many creeks and roadsteads caused by the almost innumerable islets with which its eastern coast is studded. Blacksod Bay and Broadhaven form the peninsula of the Mullet, and are prevented from blending their waters only by the very narrow isthmus of Bellmullet. On the northern coast are Dunfinney and Killala Bays. The lesser indentations of the coast, affording shelter for small craft, and therefore of much importance to the fisheries, are too numerous to admit of specific detail.

The principal island is that of Achill. It is the largest on the Irish coast, containing 35,283 acres, and about 3500 inhabitants, and is formed partly of lofty hills and partly of flat bogs. The western side presents a rugged and precipitous line of rock to resist the violence of the Atlantic, interrupted only by a few small coves, scarcely capable of sheltering the smallest boats; the eastern coast affords shelter almost everywhere. The highest mountain on the island, Slievemore, situated to the W. of the Protestant missionary settlement, is 2204 feet above the sea; and other summits attain elevations of 2192, 1800, and 1120 feet. Clare Island is of a triangular form, 3959 acres in extent, and has about 1400 inhabitants. Innisbofin, the most important island on the coast as respects the fisheries, is about 4 miles from Connemara in Galway; it had a garrison in the time of the republic. The finest cod-bank on the Irish coast lies near it. Innisturk lies midway between the two last-named islands. The want of a landing-place renders it nearly useless, notwithstanding its advantageous position for fishing. It comprehends 1450 acres of poor soil and rock. The lesser islands are scarcely of sufficient consequence to deserve enumeration.

The returns of the population of the county, taken at different periods, present the following results:—

Year.	Authority.	Population.
1760	De Burgo	77,508
1792	Beaufort	140,000
1812	Parliamentary return	261,821
1821	Ditto	293,112
1831	Ditto	366,328
1841	Ditto	388,887
1851	Ditto	274,612

The latest of these returns shows a decrease of population in 10 years of 114,275, or 29 per cent. As far as may be conjectured from the relative numbers of Protestant and Catholic children attending public schools in 1824–26, the proportion between the sects is upwards of 7 to 1 in favour of the latter persuasion.

The returns of the numbers educated are as follows:—

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821	6,150	3185	—	9,335
1824–6	10,827	5172	694	16,993

Of the numbers in the latter return, 1900 only were Protestants. In 1851 the number of schools, and of pupils attending them, during the week ending 12th of April, was found to be:—

SCHOOLS.	No. of Schools.	Number of Pupils.		
		Males.	Females.	Total.
National	119	2920	2400	5320
Church Education	26	462	444	906
Endowed	2	55	32	87
Boarding	2	15	15	30
Private	98	1734	992	2726
Parochial	7	152	136	288
Free	11	229	548	777
Industrial	6	17	234	251
Mission	59	860	1121	1981
Military	1	13	5	18
Workhouse	18	2075	2162	4237
Gaol	1	41	7	48
Total	350	8573	8096	16,669

The county was represented in the Irish Parliament by four members, two for the county at large, and two for the borough of Castlebar; but the two latter were struck off at the Union, and compensation, amounting to L.15,000, awarded to the Earl of Lucan, as proprietor of the borough, for the loss of the patronage. No alteration having been since made under the Reform Act, the number of representatives is now limited to two.

The number of resident landed proprietors is small in comparison with the extent of the county. The condition of the peasantry varies considerably according to their situation. On the sea-coast, where the occupation of fishing can be combined with that of agriculture, the people are tolerably comfortable. This is particularly the case in the district around Killala, Westport, Newport, and other places where an export trade is carried on; and early and improvident marriages are by no means so common in those parts. Similar appearances of comfort and prudence are observable in the inland eastern districts where agriculture is attended to. In the mountainous and boggy tracts the state of the peasantry is very deplorable. The houses are of the poorest description, and extremely confined in dimensions. But in the agricultural districts the case is different. In these the houses are of stone and mortar, with a chimney and separate apartments. The men dress in home-made frieze of a dark colour, and the women mostly in cheap cottons. The fuel is universally turf; the food potatoes, with milk occasionally, and when near the shore, fish. The Irish language is understood by 65 per cent. of the population, and about 50,000 persons are unable to speak the English language. In the inland and more retired parts the peasantry prefer collecting themselves in closely-built, irregular villages, to living in detached cottages. The custom of holding large tracts of land in joint tenancy, which is the favourite tenure in the pasturable regions, may be considered as the chief cause of this practice.

The soil in the plain country is chiefly a gravelly loam on a limestone bottom. Even in the tracts where bogs prevail, ridges of limestone gravel, called *eskers*, of a mile and more in length, several perches broad, and from 40 to 50 feet high, are to be met with. The rocky pastures produce a nutritive herbage for sheep and young cattle; and in places from which these are excluded, timber trees throw up their shoots spontaneously. Wheat is grown in large quantities in the southern and eastern baronies; oats, barley, and flax in the hilly country.

The extent of land under crops, and the number of acres under each species of crop in 1855 and 1856, was:—

	1855. Acres.	1856. Acres.
Wheat	4,638	6,086
Oats	83,543	84,249
Barley, bere, rye, pease, and beans	5,396	4,252
Potatoes	59,037	67,230
Turnips	9,556	10,604
Other green crops	2,193	2,227
Flax	745	923
Meadow and clover	18,229	16,964
Total	183,337	192,535

Where limestone can be had it is the favourite manure, either alone or in a compost with other substances. Where it cannot be procured, recourse is had to burning. Shelly sea-sand, and sea-weed thrown up by the high winds, are much used on the coast. The implements of agriculture are still of a clumsy and coarse make. The spade, called a *loy*, having a rest for the right foot only, is substituted for the plough in the mountainous parts. In Erris a spade with a blade forking out into two points is used where the soil is rocky. The fences are mostly dry-stone walls, formed by collecting the loose stones from the surface, where they are so abundant that the fences made of them present the appearance of ramparts rather than inclosures against trespassing.

The quantity of live stock in the county of Mayo in 1855 and 1856 was:—

	1855. No.	1856. No.
Horses	17,531	19,300
Cattle	153,583	157,856
Sheep	265,448	270,074
Pigs	38,348	33,372

Towards the close of the last century, planting, both for ornament in demesnes, and on a more extensive scale for profit, has been much attended to. The base of Croaghpatrick is finely fringed with wood, as is that of Nephin. The neighbourhood of Westport is much improved by extensive plantations. The baronies of Tyrawley, Burrishoole, Gallen, and Costello, however, are nearly destitute of timber.

The manufactures are almost wholly confined to articles in demand for home consumption, such as linens, furs, flannels, woollen stockings, and straw hats. The chief marts for the sale of the superabundant produce are Castlebar and Westport. Besides these legal sources of profit from manufactures, illicit distillation is still carried on to some extent. The exports are grain, fish, and kelp; large quantities of the latter are manufactured on the shores. Fishing banks are numerous. The principal one, between Innisbofin and Achill, affords an inexhaustible supply of white fish. Near Achill is a sandbank stocked with turbot and other flat fish, which are also taken in abundance off Killala Bay. Near Inniskea Island is a great ling bank. The sun-fish, or basking shark, is taken from 5 to 8 leagues from the coast. The fishery commences in the last week in April; but as the success of the season depends on the state of the weather, which is very liable to sudden and violent squalls at that season, and as the fish frequently escapes, bearing away with it the harpoon and tackle, the average profits, during a continuance of seasons, seldom compensate the adventurer for his outlay. The herring fishery occupies many hands. The whole fishing trade is carried on in open boats, as this description of craft is less expensive, and better adapted for the coasting trade in kelp and turf, in which it is employed during the intervals of the fishing seasons. The deep-sea fishing begins in May; that of the herring in August. The winter fishing continues from November to Christmas. Pollock, whiting, sand-eels, and shell-fish are caught along the shores, and there are salmon fisheries at Newport, Ballina, and other places.

The remains of ancient buildings are numerous, and many of them highly worthy of note. There are round or pillar towers at Killala, Turlough, Meeleek, and Bal; but the first, which stands on an eminence in the town, is the loftiest and best preserved. The Abbey of Mayo, which gives name to the county, was once the site of a bishop's see. Moyne Abbey, beautifully situated on the banks of the bay, near Killala, still exhibits some arches of magnificent size and excellent workmanship, with a tower rising not less than 100 feet from the top of the centre of the church. The ruins of Rosserick Abbey, in a sheltered dell near the estuary of the Moy, about 4 miles from Killala, are amongst the finest specimens of monastic buildings in the county. The workmanship of an arch in the centre of the church is peculiarly admirable. Although Ballyhaunis Abbey is much dilapidated, the remains of its ruins show it to have been, as it were, a miniature resemblance of that of Moyne. At Ballinrobe was the Abbey de Roba, of which no traces are now visible. Ballintobber Abbey, about 5 miles from Ballyglass, was founded by Cathal O'Conor, King of Connaught. The Abbey of Burrishoole, 2 miles distant from Newport, owes its origin to the Bourke family; its site is the place for holding a patron in honour of St Dominic. The remains of the church of Strade Abbey, on the Moy, still exist; they are singularly beautiful, and near the altar are several curious sculptures. Cross, or Holycross Monastery, was in the peninsula of the Mullet. The Abbey of Bophin was built in the island of Innisbofin. Many relics of other monastic buildings of inferior note are to be found in various parts. The remains of ancient castles and places of strength are also numerous. At Downpatrick, or Dunbriste, are the ruins of a strong castle on a cliff, 300 feet high, projecting into the sea. A rock of equal elevation rises at about the same distance from the shore, on which are also the traces of castellated buildings. The correspondence of the prominences and indentations of the rocks on each side of the cleft that separates these structures prove that they were once united. Rockfleet Castle, near Newport, is said to have been built by the celebrated Grace O'Mallay, to whom the erection of several other fortresses along the coast are attributed. This singular woman was so much attached to the sea, the scene of most of her exploits, that when on shore, she is said to have had her bark moored to her bed-post through a window of the castle where she slept. Ballylahan Castle, near Foxford, was built by one of the MacJordan family, who erected others of similar construction for each of his ten sons. Deel Castle, near Ballina, stands as yet; it was formerly the residence of the Earls of Arran, and is still inhabited. In Lough Conn are the ruins of a fort in which O'Conor, king of Ireland, is said to have confined his son. The smaller castles, or fortified houses, vestiges of which are visible in many parts, are almost invariably square buildings, with a narrow entrance and a few contracted windows, erected solely for security, without any regard to architectural beauty.

The towns in this extensive county are few and small, none of them having a population amounting to 5000. The principal are,—Castlebar, Westport, Ballina, and Ballinrobe, which will be found described under their respective heads. (H. S—R.)

MAYOMBA, or Mayumba, a seaport of Africa, in South Guinea, is situated at the mouth of the Mayomba River, 120 miles N.W. of Loango. It is the capital of a territory of the same name, which is governed by a chief dependent on the King of Loango. The harbour is convenient. The inhabitants, who are gentle and intelligent, find employment in working copper and procuring ivory and gum.

MAYOTTA, an island in the Mozambique Channel, the farthest S. of the Comoro group, is situated about 160 miles from Madagascar, in S. Lat. 12. 54., and E. Long. 45. 15. It is about 30 miles in length by 20 in breadth, and is for the most part of volcanic structure. It is mountainous, rising in some parts to the height of nearly 2000 feet; and many valleys and ravines occur, while the whole is covered by forests and luxuriant vegetation. The coast is indented with numerous bays, &c., and is surrounded by reefs, which render the landing difficult. The villages are two in number,—Choa, or Mayotta, the residence of the chief; and Zaondzi, on an island of the same name, which is included within the encircling reef. Mayotta has suffered much from the Madagascar pirates. It has been in the possession of the French since 1841. Pop. (1854) 6888.

MAYOW, or Mayo, John, a medical man of some eminence, but more remarkable for his curious speculations on some chemical subjects, was born in Cornwall in 1645. His most interesting work is a short Latin treatise, *De Sale Nitro, et Spiritu Nitro-äereo*, which appeared at Oxford in 1674. In this he adopted the theory of combustion of Dr Hooke, which had appeared about ten years before; and he added some ingenious original experiments, in which he appears to have anticipated some far more recent investigations on the weight gained by metals on calcination; and he maintained that atmospheric air underwent a change in composition during the combustion of fuel. The apparatus he employed in these experiments was ingenious, and not very different from that of modern chemistry. But the attention of chemists was drawn away from the simple explanations of Hooke and Mayow by the fanciful speculations of Stahl regarding *phlogiston*. In the 14th chapter of his little treatise we find that the ideas of Mayow on chemical *affinity* were much more accurate than those of any of his contemporaries; and we must regard him as one of the pioneers of modern chemistry, though some of his views are undoubtedly erroneous, as might be expected from the period in which he lived. He died at Bristol in 1679, at the early age of thirty-four. (T. S. T.)

MAYPU, a river of Chili, in the department of Santiago, rises in the Andes, between the volcano of the same name and the Peak of Tupungato, flows westward, and, after a course of 160 miles, falls into the Pacific. For about one-third of its course, the river flows in narrow ravines among the high mountain ridges of the Andes; but in the lower part of its course it traverses the S. portion of the plain of Santiago, which it waters by means of a canal. Its waters are much impregnated with salt, and dash along with an impetuosity which no ordinary bridge could withstand. It is therefore crossed only by swinging bridges of ropes, on the model of those of the ancient Peruvians. The Rio de Colina, from the plain of Santiago, falls into this river. In the plains traversed by the Maypu, a great and decisive victory was gained in 1818, by the republicans under San Martin, over the royalists, which put an end to the Spanish dominion in Chili.

MAYSVILLE, a town in the state of Kentucky, Mason county, North America, is situated on the S. bank of the Ohio, 60 miles above Cincinnati, and 73 miles N.E. of Frankfort. The town, which formerly went by the name of Limestone from a creek of that name, consists of a number of regular streets, crossing each other at right angles, and containing many well-built houses and shops. The principal buildings are,—a city-hall, a jail, an hospital, 7 or 8 churches, 12 schools and seminaries, and 2 banks. Manufactures of iron, cotton, ropes, &c., are carried on here. Maysville is a place of considerable trade, especially in the agricultural produce of the north-eastern districts of the state, and it has an excellent harbour on the Ohio. Pop. (1853) 6500.

MAZAMET, a town of France, department of Tarn, situated on the small River Larn, a tributary of the Agout, at the foot of the Black Mountains, 10 miles S.E. of Castres. It is within the last forty years that this town has acquired its present importance; for previously it was only an obscure village in a barren and thinly peopled country. The town has a Protestant consistorial church; and manufactures of coarse woollen stuffs, moleskins, cloth, paper, &c. Its trade is also considerable, comprising, besides its articles of manufacture, corn, wool, cattle, &c. Pop. 9894.

MAZANDERAUN, or Mazenderan, a province of Persia, bounded on the N. by the Caspian Sea, E. by Khorassan, S. by Irak-Ajemi, and W. by Ghilan, and lying between 36. and 37. N. Lat., and 50. and 54. E. Long. Length about 200 miles from E. to W.; average breadth 50 miles; area 10,000 square miles. The province is bounded on the S. by the high mountains of Elburz, which are covered with wood; but the most part of it consists of a low plain on the shores of the Caspian. Near the sea the country is very marshy; but at a short distance it takes a gradual ascent. None of the rivers are of great size, and all flow northward into the Caspian. The climate is not very healthy; but it is not so insalubrious as that of the adjoining province of Ghilan. The soil is good, and produces rice, cotton, mulberry, and sugar cane; as well as oranges, pomegranates, and other fruits. Cultivation is carried on to a considerable extent; the chief article raised being rice. Its trade, which is principally with Russia, consists in the exportation of rice, silk, and cotton; and the importation of woollen stuffs, corn, tobacco, cutlery, &c. The inhabitants resemble in appearance and costume the other Persians; but they have the reputation of being more warlike and courageous. They are ignorant, proud, and very scrupulous and bigoted in their religious observances. There is also a tribe called Lak or Lek, supposed by some to be Kurds, who have one of their principal seats here. In the time of Timour the courage and determination of the people of this province, who defended themselves in their strongholds and mountain fastnesses, were so great as to give that conqueror considerable trouble in subduing them. Mazanderaun is also celebrated as the scene of some of the most famous exploits of Rustom, the Persian hero. The province is traversed by an artificial causeway, extending from W. to E. nearly parallel to the Caspian; which, though built more than 200 years ago by Abbas the Great, Shah of Persia, is in very good preservation at the present day. The principal towns are,—Sari, the capital, Amol, Balfrush, and Farahabad. Pop. 150,000.

MAZARIN, JULES (properly MAZZARINO, *Giulio*), son of Pietro Mazzarino, a noble Sicilian, was born at Piscina, in the Abbruzzi, on the 14th of July 1602. Having received his elementary education at Rome, he passed into Spain with the Abbé, afterwards Cardinal, Girolamo Colonna, at the age of seventeen, where he attended courses of law in the universities of Alcala and Salamanca. But he soon abandoned jurisprudence in order to embrace the military profession, and in 1625 was sent, with the rank of captain, into the Valteline, where the pontiff then had an army. From this time he began to display his talents for diplomacy. The generals of his Holiness, Conti and de Bagni, sent him successively to the Duca de Feria, general of the Spaniards, and to the Marquis de Cœuvres, afterwards Marshal d'Estrées, who commanded the French troops; and in both missions he acquitted himself in such a manner as to merit the commendations of these chiefs. He then returned to Rome, where he resumed the study of jurisprudence, and took his doctor's degree. But the disputed succession to the duchies of Mantua and Montferrat having kindled up a new war, he quitted law for diplomacy, in which line nature had peculiarly qualified him to excel. The competitors were the Duc de Nevers, whose cause was espoused by the court of France, at which he resided, and the Duca de Guastalla, who was supported by the emperor, the King of Spain and the Duke of Savoy. The pope, desirous to prevent a war, of which Italy was about to become the theatre, sent Cardinal Sacchetti to Turin to act in favour of the Duc de Nevers; and Mazarin accompanied him in this mission. Sacchetti returned to Rome unsuccessful, leaving to Mazarin the title of internuncio, with power to continue the negotiations, and to effect a peace. Mazarin first saw Louis XIII. at Lyons in 1630, and had a long conference with Cardinal Richelieu. The cardinal entertained the highest opinio nof him, and feeling that France wanted an able and devoted man in Italy, he succeeded in gaining the young diplomatist, who from this time openly showed himself favourable to the interests of France. He returned to Italy without having obtained any success in his mission, and the war continued; but the Duke of Savoy having died, his son gave his entire confidence to Mazarin, who immediately resumed the work of peace with fresh ardour. The Spaniards were besieging Casale, and the French wished to relieve the place; but by negotiating with the chiefs of both armies he induced them to consent to an armistice for six weeks. When this truce had expired he demanded a prolongation, which the French refused, and at the same time prepared to attack the lines. Mazarin then proposed a treaty, in which they stipulated the hardest conditions. To engage them to relax in their demands, he represented the formidable state of the Spanish army, and the hazard of an attempt to force their entrenchments; but failing to persuade them, he passed over to the Spaniards, reported to them the conditions required by the French, and, still employing the same logic, urged the superiority of the French, and their ardent desire for the combat. This time he succeeded. The Spanish general assented to everything. Mazarin immediately quitted the Spanish trenches, and riding at full gallop towards the French, regardless of the balls which whistled around him, waved his hat, exclaiming "Peace, peace." The soldiers repulsed him, crying out "No peace;" but he nevertheless addressed himself to the Mareschal de Schomberg, who accepted the treaty, and caused his troops to lay down their arms. This peace was confirmed the following year by the treaty of Cherasco, which was negotiated by Mazarin. About the same time he secured to France the town of Pignerol, and deceived both the Spaniards and imperialists, who had only evacuated Casal and Mantua on condition that the French garrison should quit Pignerol. Such conduct excited against him all the hatred of the Spaniards; but it earned for him the acknowledgements of Louis XIII. and of Richelieu, who commended him favourably to the pope. Through the influence of Richelieu he was sent in 1634 to the court of France, in the capacity of nuncio extraordinary. The object of this mission was to intercede in favour of the Duke of Lorraine, who had been deprived of his estates by Louis XIII.

In 1635 the Spaniards, by their intrigues with the sovereign pontiff, procured his recal to Avignon, and even attempted to get his vice-legation revoked; but he anticipated them, and demanding his immediate recal, he in 1636 returned to Rome, where he openly supported the interests of France. He was sent to Savoy by Louis XIII. during the troubles of 1640, with the title of ambassador extraordinary. The successes of the Compte d'Harcourt in Piedmont enabled him, in December 1641, to conclude a treaty between the Duchess of Savoy and her brothers-in-law, who, supported by Spain, had disputed with her the guardianship of her son. It was then that Mazarin obtained the cardinal's hat long since demanded for him by his friend Richelieu. He was included in the nomination of the 16th December 1641, and on the 25th of February 1642 he received the cap from the hands of Louis XIII. The intrigues which had pursued Richelieu during his whole life assumed fresh force towards its close, and on his death-bed he recommended Mazarin warmly to the king, who entrusted him with the direction of all affairs of state. Richelieu had governed by terror; but Mazarin preferred to make himself friends. He obtained the release of Marshal de Bassompierre, Marshal de Vitry, and many other victims of the last minister, recalled several exiled members of parliament, and contributed to the reconciliation of the Duc d'Orleans with the king.

On the death of Louis XIII. on the 14th of May 1643, the administration of affairs was placed entirely in the hands of Mazarin. The commencement of his sway was attended with the happiest success; and the advantages gained by the king's armies secured to the cardinal the applause of the nation. But these favourable dispositions were soon succeeded by the murmurs, not loud but deep, of an oppressed people, and also by a combination of the high nobility who were jealous of his advancement and power. The civil wars of 1649, 1650, 1651, and 1652, followed; his dismissal was at length insisted on, and Mazarin immediately withdrew from the kingdom. Decree upon decree was fulminated against him; his fine library was sold; and a price was even put upon his head; yet, in spite of all the rage of his enemies, he was enabled to return to court with greater power than ever; and many who had formerly been his bitterest enemies now became his warmest friends. He put an end to the war between France and Spain, and, in order to consolidate the peace he had re-established, negotiated a marriage between the king and the infanta, which was celebrated at Sant-Jean-de-Luz on the 9th of June 1660. He died at Vincennes on the 9th of March 1661, in the fifty-ninth year of his age. Mazarin was but little regretted. A courtier writing at the time, says, "*Le roi est, ou parait, le seul touché de la mort du cardinal.*" He had accumulated immense wealth by very doubtful or equivocal means. His fortune is said to have amounted to near eight millions sterling, all acquired in a period of external war or of internal commotion. On the approach of death he felt some scruples of conscience on the subject, which were, however, soon got over.

The only productions of Mazarin which have been published are his letters. Of these, thirty-six, written by him whilst negotiating the peace of the Pyrenees, made their appearance in the year 1690; and seventy-seven more on the same subject were published in 1693. The whole were collected and reprinted at Amsterdam, in two volumes, under the title of *Negociations Secrètes des Pyrenées*. The

Abbé Allainval afterwards arranged these letters in chronological order, and, together with fifty unpublished letters, brought them out under the title of *Lettres du Cardinal Mazarin, où l'on voit le Secret de la Negociation de la Paix des Pyrenées*, Paris, 1745, in two vols. 12mo.

The character of Mazarin, who was a thorough Italian in diplomacy, has been compared, or rather contrasted with that of Richelieu, and variously shaded according to the opinions and predilections of those by whom it is delineated. "Cardinal Mazarin," says Hénault, "was as gentle as Cardinal Richelieu was violent; one of his greatest talents consisted in knowing men thoroughly. The character of his policy was rather finesse and prudence than force. He thought that force should never be employed but in default of other means; and his mind supplied the courage required by circumstances; bold at Casale, tranquil and active in his retreat at Cologne; enterprising when it was necessary to cause the princes to be arrested, but insensible to the pleasantries of the Fronde; despising the bravadoes of the coadjutor, De Retz, and listening to the murmurs of the people as one listens on the shore to the noise of the waves of the sea. There was in Cardinal Richelieu something greater, vaster, and less composed; in Cardinal Mazarin, more address, more management, and fewer extravagances. People hated the one and derided the other; but both were masters of the state."

MAZEPPA, John, the hero of one of Lord Byron's poems, was born about the middle of the seventeenth century, of a poor but noble family, in the palatinate of Podolia. At an early age he became a page at the court of John Casimir, King of Poland. After some time he returned to his native province; but engaging in an intrigue with a Polish matron of high rank, he was detected by the injured husband, and was sentenced to be bound naked on the back of an untamed horse. The animal on being let loose galloped off towards its native wilds of the Ukraine, and arrived there jaded and worn out. Mazeppa half-dead and insensible, was released from his fearful position, and restored to animation by some poor peasants. In a short time, his agility, courage, and sagacity, rendered him popular among the Cossacks. He was appointed secretary and adjutant to Samoilowich, their hetman or chief, and succeeded that functionary in 1687. The title of prince was afterwards conferred upon him by his friend and patron, Peter the Great. Bent, however, upon casting off the Russian yoke, Mazeppa became, in his seventieth year, an ally of the Swedish monarch, Charles XII. After the disastrous battle of Pultowa, fought, it is said, by his advice, he retired to Bender, and there he died in 1709.

MAZZARA, a seaport of Sicily, province of Trapani, situated on the W. coast, near the mouth of the Salemi, 11 miles S.E. of Marsala, and 26 S. of Trapani. The town is ill built; and though from the sea the domes of the churches present a fine appearance, yet when more closely approached it is found to be chiefly characterized by narrow and dirty streets. There is a public square, of a curious antique appearance, in which stand the cathedral, with a fine dome, and an equestrian statue of Count Roger the Norman (who landed here for the conquest of Sicily) over the gate; also the bishop's palace, and the senate-house. Besides these, the town contains numerous churches and convents, a college, hospital, theatre, and granary. It is surrounded by an old Saracenic wall, with small towers, and there is also an old castle in a ruinous condition. The harbour, though large, is not good, being shallow, and only accessible to small vessels. The road also is unsheltered; but notwithstanding these disadvantages the trade is considerable; and the town exports corn, wine, fruits, fish, oil, soap, &c. Pop. 8400.

MAZZOCCHI, Alessio Simmaco, an Italian writer, was born near Capua in 1684, and died at Naples in 1771. Having by dint of personal application acquired a knowledge of the Greek, Latin, and Hebrew languages, he was nominated a canon of the Neapolitan diocese, and ultimately appointed professor of biblical exegesis in the university of Naples. His name was first known among learned men through his commentary *Dell' Anfiteatro Campano*, in which he elucidates the early history of Capua, and proves, among other things, that it was the first of the eighteen Roman colonies established in Italy. In connection with his professorship he wrote a work named *Spicilegium Biblicum*, the most comprehensive of the older encyclopædias of sacred and profane learning extant; in which Homer, Hesiod, Herodotus, Plato, and most of the ancient authors, are made to contribute to the elucidation of Scripture. The other work on which Mazzocchi's fame chiefly rests is the *Commentario sopra le due tavole Eraclensi;* so called because these tablets were found in the neighbourhood of Heraclea, in *Magna Grecia*. The other works of this author are,—*De dedicatione sub ascia*, Naples, 1738; *Dissertazione sopra l'origine de' Tirreni*, Rome, 1740; *De antiquis Corcyræ nominibus schediasma*, Naples, 1742; *In vetus marmoreum S. Neapolitanæ ecclesiæ Kalendarium commentarius*, ibid., 1744; *Diatribe de librorum bipatentium et convolutorum antiquitate*, ibid.; *Opuscula oratoria, epistolæ, carmina, et diatribe de antiquitate*, ibid., 1775; an improved edition of the *Etymologia linguæ Latinæ*, by Vossius, Naples, 1762; and other less important works. (See Fabroni, *Vitæ Italorum.*) (E. F.)

MAZZUCHELLI, Conte Giovan Maria, a learned jurisconsult and biographer, born at Brescia in 1717. The first result of his studies was the *Notizie Storiche e critiche intorno alla vita e agli scritti d'Archimede*, Brescia, 1737, in which he explains the inventions of the celebrated Syracusan, and offers suggestions on the mirrors which are said to have set fire to the ships of the Consul Marcellus, and concludes by doubting the authenticity of the fact; thus anticipating the French academician, who afterwards established mathematically the argument *De falso speculo Archimedeo*. The author, encouraged by the success of this work, formed the vast design of including in one work all the literary and scientific achievements of Italy from the earliest times. Accordingly, in 1753, he published at Brescia the first two folio volumes of his work in alphabetical order, which completed the letter *A*. These were followed by four volumes on the letter *B* in 1758–63, the last which he survived to finish. He died a few years after, leaving behind him a vast collection of ancient codes, manuscripts, casts, and medals, which were afterwards engraved and given to the world, with a description by the Abbé Pietro A. Gaetani at Milan. The *Dissertazioni Storiche, scientifiche ed erudite*, 2 vols. 4to, Brescia, 1765, were the result of the *litterarie conversazioni*, or literary society, which met at his house. Count Mazzuchelli also wrote the *Vite di Scipione Capece e di Giusto de' Conti*, Brescia, 1769; *Notizie intorno ad Isotta da Imola*, ibid.; essays published in the literary periodicals of his day; many letters; and an edition of the *Vite d'uomini illustri Fiorentini di Filippo Villani*, with additions, corrections, &c. (See *Rodella*, Vita del C. G. B. Mazzuchelli, Brescia, 1766; and *Bragnoli*, Elogi de Bresciani, ibid., 1785.) (E. F.)

MEAD, Dr Richard, an eminent English physician, was born at Stepney, near London, in 1675. At sixteen years of age he was sent to Utrecht, where he studied three years under the celebrated Grævius; and then choosing the profession of physic he went to Leyden, and attended the lectures of Pitcairn and Hermann. Having visited Padua in 1695 he took his degree of doctor of philosophy and physic; and returning home he settled at Stepney, and practised physic with great success.

In 1703 Dr Mead was elected a member of the Royal Society, of which Sir Isaac Newton was then president.

The same year he was elected physician of St Thomas's Hospital, and was also employed by the surgeons to read anatomical lectures in their hall. In 1707 his Paduan diploma for doctor of physic was confirmed by the university of Oxford; and on the death of Dr Radcliffe, Mead enjoyed the most extensive practice of any physician of his day. In 1727 he was made physician to George II., whom he had served in that capacity whilst he was Prince of Wales.

During almost half a century he was at the head of his profession, and he was admired no less as a man than as a physician. His reputation, not only as a physician, but as a scholar, was so universally established, that he corresponded with the principal literati in Europe. It was principally to him that the several counties of England, and our colonies abroad, applied for the choice of their physicians, and he was likewise consulted by foreign physicians from Russia, Prussia, Denmark, and other countries. Mead's principal works are,—*A Mechanical Account of Poisons*, 1702; *De imperio Solis et Lunæ in Corpora Humana, et Morbis inde oriundis*, 1704; *A short Discourse concerning Pestilential Contagion*, 1720; *On the Scurvy*, 1749; *On Small-pox and Measles*, 1748; *Medicina Sacra, seu de Morbis insignioribus qui in Bibliis Memorantur*, 1748; *Monita et Præcepta Medica*, 1751. His works, which were written in Latin, were afterwards translated into English by Dr Thomas Slack, and received the author's revision. They passed through many editions both in this country and on the Continent. (See *Authentic Memoirs of the Life of Richard Mead*, M.D., by Matthew Maty, M.D., 8vo, London, 1755.) This great physician, naturalist, and antiquary, died on the 16th of February 1754.

MEADAY, a town of Eastern India, situated on the left bank of the River Irrawaddy, in the British province of Pegue, 35 miles N. of Prome. The frontier line, running E. and W., and separating the dominions of the King of Burmah from the recently acquired province of Pegue, passes close to this town. Lat. 19. 17., Long. 95.

MEASURES. See WEIGHTS and MEASURES.

MEATH, a maritime county in the province of Leinster in Ireland, is bounded on the N. by the counties of Cavan, Monaghan, and Louth; on the E. by the Irish Sea and Dublin county; on the S. by the counties of Kildare, Dublin, and King's County; and on the W. by Westmeath. Its superficial area is 906 square miles, or 579,899 acres, of which 547,424 are arable, 16,000 uncultivated, 12,767 in plantations, 464 in towns, and 3244 under water. Meath contains a much smaller proportion of uncultivated land than any other county in Ireland; and of the 16,000 acres of bog and coarse pasture land comprised within its boundaries, it is probable that 6000 acres are capable of improvement for cultivation, 8000 may be improved by draining, and not more than 2000 acres are unimprovable.

In the time of Ptolemy it formed part of the territory of the Eblani, whose settlement extended from the Boyne to the Liffey. According to the accounts of native writers, the district known by the name of Meath was of much greater extent than at present. It comprehended the modern counties of Meath, Westmeath, Longford, with parts of Cavan, Kildare, and the King's County, and constituted the least, but the best and most fertile, of the five subordinate kingdoms into which the island was divided. At the time of the landing of the English the O'Melaghlins ruled in Meath, and from them it was wrested by Henry II., who bestowed it on Hugh de Lacy, to be holden by the service of fifty knights. This nobleman subdivided it into twelve parts called baronies, because the persons to whom he granted those parts were afterwards created barons. In this state it continued till the reign of Henry VIII., when it was divided by act of parliament into the two counties of Eastmeath and Westmeath. The modern division of the county is into eighteen baronies. Deece, Lower and Upper; Duleek, Lower and Upper; Dunboyne; Fore; Kells, Lower and Upper; Lune; Morgallion; Moyfenrath, Lower and Upper; Navan, Lower and Upper; Ratoath; Skreen; and Slane, Lower and Upper. These baronial divisions are again subdivided into 146 parishes.

According to the ecclesiastical division of Ireland this county constitutes the greater portion of the diocese of the same name; but a few of its parishes are in the dioceses of Armagh and Kilmore. There were formerly many episcopal sees in Meath, all of which, except Kells and Duleek, which, however, subsequently shared the same fate as the others, were consolidated previously to the year 1152, when Cardinal Paparo settled the diocesan divisions of Ireland, by authority from Pope Eugenius III. The seat of the see was then fixed at Clonard. The bishopric of Clonmacnois was united to it by act of parliament in 1568. The bishop of Meath has no cathedral church; his residence has for a long period been at Ardbraccan, about 3 miles from Navan, which in the wars of 1641 was a castle of considerable strength, but is now a tasteful modern mansion, and one of the finest of the episcopal palaces in Ireland. The constitution of the diocese possesses many singularities. There is neither dean nor chapter. The only dignitaries are the dean of Clonmacnois, and the archdeacon of Meath. The want of a chapter is supplied by a synod, of which every beneficed clergyman within the diocese is a member. This synod has a common seal, which is lodged in the hands of members annually selected for its custody. The Bishop of Meath takes precedence of all the other suffragan bishops in Ireland, and is a member of the privy council in right of his see.

The surface of this county, though generally level, is yet not without its characteristic beauties. The banks of the Boyne, especially, present a succession of prospects in which the undulating surface is richly ornamented with the natural beauties of wood and water, studded by numerous buildings, both ancient and modern. Few of the elevations are of sufficient height to be termed hills, except Slieve Naccalliagh (904 feet), and Lloyd (422 feet), in Kells barony; and even these, where cultivated, are productive to their summits. The latter is surmounted by a pillar 100 feet in height, erected by the first Earl of Bective, from which a fine view of the rich level plain of Meath may be obtained.

The River Boyne enters the county at its south-western extremity, and intersects it diagonally in a north-eastern direction, pursuing a quiet gentle course, through a rich and fertile country, till it discharges itself into the sea below Drogheda, where it forms the boundary between the counties of Meath and Louth. It receives the Blackwater at Navan. The Moynalty or Borora is a branch of the Blackwater. The Nannywater discharges itself into the Irish Sea. The Ryewater forms part of the boundary between Dublin and Meath. The Boyne is navigable for barges as far as Navan, whence a canal has been carried to Trim. The Royal Canal touches the southern border of the county between Kilcock and Cloncurry. The sea-coast is confined to the short space between the mouth of the Boyne and the stream of the Delvin, which is part of the boundary of Dublin county. It presents a shelving strand, without a port of any consequence. There is no sheet of water meriting the name of lake, except that of Lough Sheelin, which bounds the county on the N., being situated partly also in the counties of Cavan and Westmeath, and the very inconsiderable Lough of Lakefield, in Demifore.

The soil is extremely variable, being found of every quality, from a deep rich loam to the lightest sandy earth; but that most generally to be met with is a strong deep clay, resting on a substratum of limestone gravel. In some parts, and even on the tops of the hills, as good earth has been found at the depth of 4 feet as at the surface.

The county is wholly included within the great central plain of floetz limestone, which crosses Ireland in a broad band. The mineral productions are few, owing partly to the character of the soil, and partly to that of the surface, which, from its general flatness, prevents the interior from being explored to any depth, without being impeded by subterraneous water. A copper mine was for some time worked in Skreen barony, but the latter of the causes now mentioned put a stop to the operations. Limestone of large scantling, well suited for building purposes, and also susceptible of a high polish, is raised at Ardbraccan. It is white when fresh from the chisel, but assumes a greyish hue from atmospherical exposure. Argillaceous clay, which has been applied to the manufacture of coarse earthenware, is raised in some places. In Slane barony *coal-smut* has been found in abundance, at the edges of streams, where the soil has been washed away by the action of the water; but coal has not yet been discovered.

The population of a district enjoying so many of the natural advantages suited to the maintenance of human existence, was probably in early times more numerous than in most other parts of the kingdom; but in consequence of the conversion of the greater portion of its surface into pasture land, the operation of the clearance system has for some time past reduced the number of its inhabitants, in proportion to the extent of cultivated land, to much less than in any other Irish county.

The population of the county in modern times has been stated as follows:—

1760	De Burgo	81,516
1792	Beaufort	112,400
1812	Par. return	142,579
1821	Do.	159,183
1831	Do.	176,826
1841	Do.	183,828
1851	Do.	140,750

Meath returned no fewer than fourteen representatives to the Irish parliament,—two for the county at large, and two for each of the boroughs of Trim, Navan, Athboy, Duleek, Kells, and Ratoath. This number was reduced to two at the Union, all the representatives for boroughs having been struck off.

In 1851 the number of schools and of pupils attending them during the week ending 12th April was:—

Schools.	No. of Schools.	No. of Children.		
		Males.	Females.	Total.
National	82	2730	2690	5420
Church Education	6	96	62	158
Endowed	6	495	490	985
Boarding	2	111	...	111
Private	54	876	610	1486
Parochial	13	179	125	304
Free	12	143	234	377
Workhouse	7	945	896	1841
Gaol	1	87	...	87
Total	183	5662	5107	10,769

There are charter-schools at Trim and Ardbraccan, a school endowed at Navan by a bequest of Alderman Preston in 1686, and a large free school was established at Oldcastle by a bequest of Mr Gibson of London.

The population is chiefly engaged in agriculture. The soil being principally composed of a deep rich earth, the deepest ploughing is considered as the best tillage. A complete summer's fallow at stated intervals is considered necessary to keep the land thoroughly clean; every other attempt to eradicate the weeds, by means of clover, vetches, or any other umbrageous green crop, having proved ineffectual. Planting potatoes, even without manure, is considered as a good method of fallowing where cleansing is the only object. In the neighbourhood of villages it is a common practice for farmers to throw open the field which he intends to fallow to the cottagers, who furnish manure and plant their potatoes on it. If the ground be in good heart, he charges them at the rate of somewhat more than his own rent, which is termed "paying the standing rent;" but if poor, he makes no charge. With respect to the rotation of crops, or system of cropping, no restriction is imposed on the tenant. Every one is permitted to raise that kind of grain from which he expects to derive the greatest produce.

The crops usually cultivated are,—wheat, oats, barley, bere, rye, clover, flax, potatoes, cabbage, rape, turnips, and pease. The red wheat is preferred by most as agreeing best with the soil, and having a thinner rind, bearing the change of season better, and being less apt to lodge than the white. The latter is cultivated on the lighter and more gravelly soils. It comes in earlier, but is more liable to injury from the weather or mildew. Oats are produced in the greatest variety and of the finest samples. Barley is sown on the richest land, and requires the nicest tillage; and it is considered as one of the most profitable crops. Bere is a good deal sown, particularly after potatoes; it is also a profitable crop where it succeeds, but it is uncertain. The straw makes excellent fodder for young cattle. Rye, by itself or mixed with wheat, when it is called *meslin*, is chiefly ground into whole meal for domestic consumption. Flax is mostly sown in small patches for the use of the farmer's family, and seldom offered in quantities for sale; it grows strong and luxuriant, so as to be seldom fitted for the finer fabrics. When a field is laid down for grass, those parts of it on which flax had been grown produce the most luxuriant herbage, and show the earliest verdure in the following year. Rape is grown with the greatest success on bog which has been reclaimed by burning. Red clover is much used as a renovating crop; white clover is seldom sown except on land laid down for pasture.

The total extent of land under each description of crop in 1855 and 1856 was as follows:—

	1855.	1856.
Wheat	18,764	23,398
Oats	86,831	78,302
Barley, bere, rye, beans, and pease	4,876	3,633
Potatoes	19.235	21,898
Turnips	9,904	9,261
Other green crops	4,005	4,007
Flax	266	213
Meadow and clover	64,646	60,557
Total	208,527	201,269

The quantity of artificial grass sown is very small, as compared with the extensive tracts producing natural grasses; the depth and richness of the soil throughout almost the whole of the county, and its tendency to moisture without being absolutely wet, making it throw up a coat of nourishing herbage scarcely equalled in Ireland. In other counties there are districts which far exceed the richest lands here; such are the Golden Vale in Tipperary, and the corcass lands in Limerick. But no other district can exhibit 560,000 acres in close proximity of such excellent quality, and so appropriate to every purpose of tillage and pasture, as Meath. It is, generally speaking, more friendly to the latter kind of agriculture, and consequently was almost wholly applied to grazing, until the legislative measures adopted by the Irish parliament for the encouragement of tillage induced many to break up the large tracts which for ages had continued untouched by the ploughshare. The superior excellence of the beef reared here over that of any other district has made the county proverbial for its feeding. All the old pastures are composed of grasses of the best kinds. Graziers seldom think of procuring any particular species, from an opinion that the land, after three years, will revert to its natural herbage, even though grasses of other kinds had been sown upon it when laid down. Dry gravelly soils throw up a rich coat of white clover, though no red has been sown; and grounds of a clayey nature, when drained and manured with limestone gravel, often exhibit a similar tendency. Natural meadows are to be met everywhere; few farms, whatever be their size, are without a sufficiency for the holder's use. The artifical grasses chiefly cultivated are clover and trefoil. Much attention is paid by the graziers to the treatment of their feeding stock. The first week in May the pastures are generally opened for the summer stock, which are seldom reared here, the land being deemed too valuable to be given up to young cattle. Beasts of this description are brought from Connaught or Munster. When they arrive they are bled and turned into the pasture-field, where they remain till completely fattened, each field being stocked at once with its full complement. They are then sold partly in the Dublin market for the consumption of the metropolis, or for exportation to Liverpool. The sheep, like the cattle, are seldom bred in the country, but are bought at the October fair of Ballinasloe. Lands newly laid down are generally appropriated to the rearing of lambs for the Dublin market.

The quantity of live stock in the county of Meath in 1855 and 1856 was—

	1855.	1856.
Horses	23,310	23,646
Cattle	135,485	140,813
Sheep	170,582	189,029
Pigs	22,425	17,546

There are about 11,000 holdings exceeding one acre in extent, and most of the farmers occupying from 30 to 100 acres keep a few cows, the produce of which, both in milk and butter, that remains after supplying their own families, is sent to market. There are also a number of dairy farms in Dunboyne and Ratoath, on which the landlord supplies the land, houses, and stock; the tenant furnishes labour and utensils, and pays for the mowing and hay making. Cheese is very seldom made, and only for domestic use.

The quantity of natural wood throughout the country is small, but the plantations in demesnes and about gentlemen's seats, are numerous and thriving. The trees most usually met with are ash, elm, sycamore, lime, and larch. Scotch and spruce fir are less common. The oak is very scarce, the principal growth of it being at Loughcrew, in Demifore. There are many osieries, of from 2 to 10 acres each, the produce of which is sold to the basket-makers of Dublin.

The manufactures are chiefly confined to the making of sacking from tow, of course linens in the neighbourhood of Drogheda, where the cotton manufacture is also carried on to some extent, and of linens of a texture somewhat finer in the western baronies. Some coarse frieze is also manufactured for home consumption. There are paper manufactories, distilleries, breweries, and tanyards in several localities, but the number of persons in this county employed in manufacturing occupations is very small. The chief outlet for the produce of the county is Drogheda. There are good markets for grain and provisions at Trim and Navan, and extensive flour-mills on the Boyne and Blackwater.

There are several mansions in this county of great size and splendour, surrounded by highly improved demesnes, and numerous seats of resident gentlemen. The farm houses are generally of very inferior construction, formed of the earth or clay taken off the surface of the spot on which the house is to be built; hence the floor is commonly several inches below the level of the soil, and consequently damp and unwholesome. The habitations of the labourers and cottars are of a description still worse, being built of mud, and often with sunken floors. The owners of some estates, however, have provided comfortable residences for their labourers, to be held by them on moderate terms. In many parts the lower classes suffer from want of fuel; bog-land being extremely scarce, and the expense of carriage precluding the purchase of coal, which must be drawn from Dublin or Drogheda.

The peasantry of Meath are generally a fine, well-looking and healthy race, but more phlegmatic and serious than the inhabitants of the mountain districts of Ireland; and owing to the early occupation of this portion of the country, and its situation within the English pale, the admixture of races is very great.

Amongst the most ancient remains of antiquity may be mentioned the round or pillar towers at Kells and Donaghmore. The former is a very perfect specimen of these peculiar structures, 99 feet high, and has four small apertures near the top facing the four cardinal points of the compass. The latter, also very perfect, is remarkable for having a representation of the Saviour on the cross, carved on the key-stone over the entrance, which some antiquaries consider a decided proof that these structures were not built by the pagans; while others, anxious to support the theory of the pagan origin and the antiquity of the Irish round towers, assert that this doorway is not the original one. At Kells is a fine ancient sculptured cross of beautiful workmanship, and another of plainer construction at St Kieran, about 3 miles from Kells. At New Grange, near Slane, is a pagan relic of great interest, consisting of an artificial cavern or underground gallery, in the form of a cross, 71 feet in its greatest length, 20 feet between the extremities of the arms of the cross, and 11 feet in its greatest height, surrounded by a tumulus or hillock raised by art, which is surrounded by a circle of huge unhewn stones set upright. "It is," says Dr Wilde in his interesting work on the beauties of the Boyne and the Blackwater, "probably one of the oldest Celtic monuments in the world, which has elicited the wonder and called forth the admiration of all who have visited it, and has engaged the attention of nearly every distinguished antiquary, not only of the British Isles, but of Europe generally." It is supposed to have been either a place of Druidical worship or a burying-place; and two skeletons, uncovered with earth, were found in it when first opened. The Hill of Tara, a few miles S. of Navan, is famous as being the place where the kings of Ireland were crowned, and where the states of the island held their triennial assemblies, called the Fez of Tara. The traces of some of the localities supposed to have been connected with this ancient custom, are said by some antiquaries to be still discoverable on it. On the summit of the sacred hill, which is 512 feet above the level of the sea, is a rath called the Rath of the Synods, or the King's Chair, and at a short distance a larger rath called the King's Rath. Other raths are to be seen at Lismullen, Odder, and Ringlestoun. Columbkill's House, a stone-roofed crypt or cell at Kells, is said to be the most ancient building of that material in Ireland. The ruins of monastic buildings scattered throughout the county are too numerous to admit even of recapitulation. Trim had seven monastic institutions; Kells, Killeen, Duleek, and Skryne, three each. Several of these buildings have been converted into parish churches. The ruins of ancient castles are not less numerous. Some of them have been altered into modern residences. Of these Slane Castle, the seat of the Marquis of Conyngham, is conspicuous both for architectural structure and beautiful situation on a richly wooded elevation overhanging the Boyne. It was a favourite spot with King George IV. during his visit to Ireland in 1821. Killeen Castle, the seat of the Earl of Fingal, in addition to its claims on the score of antiquity, is memorable as having afforded an asylum during the rebellion of 1798 to the well-affected of every description. The clergymen, both Protestant and Catholic, performed divine service there under the same roof as long as danger existed.

Meaux
Mecca.

The principal towns of Meath are Navan, Kells, and Trim, the county town, none of which has a population above 4000. These towns will be found described under their respective heads. (H. S—R.)

MEAUX, a town of France, capital of an arrondissement of the same name in the department of Seine-et-Marne, is situated on the Marne, 25 miles E.N.E. of Paris. It is well built, though not very regularly laid out; and contains a fine cathedral, built in the eleventh century, and dedicated to St Etienne, but which is in an imperfect state, having only one complete tower in the front. Besides this, the principal buildings are,—the episcopal palace, a library with 13,000 volumes, a college, town-hall, and theatre. The chief articles of manufacture are,—cotton, earthenware, glue, flour, leather, and saltpetre; and the trade is considerable in grain and cheese. Meaux is an ancient city, occupying the site of *Iatinum*, the capital of the Meldi, from whom the city derives its modern name. It is, however, chiefly notable as the see of the celebrated Bossuet, who became bishop in 1681, and continued in that office till his death in 1704. His remains are deposited in the cathedral, where there is also a monument of white marble erected to his memory. When his tomb was opened in 1854, the body of the illustrious prelate was found in a very good state of preservation. Pop. (1851) 8356.

MECCA, MECCAH, or MEKKA, a city of Arabia, capital of the province of El Hejaz, is situated in a narrow valley stretching N. and S., 70 miles E. of Jiddah, its port on the Red Sea; Lat. 21. 30. N., Long. 40. 8. E. It is very closely confined between bare hills from 200 to 500 feet high, and is built in a strong and substantial manner, the principal materials being brick, granite, and sandstone quarried from the neighbouring hills. The length of the city and suburbs from N. to S. is about 2½ miles; and its broadest part is three-quarters of a mile from E. to W. Near the centre stands the famous mosque containing the Kaabah, to which Mecca owes its sanctity in the eyes of the followers of Mohammed. The densest part of the town is on the slope of the hill to the E., called Abu Kubays. Mecca was formerly walled on three sides, but is now only defended by the hills which inclose it, and by a strong square castle situated on a rising ground called Jiyad, to the S. The position of the city has been compared by Lieut. Burton to that of Bath, and by others to that of Florence, though vastly inferior to either, and especially to the latter, in beauty. The houses are in general three storeys in height; and, contrary to the usual custom in eastern towns, they have windows in front opening into the street. Most of the houses are fitted up for the accommodation of pilgrims who frequent the holy shrine at Mecca, and consist of a number of separate lodgings, each containing a sitting-room and a kitchen. On the roofs of the houses there are terraces surrounded by parapets, which conceal their occupants from view. The streets are wide, but unpaved, and in rainy weather are extremely muddy. The city is remarkably destitute of public buildings,—a fact which Burckhardt has accounted for by the reverence with which the shrine of their religion is regarded by all true Mohammedans. This building, which is called by the Moslems *Bait Ullah* (the House of Allah) or *Kaabah* (the Cube or Square House), stands in the centre of the mosque, a large open court of an irregular oblong form. Although the outer walls of the mosque are not perfectly straight, the unsymmetrical appearance of the exterior is removed by a colonnade of a more regular form which runs round the inside. The size of the mosque is, according to the measurement of Lieutenant Burton, 257 paces by 210, although most of the Moslem authorities make it considerably less. The pillars of the colonnade which are ranged along the east wall in four rows, and on the other three sides for the most part only three deep, are more than 20 feet high and about 1½ in thickness, and are crowned with capitals of Saracenic architecture, of which no two can be found exactly alike. The materials of which they are composed are white marble, granite, and sandstone. As little regard has been paid to uniformity in the arrangement of these pillars as in their substance and workmanship; it has therefore been found no easy task for visitors to ascertain their exact number, but there are probably between 550 and 600 in all. Springing from every four columns may be seen a small dome, plastered and whitewashed on the outside; and seven minarets, as well as many towers and pinnacles, are placed among the cloisters and at the corners. The number of the domes is said to be 152; and it is stated that there are in all 1352 towers and pinnacles on the walls. The minarets and several other parts of the walls and arches are painted in bright colours; but there are no representations of flowers, such as are usually to be met with in Mohammedan mosques. The floor of the cloisters is paved with large stones, and eight raised pavements of the same sort extend from the outside to the middle of the area, where stands the Kaabah. They have a sufficient breadth to allow four or five persons to walk abreast, and are raised about 9 inches above the rest of the ground; serving at once as passages to the central shrine and as partitions to separate the spaces allotted to the different classes of worshippers. Near the centre of the inclosure stands the Kaabah, an oblong edifice of fine grey granite, which, according to Burton, is 55 feet in length by 45 in breadth. Its height appeared to that traveller to exceed its length; but Burckhardt states it as between 35 and 40 feet. The ground on which it stands is slightly inclined, and the roof also has a slope, so as to allow the water to run off, but not so much as to prevent the entire building from having the general appearance of a cube, from which it derives its name. It is surrounded by a covering of black silk hanging from the roof, with a golden band running round the top, and a golden curtain in front of the door. The *Hajar el Aswad*, or Black Stone, which is the object of so much adoration on the part of pilgrims and devotees, stands at the east corner of the building, at a height of 4 or 5 feet from the ground, and is composed of a number of small stones well cemented together and carefully smoothed, presenting the appearance of having been violently broken in pieces and then mended. The constant wear which the stone has undergone from the lips and hands of the superstitious worshippers has rendered it extremely difficult to tell the nature of the material; but most travellers are agreed that it is of volcanic origin, and Lieutenant Burton expresses his conviction that it is a large aerolite. The door of the Kaabah, by which free admission is granted only ten or twelve times a year, is in the north-west side, about 7 feet from the ground, not far from the Black Stone, and is covered with silver, and adorned with ornaments of gold. There is a flight of steps of carved wood by which entrance is gained to the temple, and which is moved away on rollers and placed at a distance when not used. The interior is plain, and destitute of windows or any other opening besides the entrance, except a small door, called the *Bab el Taubah*, or Gate of Repentance, leading to a staircase by which the attendants gain access to the roof. The floor and walls consist of a sort of chequer-work of marble of various colours, principally white; and the roof and top part of the walls are covered with red damask embroidered with gold. In the roof there are three cross rafters resting on the north-eastern and south-western sides, and on three pillars in the centre. Between these, at the height of about 9 feet, there is a metal bar from which many lamps are hung; and the only other article of furniture in the apartment is a small press in one corner, in which the key of the building is some-

Mecca.

times placed. On the outside, in the south-west wall, there is a stone, distinguished from the rest by its dark red colour, which, as well as the Black Stone, is touched and kissed by the devotees. Not far from the door there is a small hollow, paved with marble, where it is reckoned an act of merit to pray, as being the place where Abraham and Ishmael are said to have kneaded the cement for building the Kaabah. It is called *El Maajan,* the Place of Mixing or Kneading. On the N.W. side of the Kaabah are said to be situated the graves of Ishmael and Hagar, inclosed by a semicircular wall 5 feet high and 4 thick, covered with white marble. Round the Kaabah is an oval inclosure, well paved with marble, and surrounded by thirty-two iron posts, connected by rods, which support many lamps, said to exceed 1000 in number. Outside of this inclosure there are two broad steps, which rise from the level of the Kaabah to that of the surrounding area. Nearly opposite to the four sides of the central building stand four *makams*—small buildings, somewhat like Indian pagodas, for the accommodation of the imams of the four orthodox sects in conducting the devotions of their adherents, who take their seats near their respective imams. One of these makams contains a stone which is said to bear the impress of Abraham's foot. The *Zem Zem,* or Sacred Well, believed to be that of Hagar, is inclosed in a square substantial building opposite the east corner of the Kaabah, and near one of the four makams. The interior of this edifice is adorned with marble of various colours, so as to have a beautiful appearance, and the well itself is surrounded by a circular wall 5 feet high and 10 in diameter. The origin of the name *Zem Zem* is doubtful; but the water is believed by the Moslems to possess great virtues, although its taste is far from pleasant, and it is apt to cause diarrhœa and boils. Jars of this water are placed in rows throughout the area of the mosque. There are two other buildings in the sacred inclosure, which stand to the north-east of the Zem Zem, and are used, the one to contain the clocks sent hither by the sultan, and the other the MSS. belonging to the mosque. These buildings are called *El Kobbateyn,* and are very heavy looking, agreeing ill with the light and elegant structure of the makams. The *mambar,* or pulpit, stands opposite to the front of the Kaabah, and is an elegant structure of white marble, ascended by a straight and narrow stair from behind, and surmounted by a gilt pinnacle in the form of an obelisk. The mosque is entered by nineteen gates, most of which have two or three arches; and as none have doors, it is open at all times. The outside walls are those of the adjoining houses, which, though originally the property of the mosque, have now fallen into the hands of private individuals, and are let to the richer pilgrims, who are allowed to perform their devotions at home, if within sight of the Kaabah.

Such is the famous mosque of Mecca; a building which is as much an object of reverence to Mohammedans as the Holy Sepulchre to Catholics, and which, like that also, has furnished the model of many other places of worship. Christians are not allowed to enter, and would incur serious danger if discovered within the pale of the sacred edifice; but this has not hindered enterprising travellers from penetrating its mysteries in the disguise of pilgrims. In this manner it has been visited by Burckhardt, Badia, and Burton, all of whom have embodied the result of their observations in pretty full accounts of the celebrities of Mecca. Besides the mosque, Mecca contains the palace of the sherif,—a large whitewashed building with wooden balconies, but in no way very remarkable. It stands in the northern suburb of the town; and not far off there is a deserted house, once the abode of the Sherif bin Aun, but now said to be haunted. The Meccans also show in the town the birthplace of the prophet, the house in which he lived, and many other localities connected with various recorded events of his life. All these places are visited by the pilgrims with great attention and respect. The cemetery of Mecca, called *Jannat el Maala,* is also much frequented by devotees, as it contains the tombs of Mohammed's mother and of his first wife, as well as those of many other Moslem saints. It is a bare piece of ground at the foot of the western hills, surrounded by a rude wall, and entered through a mean-looking gateway. About 12 miles to the E. of Mecca stands Mount Arafat, which is a place visited by all the pilgrims to Mecca, and on which certain devotions are performed, and a sermon preached to the pilgrims. It rises from a sandy and gravelly plain to the height of 180 or 200 feet; and the plain is covered during the ceremony with the tents of the pilgrims. The numbers present on these occasions are believed by the Arabs to be never less than 600,000, as there is a tradition that when they do not make up this number the angels descend to complete the assemblage. It was calculated, however, by Burton in 1853, that there were only 50,000; and in the following year the number fell to 25,000. Another place visited by pilgrims is Muna, between Arafat and Mecca, where there is a rude piece of masonry in a narrow and rugged defile. The ceremony performed here forms the concluding act of the pilgrimage: it consists of throwing small pebbles and muttering certain words, and is called *stoning the devil.* The inhabitants of Mecca are little employed in manufactures, but a considerable trade is carried on, especially during the season of pilgrimage. Pop. about 45,000.

MECHAIN, Pierre François André, a practical astronomer and geographer, was born at Laon on the 16th April 1744. His father, who was an architect, educated him for his own profession, but he accidentally became acquainted with Lalande, under whose patronage he was subsequently brought forward as an observer, surveyor, and computer. He made two voyages with M. de la Bretonnière, and assisted him in surveying some parts of the coast of France. He was afterwards employed in various computations by the Marquis de Chabert and the Duc D'Ayen. Having obtained a prize from the Academy of Sciences in 1782, for a Memoir on Comets, he became a member of the Academy the same year. About the year 1785 he undertook the publication of the *Connaissance des Tems,* and continued it till he was employed in geodetical operations at a distance from Paris. He was appointed member of a committee, along with Cassini, De Thury, and Legendre, to meet the English astronomers for the determination of the relative situation of the observatories which had been proposed by Cassini. It was in these operations that he first brought Borda's circle into general use. In 1791 he was appointed, in conjunction with Delambre, to execute the intentions of the Constituent Assembly with regard to the determination of a basis of linear measures. He was made director of the observatory of Paris, and he entered with great zeal on a series of observations which were to rival those of Flamsteed, Bradley, and Maskelyne; but he afterwards solicited the appointment to assist in the measurements required for the still farther extension of the arc of the meridian to the S. of Barcelona. But the secret motive for his seeking this humbler employment appears to have been a desire to remove some doubts which he entertained respecting the latitude of Barcelona, as it appeared after his death from his papers that there had been a discordance of 3″ in some previous observations. Shipwreck and disease awaited him, however, and he died of fever on the 20th September 1805.

Of his publications the most important are to be found in the *Mémoires des Savans étrangers;* also a Memoir on the Comets of 1532 and 1661, which gained the prize. In the Memoirs of the Academy, and in the *Connaissance des Tems,* from 1782 to 1785, there are several of his observations.

MECHANICS.

1. Mechanics, *Applicate* or *Applied*, is a term which, strictly speaking, includes all applications of the principles of abstract mechanics to human art.[1] As in other branches of knowledge, so in mechanics, art is more ancient than science, many mechanical inventions having been introduced into practice ages before the general principles of their action were discovered; but also, as in other branches of knowledge, so in mechanics, science is necessary to the perfecting of art, and mechanical inventions have in all cases continued rude, wasteful, and inefficient, until their dependence on general principles has been understood. Thus have theory and practice in all ages promoted each others' advancement; and the greatest obstacle to the advancement of both has always been a popular and scholastic fallacy that they are inconsistent. Happily that fallacy is now disappearing, and its occurrence in the writings of any author may be considered as a mark either of ignorance, or of the inconsiderate use of words.

2. *Divisions of the Subject—Structures and Machines.*—The practical applications of Mechanics may be divided into two classes, according as the assemblages of material objects to which they relate are intended to remain fixed or to move relatively to each other; the former class being comprehended under the term "Theory of Structures," and the latter under the term "Theory of Machines." As the details of the theory of structures are amply set forth in this Encyclopædia, in the articles relating to the art of Construction,—such as Aqueduct, Arch, Brickmaking, Bridge, Building, Carpentry, Centre, Dock, Drainage, Embankment, Fortification, Harbours, Iron, Iron Bridges, Joinery, Masonry, Naval Architecture, Railroads, Strength of Materials, &c.,—that theory will be treated of in the present article to such extent only as may be necessary in order to state certain general principles applicable to all these subjects. The greater part of the article will relate to machines.

PART I.—OUTLINE OF THE THEORY OF STRUCTURES.

3. *Support of Structures.*—Every structure, as a whole, is maintained in equilibrio by the joint action of its own *weight*, of the *external load* or pressure applied to it from without and tending to displace it, and of the *resistance* of the material which supports it. A structure is supported either by resting on the solid crust of the earth, as buildings do, or by floating in a fluid, as ships do in water and balloons in air. The principles of the support of a floating structure form an important part of the science of Hydrodynamics, and of the arts of Aeronautics and Naval Architecture, to the articles under which titles the reader is referred. The principles of the support, as a whole, of a structure resting on the land, are so far identical with those which regulate the equilibrium and stability of the several parts of that structure, and of which a summary will presently be given, that the only principle which seems to require special mention here is one which comprehends in one statement the power both of liquids and of loose earth to support structures, and which was first demonstrated in a paper "On the Stability of Loose Earth," read to the Royal Society on the 19th of June 1856, and published in the *Philosophical Transactions* for that year, viz.:—

Let E represent the weight of the portion of a horizontal stratum of earth which is displaced by the foundation of a structure; S the utmost weight of that structure, consistently with the power of the earth to resist displacement; ϕ the angle of repose of the earth; then

$$\frac{S}{E}=\left(\frac{1+\sin\phi}{1-\sin\phi}\right)^2.$$

To apply this to liquids, ϕ must be made $= 0$, and then $\frac{S}{E}=1$, as is well known.

4. *Composition of a Structure, and Connection of its Pieces.*—A structure is composed of *pieces*,—such as the stones of a building in masonry, the beams of a timber frame-work, the bars, plates, and bolts of an iron bridge. Those pieces are connected at their *joints* or surfaces of mutual contact, either by simple pressure and friction (as in masonry with moist mortar or without mortar); by pressure and adhesion (as in masonry with cement or with hardened mortar, and timber with glue); or by the resistance of *fastenings* of different kinds, whether made by means of the form of the joint (as dovetails, notches, mortises and tenons); or by separate fastening pieces (as trenails, pins, spikes, nails, holdfasts, screws, bolts, rivets, hoops, straps, and sockets).

5. *Stability, Stiffness, and Strength.*—A structure may be damaged or destroyed in three ways,—first, by *displacement* of its pieces from their proper positions relatively to each other or to the earth; secondly, by *disfigurement* of one or more of those pieces, owing to their being unable to preserve their proper shapes under the pressures to which they are subjected; thirdly, by *breaking* of one or more of those pieces. The power of resisting displacement constitutes *stability;* the power of each piece to resist disfigurement is its *stiffness;* and its power to resist breaking, its *strength.*

6. *Conditions of Stability.*—The principles of the stability of a structure can be to a certain extent investigated independently of the stiffness and strength, by assuming, in the first instance, that each piece has strength sufficient to be safe against being broken, and stiffness sufficient to prevent its being disfigured to an extent inconsistent with the purposes of the structure, by the greatest forces which are to be applied to it. The condition that each piece of the structure is to be maintained in equilibrio by having its gross load, consisting of its own weight and of the external pressure applied to it, balanced by the *resistances* or pressures exerted between it and the contiguous pieces, furnishes the means of determining the magnitude, position, and direction of the resistances required at each joint in order to produce equilibrium; and the *conditions of stability* are, first, that the *position*, and secondly, that the *direction*, of the resistance required at each joint shall, under all the variations to which the load is subject, be such as the joint is capable of exerting,—conditions which are fulfilled by suitably adjusting the figures and positions of the joints, and the *ratios* of the gross loads of the pieces. As for the *magnitude* of the resistance, it is limited by conditions, not of stability, but of strength and stiffness.

7. *Principle of Least Resistance.*—Where more than one system of resistances are alike capable of balancing the same system of loads applied to a given structure, it has been demonstrated by Mr Moseley, that the *smallest* of those alternative systems is that which will actually be ex-

---

[1] For the exposition of the principles of abstract mechanics, see the articles Dynamics and Statics.

erted;[1] because the resistances to displacement are the effect of a strained state of the pieces, which strained state is the effect of the load, and when the load is applied the strained state and the resistances produced by it increase until the resistances acquire just those magnitudes which are sufficient to balance the load, after which they increase no further.

This "principle of least resistance" renders determinate many problems in the statics of structures which were formerly considered indeterminate.

8. *Relations between Polygons of Loads and of Resistances.*—In a structure in which each piece is supported at two joints only, the well-known laws of statics show that the directions of the gross load on each piece, and of the two resistances by which it is supported, must lie in one plane,—must either be parallel, or meet in one point,—and must bear to each other, if not parallel, the proportions of the sides of a triangle respectively parallel to their directions; and if parallel, such proportions that each of the three forces shall be proportional to the distance between the other two; all the three distances being measured along one direction.

Considering, in the first place, the case in which the load and the two resistances by which each piece is balanced meet in one point, which may be called the *centre of load*, there will be as many such points of intersection, or centres of load, as there are pieces in the structure; and the directions and positions of the resistances or mutual pressures exerted between the pieces will be represented by the sides of a polygon joining those points, as in fig. 1, where P_1, P_2, P_3, P_4, represent the centres of load in a structure of four pieces; and the sides of the *polygon of resistances* $P_1P_2P_3P_4$ represent respectively the directions and positions of the resistances exerted at the joints. Further, at any one of the centres of load let PL represent the magnitude and direction of the gross load, and P*a*, P*b* the two resistances by which the piece to which that load is applied is supported; then will those three lines be respectively the diagonal and sides of a parallelogram; or, what is the same thing, they will be equal to the three sides of a triangle; and they must be in the same plane, although the sides of the polygon of resistances may be in different planes.

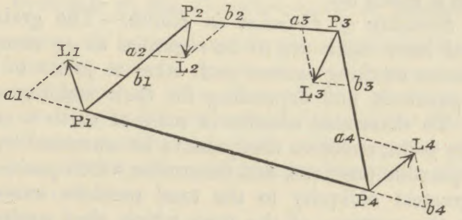

Fig. 1.

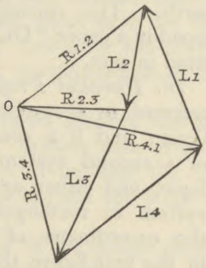

Fig. 2.

According to a well-known principle of statics, because the loads or external pressures P_1L_1, &c., balance each other, they must be proportional to the sides of a closed polygon drawn respectively parallel to their directions. In fig. 2 construct such a *polygon of loads* by drawing the lines L_1, &c., parallel and proportional to, and joined end to end in the order of, the gross loads on the pieces of the structure. Then from the proportionality and parallelism of the load, and the two resistances applied to each piece of the structure, to the three sides of a triangle, there results the following—

THEOREM.—*If from the angles of the polygon of loads there be drawn lines* ($R_{1,2}$, &c.), *each of which is parallel to the resistance* (as P_1P_2, &c.) *exerted at the joint between the pieces to which the two loads represented by the contiguous sides of the polygon of loads* (such as L_1, L_2, &c.) *are applied; then will all those lines meet in one point* (O), *and their lengths, measured from that point to the angles of the polygon, will represent the magnitudes of the resistances to which they are respectively parallel.*

(The particular case of this theorem which relates to a system of parallel vertical loads, has long been known; but in its general form the theorem is now published in type for the first time, having appeared originally in a lithographed abstract of some lectures.)

When the load on one of the pieces is parallel to the resistances which balance it, the polygon of resistances ceases to be closed, two of the sides becoming parallel to each other and to the load in question, and extending indefinitely. In the polygon of loads the direction of a load sustained by parallel resistances traverses the point O.

9. *How the Earth's Resistance is to be treated.*—When the pressure exerted by a structure on the earth (to which the earth's resistance is equal and opposite) consists either of one pressure, which is necessarily the resultant of the weight of the structure and of all the other forces applied to it, or of two or more parallel vertical forces, whose amount can be determined at the outset of the investigation, the resistance of the earth can be treated as one or more *upward loads* applied to the structure. But in other cases the earth is to be treated as *one of the pieces of the structure*, loaded with a force equal and opposite in direction and position to the resultant of the weight of the structure and of the other pressures applied to it.

10. *Partial Polygons of Resistance.*—In a structure in which there are pieces supported at more than two joints, let a polygon be constructed of lines connecting the centres of load of any continuous series of pieces. This may be called a *partial polygon of resistances.* In considering its properties, the *load* at each centre of load is to be held to *include* the resistances of those joints which are *not* comprehended in the partial polygon of resistances, to which the theorem of section 8 will then apply in every respect. By constructing several partial polygons, and computing the relations between the loads and resistances which are determined by the application of that theorem to each of them, with the aid, if necessary, of Mr Moseley's principle of the least resistance, the whole of the relations amongst the loads and resistances may be found.

11. *Line of Pressures—Centres and Line of Resistance.*—The *line of pressures* is a line to which the directions of all the resistances in one polygon are tangents. The *centre of resistance* at any joint is the point where the line representing the total resistance exerted at that joint intersects the joint. The *line of resistance* is a line traversing all the centres of resistance of a series of joints; its form, in the positions intermediate between the actual joints of the structure, being determined by supposing the pieces and their loads to be subdivided by the introduction of intermediate joints *ad infinitum*, and finding the continuous line, curved or straight, in which the intermediate centres of resistance are all situated, how great soever their number. The difference between the line of resistance and the line of pressures was first pointed out by Mr Moseley.

12. *Stability of Position, and Stability of Friction.*—The resistances at the several joints having been determined by the principles set forth in sections 7, 8, 9, 10, and 11, not only under the ordinary load of the structure, but

---

[1] *Mechanics of Engineering and Architecture*, by the Rev. Henry Moseley.

under all the variations to which the load is subject as to amount and distribution, the joints are now to be placed and shaped so that the pieces shall not suffer relative displacement under any of those loads. The relative displacement of the two pieces which abut against each other at a joint may take place either by turning or by sliding. Safety against displacement by turning is called *stability of position;* safety against displacement by sliding, *stability of friction.*

13. *Condition of Stability of Position.*—If the materials of a structure were infinitely stiff and strong, stability of position at any joint would be insured simply by making the centre of resistance fall within the joint under all possible variations of load. In order to allow for the finite stiffness and strength of materials, the least distance of the centre of resistance inward from the nearest edge of the joint is made to bear a definite proportion to the depth of the joint measured in the same direction, which proportion is fixed, sometimes empirically, sometimes by theoretical deduction from the laws of the strength of materials. That least distance is called by Mr Moseley the *modulus of stability.* The following are some of the ratios of the modulus of stability to the depth of the joint which occur in practice:—

Retaining walls, as designed by British engineers	$\frac{1}{8}$
Retaining walls, as designed by French engineers	$\frac{1}{5}$
Rectangular piers of bridges and other buildings, and arch-stones	$\frac{1}{3}$
Rectangular foundations, firm ground	$\frac{1}{3}$
Rectangular foundations, very soft ground	$\frac{1}{2}$
Rectangular foundations, intermediate kinds of ground	$\frac{1}{3}$ to $\frac{1}{2}$
Thin, hollow towers (such as furnace chimneys exposed to high winds), square	$\frac{1}{6}$
Thin, hollow towers, circular	$\frac{1}{4}$

(In the last two cases, the *depth of the joint* is to be understood to mean the *diameter of the tower.*)

Frames of timber or metal, under their ordinary or average distribution of load	$\frac{1}{2}$
Frames of timber or metal, under the greatest irregularities of load	$\frac{1}{3}$

14. *Condition of Stability of Friction.*—If the resistance to be exerted at a joint is always perpendicular to the surfaces which abut at and form that joint, there is no tendency of the pieces to be displaced by sliding. If the resistance be oblique, let JK (fig. 3) be the joint; C its centre of resistance; CR a line representing the resistance; CN a perpendicular to the joint at the centre of resistance. The angle NCR is the *obliquity* of the resistance. From R draw RP parallel and RQ perpendicular to the joint; then by the principles of statics, the component of the resistance *normal* to the joint is—

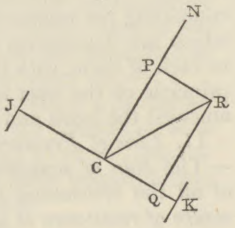

Fig. 3.

$$\overline{CP}=\overline{CR}\cdot\cos\angle PCR;$$

and the component *tangential* to the joint is—

$$\overline{CQ}=CR\cdot\sin\angle PCR=\overline{CP}\cdot\tan\angle PCR.$$

If the joint be provided either with projections and recesses, such as mortises and tenons, or with fastenings, such as pins or bolts, so as to resist displacement by sliding, the question of the utmost amount of the tangential resistance $\overline{CQ}$ which it is capable of exerting depends on the *strength* of such projections, recesses, or fastenings, and belongs to the subject of strength, and not to that of stability. In other cases the safety of the joint against displacement by sliding depends on its power of exerting friction, and that power depends on the law, known by experiment, that the friction between two surfaces bears a constant ratio, depending on the nature of the surfaces, to the force by which they are pressed together. In order that the surfaces which abut at the joint JK may be pressed together, the resistance required by the conditions of equilibrium, $\overline{CR}$, must be a *thrust* and not a *pull;* and in that case the force by which the surfaces are pressed together is equal and opposite to the normal component $\overline{CP}$ of the resistance. The condition of stability of friction is, that the tangential component $\overline{CQ}$ of the resistance required shall not exceed the friction due to the normal component; that is, that

$$\overline{CQ}\leqq f\cdot\overline{CP}$$

where f denotes the *coefficient of friction* for the surfaces in question. The angle whose tangent is the coefficient of friction is called *the angle of repose,* and is expressed symbolically by—

$$\varphi=\text{arc}\cdot\tan f.$$

$$\text{Now }\overline{CQ}=\overline{CP}\cdot\tan\angle PCR;$$

consequently the condition of stability of friction is fulfilled if

$$\angle PCR\leqq\phi;$$

that is to say, if *the obliquity of the resistance required at the joint does not exceed the angle of repose;* and this condition ought to be fulfilled under all possible variations of the load.

It is chiefly in masonry and earthwork that stability of friction is relied on.

15. *Stability of Friction in Earth.*—The grains of a mass of loose earth are to be regarded as so many separate pieces abutting against each other at joints in all possible positions, and depending for their stability on friction. To determine whether a mass of earth is stable at a given point, conceive that point to be traversed by planes in all possible positions, and determine which position gives the greatest obliquity to the total pressure exerted between the portions of the mass which abut against each other at the plane. The condition of stability is, that this obliquity shall not exceed the angle of repose of the earth. The consequences of this principle are developed in a paper "On the Stability of Loose Earth," already cited in sect. 3.

16. *Parallel Projections of Figures.*—If any figure be referred to a system of co-ordinates, rectangular or oblique; and if a second figure be constructed by means of a second system of co-ordinates, rectangular or oblique, and either agreeing with or differing from the first system in rectangularity or obliquity, but so related to the co-ordinates of the first figure that for each point in the first figure there shall be a corresponding point in the second figure, the lengths of whose co-ordinates shall bear, respectively, to the three corresponding co-ordinates of the corresponding point in the first figure, three ratios which are the same for every pair of corresponding points in the two figures; that pair of figures are called *parallel projections* of each other. The properties of parallel projections of most importance to the subject of the present article are the following:—

(1.) A parallel projection of a straight line is a straight line.

(2.) A parallel projection of a plane is a plane.

(3.) A parallel projection of a straight line or a plane surface divided in a given ratio, is a straight line or a plane surface divided in the same ratio.

(4.) A parallel projection of a pair of equal and parallel straight lines, or plain surfaces, is a pair of equal and parallel straight lines, or plane surfaces, whence it follows:—

(5.) That a parallel projection of a parallelogram is a parallelogram;—

(6.) That a parallel projection of a parallelopiped is a parallelopiped.

(7.) A parallel projection of a pair of solids having a given ratio is a pair of solids having the same ratio.

Though not essential for the purposes of the present article, the following consequence will serve to illustrate the principle of parallel projections :—

(8.) A parallel projection of a curve, or of a surface of a given algebraical order, is a curve, or a surface of the same order.

For example, all ellipsoids referred to co-ordinates parallel to any three conjugate diameters are parallel projections of each other, and of a sphere referred to rectangular co-ordinates.

17. *Parallel Projections of Systems of Forces.*—If a balanced system of forces be represented by a system of lines, then will every parallel projection of that system of lines represent a balanced system of forces.

For the condition of equilibrium of forces not parallel is, that they shall be represented in direction and magnitude by the sides and diagonals of certain parallelograms ;—and of parallel forces, that they shall divide certain straight lines in certain ratios ; and the parallel projection of a parallelogram is a parallelogram, and that of a straight line divided in a given ratio, is a straight line divided in the same ratio.

The resultant of a parallel projection of any system of forces is the projection of their resultant ; and the centre of gravity of a parallel projection of a solid is the projection of the centre of gravity of the first solid.

18. *Principle of the Transformation of Structures.*—

> Theorem.—If a structure of a given figure have stability of position under a system of forces represented by a given system of lines, then will any structure, whose figure is a parallel projection of that of the first structure, have stability of position under a system of forces represented by the corresponding projection of the first system of lines.

For in the second structure the weights, external pressures, and resistances, will balance each other as in the first structure ; the weights of the pieces, and all other parallel systems of forces, will have the same ratios as in the first structure ; and the several centres of resistance will divide the depths of the joints in the same proportions as in the first structure.

If the first structure have stability of friction, the second structure will have stability of friction also, so long as the effect of the projection is not to increase the obliquity of the resistance at any joint beyond the angle of repose.

The lines representing the forces in the second figure show their *relative* directions and magnitudes. To find their *absolute* directions and magnitudes, a vertical line is to be drawn in the first figure, of such a length as to represent the weight of a particular portion of the structure. Then will the projection of that line in the projected figure indicate the vertical direction, and represent the weight of the part of the second structure corresponding to the before-mentioned portion of the first structure.

The foregoing "principle of the transformation of structures" was first announced, though in a somewhat less comprehensive form, to the Royal Society on the 6th of March 1856. It is here published in its most general form for the first time in type, having previously appeared only in the lithographed abstract of some lectures. It is useful in practice, by enabling the engineer easily to deduce the conditions of equilibrium and stability of structures of complex and unsymmetrical figures from those of structures of simple and symmetrical figures. By its aid, for example, the whole of the properties of elliptical arches, whether square or skew, whether level or sloping in their span, are at once deduced by projection from those of symmetrical circular arches, and the properties of ellipsoidal and elliptic-conoidal domes from those of hemispherical and circular-conoidal domes ; and the figures of arches fitted to resist the thrust of earth, which is less horizontally than vertically in a certain given ratio, can be deduced by projection from those of arches fitted to resist the thrust of a liquid, which is of equal intensity, horizontally and vertically.

19. *Conditions of Stiffness and Strength.*—After the arrangement of the pieces of a structure, and the size and figure of their joints or surfaces of contact have been determined so as to fulfil the conditions of *stability*,—conditions which depend mainly on the position and direction of the *resultant* or *total* load on each piece, and the *relative* magnitude of the loads on the different pieces,—the dimensions of each piece singly have to be adjusted so as to fulfil the conditions of *stiffness* and *strength*,—conditions which depend not only on the *absolute* magnitude of the load on each piece, and of the resistances by which it is balanced, but also on the *mode of distribution* of the load over the piece, and of the resistances over the joints.

The effect of the pressures applied to a piece, consisting of the load and the supporting resistances, is to force the piece into a state of *strain* or disfigurement, which increases until the elasticity, or resistance to strain, of the material causes it to exert a *stress*, or effort to recover its figure, equal and opposite to the system of applied pressures. The condition of *stiffness* is, that the strain or disfigurement shall not be greater than is consistent with the purposes of the structure ; and the condition of *strength* is, that the stress shall be within the limits of that which the material can bear with safety against breaking. The ratio in which the utmost stress before breaking exceeds the safe working stress is called the *factor of safety*, and is determined empirically. It varies from three to twelve for various materials and structures.

The Strength of Materials forms the subject of a special article, to which the reader is now referred.

PART II.—THEORY OF MACHINES.

20.—*Parts of a Machine—Frame and Mechanism.*—The parts of a machine may be distinguished into two principal divisions,—the *frame*, or fixed parts, and the *mechanism*, or moving parts. The frame is a structure which supports the pieces of the mechanism, and to a certain extent determines the nature of their motions. The form and arrangement of the pieces of the frame depend upon the arrangement and the motions of the mechanism ; the dimensions of the pieces of the frame required in order to give it stability and strength, are determined from the pressures applied to it by means of the mechanism. It appears, therefore, that in general the mechanism is to be designed first and the frame afterwards, and that the designing of the frame is regulated by the principles of the stability of structures and of the strength and stiffness of materials ; care being taken to adapt the frame to the most severe load which can be thrown upon it at any period of the action of the mechanism.

Each independent piece of the mechanism also is a structure, and its dimensions are to be adapted, according to the principles of the strength and stiffness of materials, to the most severe load to which it can be subjected during the action of the machine.

21. *Definition and Division of the Theory of Machines.*—From what has been said in the last section, it appears that the department of the art of designing machines which has reference to the stability of the frame, and to the stiffness and strength of the frame and mechanism, is a branch of the art of construction. It is therefore to be separated from the *theory of machines*, properly speaking, which has

reference to the action of machines considered as moving. In the action of a machine the following three things take place:—

First, Some natural source of energy communicates motion and force to a piece or pieces of the mechanism, called the *receiver of power*, or *prime mover*.

Secondly, The motion and force are transmitted from the prime mover through the *train of mechanism* to the *working piece or pieces*, and during that transmission the motion and force are modified in amount and direction, so as to be rendered suitable for the purpose to which they are to be applied.

Thirdly, The working piece or pieces, by their motion, or by their motion and force combined, produce some useful effect.

Such are the phenomena of the action of a machine, arranged in the order of *causation*. But in studying or treating of the theory of machines, the order of *simplicity* is the best; and in this order the first branch of the subject is the modification of motion and force by the train of mechanism; the next is the effect or purpose of the machine; and the last, or most complex, is the action of the prime mover.

The modification of motion and the modification of force take place together, and are connected by certain laws; but in the study of the theory of machines, as well as in that of pure mechanics, much advantage has been gained in point of clearness and simplicity by first considering alone the principles of the modification of motion, which are founded upon a branch of geometry called Cinematics, and afterwards considering the principles of the combined modification of motion and force, which are founded both on geometry and on the laws of dynamics. The separation of Cinematics from Dynamics is due mainly to Monge, Ampère, and Professor Willis.

The theory of machines in the present article will be considered under the following four heads:—

I. PURE MECHANISM, or APPLIED CINEMATICS; being the theory of machines considered simply as modifying motion.
II. APPLIED DYNAMICS; being the theory of machines considered as modifying both motion and force.
III. PURPOSES AND EFFECTS OF MACHINES.
IV. APPLIED ENERGETICS; being the theory of prime movers and sources of power.

CHAP. I.—ON PURE MECHANISM.

22. *Division of the subject.*—Proceeding in the order of simplicity, the subject of Pure Mechanism, or Applied Cinematics, may be thus divided:—

Division 1. Motion of a point.
Division 2. Motion of the surface of a fluid.
Division 3. Motion of a rigid solid.
Division 4. Motions of a pair of connected pieces, or of an "*elementary combination*" in mechanism.
Division 5. Motions of *trains* of pieces of mechanism.
Division 6. Motions of sets of more than two connected pieces, or of "*aggregate combinations*."

A point is the boundary of a line, which is the boundary of a surface, which is the boundary of a volume. Points, lines, and surfaces have no independent existence, and consequently those divisions of this chapter which relate to their motions are only preliminary to the subsequent divisions, which relate to the motions of bodies.

DIVISION I.—MOTION OF A POINT.

23. *Path and Direction.*—The motion of a point is the change of its place relatively to some portion of space, which for the time is considered as fixed. In the theory of machines, the portion of space which is considered as fixed is usually that which is occupied by the frame of the machine. A moving point traces in the fixed space a line called its *path*, which may be straight or curved. The *direction* of the motion of the point at any instant is that of a tangent to the path drawn forwards from the position of the point at the instant in question, and is uniform if the path is straight—variable if it is curved.

24. *Uniform Velocity.*—The *velocity* or *speed* of a moving point is the length of the portion of its path which it traces in some given portion or unit of time. In calculations respecting dynamical questions, the unit of time commonly employed is the *second;* in considering the *purposes* of machines, the *minute*, the *hour*, and the *day* are also employed. When not otherwise specified, the *second* is the unit of time employed in this article. When a point continues always to trace equal lengths of its path in equal times, its velocity is said to be *uniform*, and is expressed numerically by dividing the length of any portion whatsoever of the path of the point by the time occupied by the point in tracing it. The unit of length employed in Britain to express velocities is usually the foot, but in some cases the mile. In the present article the foot is employed, where not otherwise specified; so that velocities will generally be stated in *feet per second.*

25. *Varied Velocity.*—When a moving point does not trace equal lengths of its path in equal times, its velocity is said to be *varied.* In this case it is no longer possible to compute the velocity simply by dividing the length traced between two given instants by the time occupied in tracing it, because such a computation gives different results for different pairs of instants: it gives, not the *exact* velocity at a particular instant, but the *mean* velocity between the pair of instants.

For example, let A, B denote a pair of instants of time, Δt the interval of time between them, Δs the length of path traced by the moving point in that interval, then is $\frac{\Delta s}{\Delta t}$ the *mean velocity* in the interval between A and B.

Now let C denote an instant of time anywhere between A and B, and let it be required to find the *exact* velocity of the moving point at the instant C. $\frac{\Delta s}{\Delta t}$ will be an *approximation* to that velocity. To find a closer approximation, take two instants A′ and B′, nearer to C than A and B are; let $\Delta t'$ be the interval of time, and $\Delta s'$ the length traced between A′ and B′; then will $\frac{\Delta s'}{\Delta t'}$ be a closer approximation than $\frac{\Delta s}{\Delta t}$. Having obtained a series of such approximations,

$$\frac{\Delta s}{\Delta t}, \frac{\Delta s'}{\Delta t'}, \frac{\Delta s''}{\Delta t''}, \text{\&c.},$$

by taking pairs of instants continually nearer and nearer to C, compare their results; it will be found that they follow some *law*, and that each of the mean velocities denoted above consists of a *constant part*, and of a *variable part* which continually diminishes and approximates to nothing as Δt grows smaller; that is to say, as A and B approximate to C. The constant part of the mean velocity, being the *limit* towards which $\frac{\Delta s}{\Delta t}$ approximates as Δt diminishes, is the *exact* velocity at the instant C, and is thus denoted,—

$$v = \frac{ds}{dt} \quad \ldots \ldots \quad (1.)$$

The process above described is well known in the differential calculus by the name of *differentiation;* that is to say, *finding the rate of variation* of one quantity s as compared with that of another quantity t.

In order to distinguish between motions in two opposite directions along the same path, one of those directions is called *forward*, and treated as *positive* in algebra; while the other is called *backward*, and treated as *negative*. Thus, let n denote a certain number of feet per second; then

$$v=\frac{ds}{dt}=n, \text{ or } +n,$$

will express that the velocity of the moving point is n feet per second *forwards;* and

$$v=\frac{ds}{dt}=-n$$

will express that the velocity is of equal magnitude, but *backward.*

26. *Direct Deviation, or Acceleration and Retardation.*—When the *motion* of a point is said to be *uniform*, without further qualification, it is to be understood to be uniform both in velocity and in direction.

The word *deviation* in its general sense denotes the amount of any departure from uniformity of motion, whether of velocity or of direction; and the *rate* at which any deviation takes place is ascertained by differentiation.

The rate of direct deviation is the rate at which the velocity varies, and is denoted by

$$\frac{dv}{dt}=\frac{d^2s}{dt^2}, \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad (2.)$$

being deduced from the changes of velocity in different intervals of time in the same way that the velocity is deduced from the changes of position; that is, by differentiation. Direct deviation is *acceleration* if the velocity is increased, *retardation* if it is diminished; it is *positive* if forward velocity is increased, or backward velocity diminished; *negative* if forward velocity is diminished, or backward velocity increased.

27. *Lateral Deviation or Deflection—Angular Velocity of Deviation—Revolution.*—The rate of lateral deviation, being the rate at which the moving point swerves from a straight course, is found for any instant by multiplying the velocity of the moving point by the rate at which the angular direction of its path varies. Symbolically, let θ denote the angle (expressed in length of arc to radius unity) which at any instant the path of the point makes with some fixed direction in the plane in which, for the instant, the deflection takes place; then $\frac{d\theta}{dt}$, found as before, is the rate at which the angular direction of the path varies. Let ρ denote the *radius of curvature* of the path at the instant in question; then, by the geometry of curves, it is known that

$$\frac{d\theta}{ds}=\frac{1}{\rho};$$

consequently,

$$\frac{d\theta}{dt}=\frac{ds}{\rho dt}=\frac{v}{\rho},$$

and the *rate of lateral deviation* is expressed by

$$v\frac{d\theta}{dt}=\frac{v^2}{\rho}=\rho\left(\frac{d\theta}{dt}\right)^2 \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad (3.)$$

Lateral deviation is considered as positive or negative, according to arbitrary arrangements respecting the sign of the radius of curvature of the path.

The quantity above represented by $\frac{d\theta}{dt}$ is sometimes called the *angular velocity of deviation.*

A point whose path deviates continually until it returns to its primitive direction is said to *revolve;* and the *mean angular velocity of revolution* is the circumference of a circle of the radius unity, divided by the time of one revolution.

28. *Comparative Motion.*—The comparative motion of two points is the relation which exists between their motions, without having regard to their absolute amounts. It consists of two elements,—the *velocity ratio*, which is the ratio of any two magnitudes bearing to each other the proportions of the respective velocities of the two points at a given instant; and the *directional relation*, which is the relation borne to each other by the respective directions of the motions of the two points at the same given instant.

It is obvious that the motions of a pair of points may be varied in any manner, whether by direct or by lateral deviation, and yet that their *comparative motion* may remain constant, in consequence of the deviations taking place in the same proportions, in the same directions, and at the same instants for both points.

Mr Willis has the merit of having been the first to simplify considerably the theory of pure mechanism, by pointing out that that branch of mechanics relates wholly to comparative motions.

The comparative motion of two points at a given instant is capable of being completely expressed by one of Sir William Hamilton's Quaternions,—the "Tensor" expressing the velocity-ratio, and the "Versor" the directional relation.

29. *Resolution and Composition of Motion.*—Let OPQ be part of the path of a moving point, and P the position of that point at any given instant. Let OX, OY, OZ, be any three *axes*, or fixed directions, traversing a fixed point O called the *origin.* Let three points, P_x, P_y, P_z, start from O at the same instant with P, moving respectively along the straight paths OX, OY, OZ, in such a manner that at each instant

$$OP_x=x, \qquad OP_y=y, \qquad OP_z=z,$$

shall be respectively equal to

$$PA, \qquad PB, \qquad PC,$$

the respective distances of P from the *co-ordinate planes,*

$$YOZ, \qquad ZOX, \qquad XOY,$$

measured respectively in directions parallel to the three axes,

$$OX, \qquad OY, \qquad OZ.$$

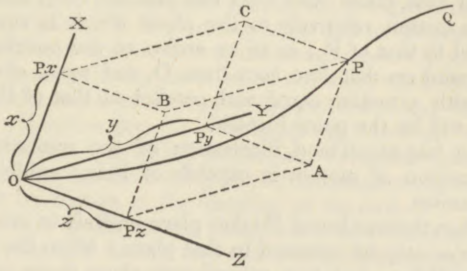

Fig. 4.

Then are P_x, P_y, P_z, called the *projections* of P on the three axes respectively; their motions are called the *components* of the motion of P parallel to the three axes; and the operation of determining those component motions is called the *resolution* of the motion of P relatively to the three axes. The operation of determining the motion of P, when its components are given, is called the *composition* of those components; and the motion of P is called the *resultant* of the motions of its projections. The following propositions are the main principles of the composition and resolution of motion:—

(1.) The straight line joining P and O is the diagonal of the parallelopiped $OP_xP_yP_zABCP$, of which x, y, z, are the edges.

(2.) If a straight line be drawn representing in direction and magnitude the velocity $v=\frac{ds}{dt}$ of P at any instant, that straight line will be the diagonal of the parallelopiped whose edges respectively represent in direction and magnitude the component velocities of P_x, P_y, and P_z; viz.,

$$\frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt}.$$

(3.) If the three respective motions of P_x, P_y, P_z, during one and the same interval of time, be determined, and if a moving point, starting from O, be made to perform in three consecutive intervals of time, motions equal and parallel to those three motions respectively, in any order of succession, then will the last-mentioned point arrive at the position occupied by P at the end of the first-mentioned interval of time.

(The path of the last-mentioned point may be any one of the six routes from O to P along the edges of the parallelopiped.)

(4.) If a plane always parallel to one of the co-ordinate planes (such as YOZ) be made to start from O at the same instant with P, and to move with the same motion as the projection of P on one of the axes (such as P_x); and if a line in that moving plane, always parallel to another of the axes (such as OZ), be made to start from O, and move *relatively* to that plane with a motion parallel and equal to that of the projection of P on the remaining axis (such as P_y); and if a point in that moving line be made to start from O, and move along that line with a motion parallel and equal to that of the third projection of P (such as P_z); then will this moving point coincide at every instant with P itself.

For example, let a plane start from the position AP_yOP_z and move along with P_x to the position PBP_xC; let a line in that plane start from the position OP_z, and move with a motion relatively to the plane which is equal and parallel to that of P_y, so as to arrive at the position CP; let a point on that line start from O, and move along the line with a motion equal and parallel to that of P_z; that point will be the point P itself.

The last-mentioned illustration of the resolution and composition of motion is capable of being exhibited by mechanism.

When the motion of P takes place entirely in one plane, two axes may be assumed in that plane; when the motion of P will have but two components along those two axes respectively, and the parallelopiped will be reduced to a parallelogram.

30. *Rectangular Projection, Resolution, and Composition.*—The choice of the three or two axes is a matter of convenience. When there is no special reason for making them oblique, they are made perpendicular to each other, or *rectangular;* and when obliquity of the axes is not specified, rectangularity is to be understood. In this case the projection of a moving point upon any one of the axes is found by letting fall a perpendicular from the point on that axis.

Let $\overline{\mathrm{OP}} = r$ denote the distance of the point from the origin at any given instant, and $\widehat{xr} = \angle \mathrm{XOP}$, the angle which that distance makes with any given axis; then for rectangular projection,

$$x = \overline{\mathrm{OP}}_x = r.\cos \widehat{xr} \quad . \quad . \quad . \quad . \quad (4.)$$

Also let v be the velocity of P at any given instant, and $\widehat{xv}$ the angle which the direction of its motion, or tangent to its path, makes at the same instant with the direction of OX; then the velocity of the rectangular projection P_x at the same instant is

$$\frac{dx}{dt} = v.\cos \widehat{xv} \quad . \quad . \quad . \quad . \quad (5.)$$

Adopting an analogous notation for other two rectangular axes, we have—

$$\left.\begin{array}{c} \cos^2 \widehat{xr} + \cos^2 \widehat{yr} + \cos^2 \widehat{zr} = 1; \\ \cos^2 \widehat{xv} + \cos^2 \widehat{yv} + \cos^2 \widehat{zv} = 1; \\ x^2 + y^2 + z^2 = r^2; \\ \left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2 = v^2. \end{array}\right\} \quad . \quad (6.)$$

31. *Resolution and Composition of Deviations.*—As the three projections of a moving point move in straight lines, their rates of deviation, if any, are wholly direct, and are represented by

$$\frac{d^2x}{dt^2}; \qquad \frac{d^2y}{dt^2}; \qquad \frac{d^2z}{dt^2}.$$

If three lines be drawn representing those three rates of deviation in direction and magnitude, the diagonal of the parallelopiped of which they are the edges is the *total* or *resultant* rate of deviation, and is the same in magnitude and direction with the diagonal of a rectangular parallelogram one of whose sides is parallel to the direction of motion of P, and represents in magnitude its rate of direct deviation $\frac{d^2s}{dt^2} = \frac{dv}{dt}$, while the other is drawn in the direction of the radius of curvature of the path of P, and represents in magnitude its rate of lateral deviation $\frac{v^3}{\rho}$. This is easily verified by the aid of well-known formulæ of the geometry of curved lines. If the motion of a point be uniform both in velocity and in direction, the components of that motion are uniform also; but if the motion of the point be deviated either in velocity or in direction, or in both, the components are deviated in velocity.

DIVISION II.—MOTION OF THE SURFACE OF A FLUID MASS.

32. *General Principle.*—A mass of fluid is used in mechanism to transmit motion and force between two or more moveable portions (called *pistons* or *plungers*) of the solid envelope or vessel in which the fluid is contained; and when such transmission is the sole action, or the only appreciable action of the fluid mass, its volume is either absolutely constant, by reason of its temperature and pressure being maintained constant, or not sensibly varied.

Let a represent the area of the section of a piston made by a plane perpendicular to its direction of motion, and v its velocity, which is to be considered as positive when outward, and negative when inward. Then the variation of the cubic contents of the vessel in a unit of time by reason of the motion of one piston is va. The condition that the volume of the fluid mass shall remain unchanged, requires that there shall be more than one piston, and that the velocities and areas of the pistons shall be connected by the equation

$$\Sigma . va = 0 \quad . \quad . \quad . \quad . \quad (7.)$$

33. *Comparative Motion of two Pistons.*—If there be but two pistons whose areas are a_1 and a_2, and their velocities v_1 and v_2, their comparative motion is expressed by the equation—

$$\frac{v_2}{v_1} = -\frac{a_1}{a_2}; \qquad . \qquad (8.)$$

that is to say, their velocities are opposite as to inwardness and outwardness, and inversely proportional to their areas.

34. *Applications: Hydraulic Press—Pneumatic Power-Transmitter.*—In the Hydraulic Press the vessel consists of two cylinders, viz., the pump-barrel and the press-barrel, each having its piston, and of a passage connecting them having a valve opening towards the press-barrel. The action of the inclosed water in transmitting motion takes place during the inward stroke of the pump-plunger, when the above-mentioned valve is open; and at that time the press-plunger moves outwards with a velocity which is less than the inward velocity of the pump-plunger, in the same ratio that the area of the pump-plunger is less than the area of the press-plunger. (For details respecting this machine, &c., see HYDRODYNAMICS.)

In the Pneumatic Power-Transmitter the motion of one piston is transmitted to another at a distance by means of a mass of air contained in two cylinders and an intervening tube. When the pressure and temperature of the air can be maintained constant, this machine fulfils equation 8, like the hydraulic press. The amount and effect of the variations of pressure and temperature undergone by the air depend on the principles of the mechanical action of heat, or *Thermodynamics*, and are foreign to the subject of pure mechanism.

DIVISION III.—MOTION OF A RIGID SOLID.

35. *Motions Classed: Shifting and Turning.*—In problems of mechanism, each solid piece of the machine is supposed to be so stiff and strong as not to undergo any sensible change of figure or dimensions by the forces applied to it; a supposition which is realized in practice if the machine is skilfully designed.

This being the case, the various possible motions of a rigid solid body may all be classed under the following heads:—

(1.) *Shifting* or *Translation*, when every point in the body has the same motion at the same instant, and when consequently no point in the body has any motion relatively to another.

(2.) *Turning* or *Rotation*, being the only kind of relative motion amongst the points of a body which is possible without change of dimensions or figure.

(3.) Motions compounded of shifting and turning.

36. *Shifting or Translation.*—In a motion of simple shifting or translation all the points of the body are moving with the same velocity, and in the same direction, at the same instant. The path of a given point may be a line of any figure—straight, curved, or angular; and the path of every other point will be a line of the same figure and dimensions. Every plane and every straight line fixed in the body moves parallel to itself.

The *relative* motion of any two points is null; that is to say, the line joining them alters neither in length nor in direction.

The *comparative* motion of any two points is expressed by the ratio of equality between their velocities, and the relation of parallelism between their directions.

The most common forms for the paths of the points of a piece of mechanism, whose motion is simple shifting, are the straight line and the circle.

Shifting in a straight line is regulated either by straight fixed guides, in contact with which the moving piece slides, or by combinations of link-work, called *parallel motions*, which will be described in the sequel. Shifting in a straight line is usually *reciprocating;* that is to say, the piece, after shifting through a certain distance, returns to its original position by reversing its motion.

Circular shifting is regulated by attaching two or more points of the shifting piece to ends of equal and parallel rotating cranks, or by combinations of wheel-work to be afterwards described. As an example of circular shifting, may be cited the motion of the coupling rod, by which the parallel and equal cranks upon two or more axles of a locomotive engine are connected and made to rotate simultaneously. The coupling rod remains always parallel to itself, and all its points describe equal and similar circles relatively to the frame of the engine, and move in parallel directions with equal velocities at the same instant.

37. *Turning or Rotation in general.*—Turning or rotation is a motion of a body such that a line fixed in or relatively to the body changes its direction. The *plane of rotation* is a plane parallel to those lines in the body whose change of direction is most rapid. As the rigidity of the body makes all lines in it preserve unchanged their directions relatively to each other, all lines in the body parallel to the plane of rotation change their direction by the same amount in the same interval of time. The *rate* of change of direction of such lines, which, if uniform, is the angle swept through by each of them in an unit of time, and, if variable, is the limit towards which that angle approximates in the operation of differentiation, is the *angular velocity of rotation* of the body, and is denoted by $\frac{d\theta}{dt}$, where θ is the angle made by a line fixed in the body with some fixed direction in the plane of rotation.

Each one of the parts of a rigid turning body, how small soever, turns in the same manner and in the same time with the whole body, and has obviously the same angular velocity of rotation with the whole body.

The *direction of the axis of rotation* is perpendicular to the plane of rotation, and is the direction of all those lines in the body whose rate of change of direction is null. This direction may either be *permanent* or *instantaneous.* It, or any line parallel to it, is sometimes called the *axis* simply; but the use of the word *axis* alone more commonly implies, in speaking of mechanism, a line in the body (such as the central line of an arbor or shaft) whose *position* as well as its direction is unchanged, either relatively to the frame (in which case it is a *fixed* axis), or relatively to some other piece of mechanism which carries the turning piece under consideration. When there is no fixed axis, the *instantaneous axis* is an ideal line, which at a given instant is at rest relatively to the turning body and to the frame.

Rotation is said to be *right-handed* relatively to an observer looking in the direction of the axis, when it is like that of the hands of a watch; *left-handed* when the contrary. Rotation may be *alternately* right and left handed, in which case it is called *oscillation.* Angular velocity of rotation may be *deviated* either by acceleration, by retardation, or by change in the direction of the axis.

38. *Relative Motions of Two Points in a Turning Body.*—Let A and B denote any two points in a turning body, and let it be required to express the motion of B relatively to A. Through A draw a line AO in the direction of the axis, on which let fall a perpendicular from B; let r denote the length of that perpendicular. Then is the motion of B relatively to A a translation in a circular path of the radius r about the axis AO; the *angular velocity of deviation* of B is the same with the angular velocity of rotation of the body $\frac{d\theta}{dt}$, and the linear velocity of B relatively to A is $r\frac{d\theta}{dt}$, in a direction perpendicular to the plane AOB.

The motion of A relatively to B is exactly the same with that of B relatively to A.

39. *Comparative Motion of Two Points relatively to a Third.*—If there be a point C at the perpendicular distance r' from AO, the velocity of that point in its motion relatively to A will be $r'\frac{d\theta}{dt}$; and the *comparative motion* of B and C relatively to A will be expressed by the ratio $r : r'$ between their velocities, and by the angle $\overset{\wedge}{r\,r'}$ between their directions of motion, being the same with the angle between the planes AOB and AOC. Thus that comparative motion is independent of the angular velocity of the turning body.

40. *Rotation about a Fixed Axis—Lever, Wheel, and Axle.*—The fixed axis of a turning body is a line fixed relatively to the body and relatively to the fixed space in which the body turns. In mechanism it is usually the central line either of a rotating shaft or axle having journals, gudgeons, or pivots turning in fixed bearings, or of a fixed spindle or dead centre round which a rotating bush turns; but it may sometimes be entirely beyond the limits of the turning body. For example, if a sliding piece moves in circular fixed guides, that piece rotates about an ideal fixed axis traversing the centre of those guides.

Let the angular velocity of the rotation be denoted by

$\alpha=\frac{d\theta}{dt}$, then the linear velocity of any point A at the distance r from the axis is αr; and the path of that point is a circle of the radius r described about the axis.

If the directions of motion of any two points A and B in the rotating body, at any one instant, be given, the axis may be determined by its being the line of intersection of two planes drawn through A and B, and perpendicular to the respective directions of motion of those points.

The *comparative motion* of A and B is expressed, like that of B and C in sec. 39, by a constant *velocity-ratio*, which is that of their perpendicular distances from the axis, and a constant *directional relation*, which is an angle equal to the angle between the two planes traversing the axis and the two points respectively. This is the principle of the modification of motion by the LEVER, which consists of a rigid body turning about a fixed axis called a fulcrum, and having two points at the same or different distances from that axis, and in the same or different directions, one of which receives motion and the other transmits motion, modified in direction and velocity according to the above law.

In the WHEEL AND AXLE motion is received and transmitted by two cylindrical surfaces of different radii described about their common fixed axis of turning, their velocity-ratio being that of their radii.

41. *Velocity-ratio of Components of Motion.*—As the distance between any two points in a rigid body is invariable, the projections of their velocities upon the line joining them must be equal. Hence it follows, that if A in fig. 5 be a point in a rigid body CD, rotating round the fixed axis F, the component of the velocity of A in any direction AP parallel to the plane of rotation, is equal to the total velocity of the point m, found by letting fall Fm perpendicular to AP; that is to say, is equal to

$$\alpha\cdot\overline{\mathrm{F}m}.$$

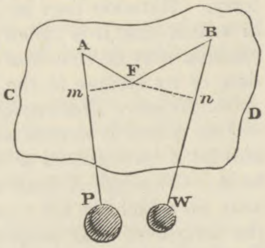

Fig. 5.

Hence also the ratio of the components of the velocities of two points A and B in the directions AP and BW respectively, both in the plane of rotation, is equal to the ratio of the perpendiculars $\overline{\mathrm{F}m}$ and $\overline{\mathrm{F}n}$.

42. *Instantaneous Axis of a Cylinder rolling on a Cylinder.*—Let a cylinder *bbb*, whose axis of figure is B, and angular velocity γ, roll on a fixed cylinder *aaa*, whose axis of figure is A, either outside (as in fig. 6), when the rolling will be towards the same hand with the rotation, or inside (as in fig. 7), when the rolling will be towards the opposite hand; and at a given instant let T be the line of contact of the two cylindrical surfaces, which is at their common intersection with the plane AB traversing the two axes of figure.

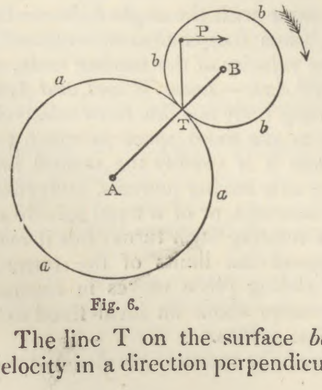

Fig. 6.

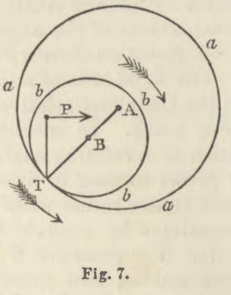

Fig. 7.

The line T on the surface *bbb* has for the instant no velocity in a direction perpendicular to AB; because for the instant it touches, without sliding, the line T on the fixed surface *aaa*.

The line T on the surface *bbb* has also for the instant no velocity in the plane AB; for it has just ceased to move towards the fixed surface *aaa*, and is just about to begin to move away from that surface.

The line of contact T, therefore, on the surface of the cylinder *bbb*, is *for the instant* at rest, and is the *instantaneous axis* about which the cylinder *bbb* turns, together with any body rigidly attached to that cylinder.

To find, then, the direction and velocity at the given instant of any point P, either in or rigidly attached to the rolling cylinder T, draw the plane PT; the direction of motion of P will be perpendicular to that plane, and towards the right or left hand according to the direction of the rotation of *bbb*; and the velocity of P will be

$$v_{\mathrm{P}}=\gamma\cdot\overline{\mathrm{PT}}; \quad .\ .\ .\ .\ .\ (9.)$$

$\overline{\mathrm{PT}}$ denoting the perpendicular distance of P from T. The path of P is a curve of the kind called *epitrochoids*. If P is in the circumference of *bbb*, that path becomes an *epicycloid.*

The velocity of any point in the axis of figure B is

$$v_{\mathrm{B}}=\gamma\cdot\overline{\mathrm{TB}}; \quad .\ .\ .\ .\ (10.)$$

and the path of such a point is a circle described about A with the radius $\overline{\mathrm{AB}}$, being for outside rolling the sum, and for inside rolling the difference, of the radii of the cylinders.

Let α denote the angular velocity with which the *plane of axes* AB rotates about the fixed axis A. Then it is evident that

$$v_{\mathrm{B}}=\alpha\cdot\overline{\mathrm{AB}} \quad .\ .\ .\ .\ .\ (11.)$$

and consequently that $\alpha=\gamma\cdot\frac{\overline{\mathrm{TB}}}{\overline{\mathrm{AB}}}$ . . . . . (12.)

For internal rolling, as in fig. 7, AB is to be treated as negative, which will give a negative value to α, indicating that in this case the rotation of AB round A is contrary to that of the cylinder *bbb*.

The angular velocity of the rolling cylinder, *relatively to the plane of axes* AB, is obviously given by the equation—

$$\left.\begin{array}{r}\beta=\gamma-\alpha;\\ \text{whence } \beta=\gamma\cdot\frac{\overline{\mathrm{TA}}}{\overline{\mathrm{AB}}};\end{array}\right\} \quad .\ .\ .\ .\ (13.)$$

care being taken to attend to the sign of α, so that when that is negative the arithmetical values of γ and α are to be added in order to give that of β.

The whole of the foregoing reasonings are applicable, not merely when *aaa* and *bbb* are actual cylinders, but also when they are the osculating cylinders of a pair of cylindroidal surfaces of varying curvature, A and B being the axes of curvature of the parts of those surfaces which are in contact for the instant under consideration.

43. *Composition and Resolution of Rotations about Parallel Axes.*—The plane AB may be considered as an arm rotating about the fixed axis A with the angular velocity α, and *carrying* the moving axis B, round which a body *bbb* rotates with the angular velocity β *relatively* to the plane or arm AB; so that the actual rotation of *bbb* about the instantaneous axis T, with a total or actual angular velocity γ, is the *resultant* of the two *component rotations* about A and B respectively.

The relations between the angular velocities of the component and resultant rotations, and the distances between their axes, are expressed by the following proportions deduced from equations 12 and 13:—

$$\left.\begin{array}{l} \alpha : \beta : \gamma \\ :: \overline{\mathrm{TB}} : \overline{\mathrm{TA}} : \overline{\mathrm{AB}} \end{array}\right\} \quad . \; . \; . \; . \quad (14.)$$

or in words as follows:—*The angular velocity of the rotation resulting from the composition of two rotations about parallel axes, is the sum of the component angular velocities if they are in the same direction, and their difference if they are contrary: the axis of the resultant rotation lies in the plane of and parallel to the axes of the component rotations—between them if they are in the same direction, beyond them if they are contrary; and its respective distances from these two axes are inversely as the angular velocities of the respective component rotations round them.*

44. *Composition of a Rotation with a Translation in the same Plane.*—The motion of the body *bbb*, and of any body attached to it, may also be regarded as compounded of the rotation, with the total angular velocity γ, about the moving axis B, and a *translation* of that axis, carrying the body along with it, in a direction perpendicular to BA with the velocity v_{B}. Hence is deduced the following rule for finding the motion resulting from the combination of a rotation, with a given total angular velocity γ, about a moving axis B, and a translation in a given direction perpendicular to B with the velocity v_{B}:—

Draw BA perpendicular to the direction of translation, and deviating from that direction to that side towards which the rotation takes place. In BA take

$$\overline{\mathrm{BT}} = \frac{v_{\mathrm{B}}}{\gamma}; \quad . \; . \; . \; . \; . \; . \quad (15.)$$

then the *instantaneous axis* for the instant under consideration is a line drawn through T parallel to B; so that the motion of any point P, in or attached to the body, is for the instant perpendicular to PT, with the velocity

$$v_{\mathrm{P}} = \gamma \cdot \overline{\mathrm{TP}} \quad . \; . \; . \; . \; . \; . \quad (16.)$$

45. *Instantaneous Axis of a Cone rolling on a Cone.*—Let O*aa* (fig. 8) be a fixed cone, OA its axis, O*bb* a cone rolling on it, OB the axis of the rolling cone, OT the line of contact of the two cones at the instant under consideration. By reasoning similar to that of sec. 42, it appears that OT is the instantaneous axis of rotation of the rolling cone.

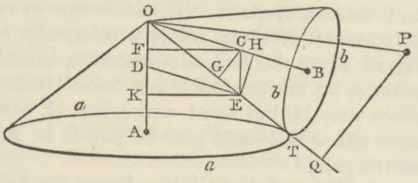

Fig. 8.

Let γ denote the total angular velocity of the rotation of the cone B about the instantaneous axis, β its angular velocity about the axis OB *relatively* to the plane AOB, and α the angular velocity with which the plane AOB turns round the axis OA.

It is required to find the ratios of those angular velocities.

Solution. In OT take any point E, from which draw EC parallel to OA, and ED parallel to OB, so as to construct the parallelogram OCED. Then

$$\left.\begin{array}{l} \overline{\mathrm{OD}} : \overline{\mathrm{OC}} : \overline{\mathrm{OE}} \\ :: \; \alpha \; : \; \beta \; : \; \gamma \end{array}\right\} \quad . \; . \; . \; . \quad (17.)$$

Or because of the proportionality of the sides of triangles to the sines of the opposite angles,

$$\left.\begin{array}{l} \sin \angle \mathrm{TOB} : \sin \angle \mathrm{TOA} : \sin \angle \mathrm{AOB} \\ :: \qquad \alpha \quad : \qquad \beta \quad : \qquad \gamma \end{array}\right\} \; . \quad (17, \mathrm{A.})$$

that is to say, the angular velocity about each axis is proportional to the sine of the angle between the other two.

Demonstration.—From C draw CF ⊥ OA, and CG ⊥ OE.

$$\text{Then } \overline{\mathrm{CF}} = 2 \times \frac{\text{area ECO}}{\mathrm{CE}},$$

$$\text{and } \overline{\mathrm{CG}} = 2 \times \frac{\text{area ECO}}{\mathrm{OE}},$$

$$\therefore \overline{\mathrm{CG}} : \overline{\mathrm{CF}} :: \overline{\mathrm{CE}} = \overline{\mathrm{OD}} : \overline{\mathrm{OE}}.$$

Let v_{C} denote the linear velocity of the point C. Then

$$v_{\mathrm{C}} = \alpha \cdot \overline{\mathrm{CF}} = \gamma \cdot \overline{\mathrm{CG}}$$

$$\therefore \gamma : \alpha :: \overline{\mathrm{CF}} : \overline{\mathrm{CG}} :: \overline{\mathrm{OE}} : \mathrm{OD};$$

which is one part of the solution above stated. From E draw EH ⊥ OB, and EK ⊥ OA. Then it can be shown as before that

$$\overline{\mathrm{EK}} : \overline{\mathrm{EH}} :: \overline{\mathrm{OC}} : \overline{\mathrm{OD}}.$$

Let v_{E} be the linear velocity of the point E *fixed in the plane of axes* AOB. Then

$$v_{\mathrm{E}} = \alpha \cdot \overline{\mathrm{EK}}.$$

Now as the line of contact OT is for the instant at rest on the rolling cone as well as on the fixed cone, the linear velocity of the point E fixed to the plane AOB relatively to the rolling cone, is the same with its velocity relatively to the fixed cone. That is to say,

$$\beta \cdot \overline{\mathrm{EH}} = v_{\mathrm{E}} = \alpha \cdot \overline{\mathrm{EK}}$$

$$\therefore \alpha : \beta :: \overline{\mathrm{EH}} : \overline{\mathrm{EK}} :: \overline{\mathrm{OD}} : \overline{\mathrm{OC}},$$

which is the remainder of the solution. Q.E.D.

The path of a point P in or attached to the rolling cone is a spherical epitrochoid traced on the surface of a sphere of the radius $\overline{\mathrm{OP}}$. From P draw PQ perpendicular to the instantaneous axis. Then the motion of P is perpendicular to the plane OPQ, and its velocity is

$$v_{\mathrm{P}} = \gamma \cdot \overline{\mathrm{PQ}} \quad . \; . \; . \; . \; . \; . \quad (18.)$$

The whole of the foregoing reasonings are applicable, not merely when A and B are actual regular cones, but also when they are the osculating regular cones of a pair of irregular conical surfaces, having a common apex at O.

46. *Composition of Rotations about Two Axes meeting in a Point.*—The plane AOB, carrying the moving axis OB, rotates about the fixed axis OA with an angular velocity α, to which $\overline{\mathrm{OD}}$ is proportioned; the cone B, or any other body, rotates about the moving axis OB with an angular velocity β, to which $\overline{\mathrm{OC}}$ is proportional; then the resultant angular velocity γ of the body B is proportional to, and the direction of the resultant rotation coincides with, the diagonal $\overline{\mathrm{OE}}$ of the parallelogram OCED.

In drawing lines, such as OC, OD, and OE, to represent in direction the axes, and in magnitude the angular velocities, of rotations, care is to be taken to make each line point from the origin O in such a direction that each rotation, looked at *from* the quarter towards which the line denoting it points, shall be of the same kind with all the rest, viz., right-handed or left-handed. Right-handed rotation is usually selected in applying this rule.

47. *Screw-like or Helical Motion.*—As it has been shown in section 44 that the combination of a rotation round a given axis, with a translation of that axis in a path parallel to the plane of rotation, is equivalent simply to a rotation round a different axis, it follows that every possible movement of a rigid body parallel to one plane is either a translation or a rotation; and that the only combination of translation and rotation, in which a complex movement which is not a mere rotation is produced, occurs when the translation is *perpendicular to the plane and parallel to the axis* of rotation.

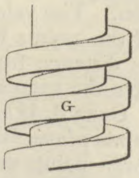

Fig. 9.

Such a complex motion is called *screw-like* or *helical* motion; for each point in the body describes a *helix* or *screw* round the axis of rotation, fixed or instantaneous as the case may be. To cause a body to move in this manner it is usually made of a helical or screw-like figure, and moves in a guide of a corresponding figure. Helical motion and screws adapted to it are said to be right or left-handed according to the appearance presented by the rotation to an observer looking towards the direction of the translation. Thus the screw G in fig. 9 is right-handed.

The translation of a body in helical motion is called its *advance*. Let v_x denote the velocity of advance at a given instant, which of course is common to all the particles of the body; a the angular velocity of the rotation at the same instant; $2\pi=6{\cdot}2832$ nearly, the circumference of a circle of the radius unity. Then

$$T=\frac{2\pi}{a} \quad . \; . \; . \; . \; . \; . \; . \quad (19.)$$

is the time of one turn at the rate a; and

$$p=v_x T=\frac{2\pi v_x}{a} \quad . \; . \; . \; . \quad (20.)$$

is the *pitch* or *advance per turn*; a length which expresses the *comparative motion* of the translation and the rotation.

The pitch of a screw is the distance, measured parallel to its axis, between two successive turns of the same *thread* or helical projection.

Let r denote the perpendicular distance of a point in a body moving helically from the axis. Then

$$v_r=ar, \quad . \; . \; . \; . \; . \; . \; . \quad (21.)$$

is the component of the velocity of that point in a plane perpendicular to the axis, and its total velocity is

$$v=\surd\{v_x^2+v_r^2\} \quad . \; . \; . \; . \quad (22.)$$

The ratio of the two components of that velocity is

$$\frac{v_x}{v_x}=\frac{p}{2\pi r}=\tan\theta; \quad . \; . \; . \; . \quad (23.)$$

where θ denotes the angle made by the helical path of the point with a plane perpendicular to the axis.

48. *To find the Motion of a Rigid Body from the Motions of Three Points in it.*—When the directions and velocities of the motions of any three points in a rigid body, not being in the same straight line, are given, the motion of the whole body is determined, and may be found.

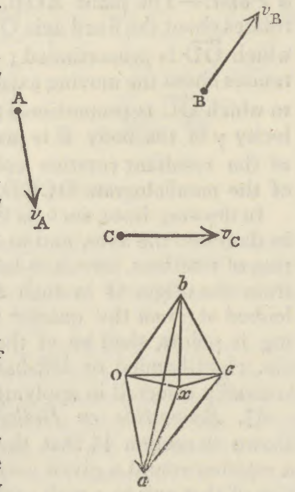

Fig. 10.

CASE 1. *When the velocities of the three points are equal and parallel*, the motion of the whole body is an equal and parallel translation.

CASE 2. *When the three points are in one plane, and their velocities are perpendicular to that plane and unequal.*—Draw three lines from the three points representing in length and direction their velocities. Through the extremities of those lines, draw a plane which will intersect the plane of the three points in the axis of rotation. The velocity of any one of the points being divided by its distance from that axis will give the angular velocity.

CASE 3. *When the motions of the three points are parallel to one plane, but not to each other.*—Through any two of the three points draw planes perpendicular to their directions of motion; those planes will cut each other in the axis of rotation; and the angular velocity may be found as in Case 2.

CASE 4. *In every other case* the motion is helical.—Let A, B, C (fig. 10) be the three points, and let the lines v_A, v_B, v_C, represent their velocities. Through any point O draw

$$Oa = \text{and} \parallel \text{to } v_A,\; Ob = \text{and} \parallel v_B,\; Oc = \text{and} \parallel v_C.$$

Through a, b, and c, draw a plane, on which let fall the perpendicular Ox. This will represent the velocity of *translation or advance*. Join xa, xb, xc; these lines will represent in direction and magnitude the components of the velocities of A, B, C, respectively, parallel to the plane of rotation. Through any two of the three points draw planes perpendicular respectively to these rotatory components of their velocities; those planes will intersect in the axis of rotation. Find the angular velocity as before.

DIVISION IV.—ELEMENTARY COMBINATIONS IN MECHANISM.

49. *Definitions.*—An *elementary combination* in mechanism consists of two pieces whose kinds of motion are determined by their connection with the frame, and their comparative motion by their connection with each other; that connection being effected either by direct contact of the pieces, or by a connecting piece, which is not connected with the frame, and whose motion depends entirely on the motions of the pieces which it connects.

The piece whose motion is the cause is called the *driver*; the piece whose motion is the effect, the *follower*.

The connection of each of those two pieces with the frame is in general such as to determine the path of every point in it. In the investigation, therefore, of the comparative motion of the driver and follower, in an elementary combination, it is unnecessary to consider relations of angular direction, which are already fixed by the connection of each piece with the frame; so that the inquiry is confined to the determination of the velocity-ratio, and of the directional-relation, so far only as it expresses the connection between *forward* and *backward* movements of the driver and follower. When a continuous motion of the driver produces a continuous motion of the follower, forward or backward, and a reciprocating motion a motion reciprocating at the same instant, the directional-relation is said to be *constant*. When a continuous motion produces a reciprocating motion, or *vice versa*; or when a reciprocating motion produces a motion not reciprocating at the same instant, the directional-relation is said to be *variable*.

The *line of action* or *of connection* of the driver and follower is a line traversing a pair of points in the driver and follower respectively, which are so connected that the component of their velocity relatively to each other, resolved along the line of connection, is null. There may be several, or an indefinite number of lines of connection, or there may be but one; and a line of connection may connect either the same pair of points or a succession of different pairs.

50. *General Principle.*—From the definition of a line of connection it follows, that *the components of the velocities of a pair of connected points along their line of connection are equal.* And from this, and from the property of a rigid body, already stated in sect. 41, it follows, that *the components, along a line of connection, of all the points traversed by that line, whether in the driver or in the follower, are equal;* and consequently, *that the velocities of any pair of points, traversed by a line of connection, are to each other inversely as the cosines, or directly as the secants, of the angles made by the paths of those points with the line of connection.*

The general principle, stated above in different forms, serves to solve every problem in which—the mode of connection of a pair of pieces being given—it is required to find their comparative motion at a given instant, or *vice versa.*

51. *Application to a Pair of Shifting Pieces.*—In fig. 11, let P_1P_2 be the line of connection of a pair of pieces, each of which has a motion of translation or shifting. Through any point T in that line draw TV_1, TV_2, respectively parallel to the simultaneous direction of motion of the pieces; through any other point A in the line of connection draw a plane perpendicular to that line, cutting TV_1, TV_2, in V_1, V_2; then,

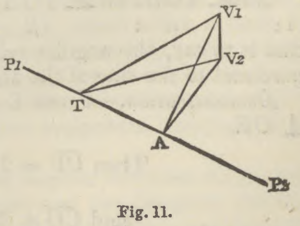

Fig. 11.

velocity of piece 1 : velocity of piece 2 : : $\overline{\mathrm{TV}_1} : \overline{\mathrm{TV}_2}$. Also, TA represents the equal components of the velocities of the pieces parallel to their line of connection, and the line $\overline{\mathrm{V}_1\mathrm{V}_2}$ represents their velocity relatively to each other.

52. *Application to a Pair of Turning Pieces.*—Let α_1, α_2 be the angular velocities of a pair of turning pieces; θ_1, θ_2, the angles which their line of connection makes with their respective planes of rotation; r_1, r_2, the common perpendiculars let fall from the line of connection upon the respective axes of rotation of the pieces. Then the equal components, along the line of connection, of the velocities of the points where those perpendiculars meet that line, are,—

$$\alpha_1 r_1 \cdot \cos\theta_1 = \alpha_2 r_2 \cdot \cos\theta_2;$$

consequently, the comparative motion of the pieces is given by the equation

$$\frac{\alpha_2}{\alpha_1} = \frac{r_1 \cdot \cos\theta_1}{r_2 \cdot \cos\theta_2}. \quad . \quad . \quad . \quad . \quad (24.)$$

53. *Application to a Shifting Piece and a Turning Piece.*—Let a shifting piece be connected with a turning piece, and at a given instant let α_1 be the angular velocity of the turning piece, r_1 the common perpendicular of its axis of rotation and the line of connection, θ_1 the angle made by the line of connection with the plane of rotation, θ_2 the angle made by the line of connection with the direction of motion of the shifting piece, v_2 the linear velocity of that piece. Then

$$\alpha_1 r_1 \cdot \cos\theta_1 = v_2 \cdot \cos\theta_2; \quad . \quad . \quad (25.)$$

which equation expresses the comparative motion of the two pieces.

54. *Classification of Elementary Combinations in Mechanism.*—The first systematic classification of elementary combinations in mechanism was that founded by Monge, and fully developed by Lanz and Bétancourt, which has been generally received, and has been adopted in most treatises on applied mechanics. But that classification is founded on the absolute, instead of the comparative motions of the pieces, and is, for that reason, defective, as Mr Willis has pointed out in his admirable treatise *On the Principles of Mechanism.*

The classification of Mr Willis is founded, in the first place, on comparative motion, as expressed by velocity-ratio and directional-relation; and, in the second place, on the mode of connection of the driver and follower. He divides the elementary combinations in mechanism into three classes, of which the characters are as follows:—

Class A: Directional-relation constant; velocity-ratio constant.

Class B: Directional-relation constant; velocity-ratio varying.

Class C: Directional-relation changing periodically; velocity-ratio constant or varying.

Each of those classes is subdivided by Mr Willis into five divisions, of which the characters are as follows:—

Division A: connection by rolling contact.
... B: ... sliding contact.
... C: ... wrapping connectors.
... D: ... link-work.
... E: ... reduplication.

In the present article the principle of the classification of Mr Willis is followed; but the arrangement is modified by taking the *mode of connection* as the basis of the primary classification, and by removing the subject of connection by reduplication to the section of aggregate combinations. This modified arrangement is adopted as being better suited than the original arrangement to the limits of an article in an Encyclopædia; but it is not disputed that the original arrangement may be the best for a separate treatise.

55. *Rolling Contact—Smooth Wheels and Racks.*—In order that two pieces may move in *rolling contact,* it is necessary that each pair of points in the two pieces which touch each other should at the instant of contact be moving in the same direction with the same velocity. In the case of two *shifting* pieces this would involve equal and parallel velocities for all the points of each piece, so that there could be no rolling, and, in fact, the two pieces would move like one; hence, in the case of rolling contact, either one or both of the pieces must rotate.

The direction of motion of a point in a turning piece being perpendicular to a plane passing through its axis, the condition, that each pair of points in contact with each other must move in the same direction, leads to the following consequences:—

I. That when both pieces rotate, their axes, and all their points of contact, lie in the same plane.

II. That when one piece rotates and the other shifts, the axis of the rotating piece, and all the points of contact, lie in a plane perpendicular to the direction of motion of the shifting piece.

The condition, that the velocities of each pair of points of contact must be equal, leads to the following consequences:—

III. That the angular velocities of a pair of turning pieces in rolling contact must be inversely as the perpendicular distances of any pair of points of contact from the respective axes.

IV. That the linear velocity of a shifting piece in rolling contact with a turning piece is equal to the product of the angular velocity of the turning piece, by the perpendicular distance from its axis to a pair of points of contact.

The *line of contact* is that line in which the points of contact are all situated. Respecting this line, the above principles III. and IV. lead to the following conclusions:—

V. That for a pair of turning pieces with parallel axes, and for a turning piece and a shifting piece, the line of contact is straight, and parallel to the axes or axis; and hence that the rolling surfaces are either plane or cylindrical (the term "cylindrical" including all surfaces generated by the motion of a straight line parallel to itself).

VI. That for a pair of turning pieces, with intersecting axes, the line of contact is also straight, and traverses the point of intersection of the axes; and hence that the rolling surfaces are conical, with a common apex (the term "conical" including all surfaces generated by the motion of a straight line which traverses a fixed point).

Turning pieces in rolling contact are called *smooth,* or *toothless wheels.* Shifting pieces in rolling contact with turning pieces may be called *smooth* or *toothless racks.*

VII. In a pair of pieces in rolling contact every straight line traversing the line of contact is a line of connection.

56. *Cylindrical Wheels and Smooth Racks.*—In designing cylindrical wheels and smooth racks, and determining their comparative motion, it is sufficient to consider a section of the pair of pieces made by a plane perpendicular to the axis or axes.

The points where axes intersect the plane of section are called *centres;* the point where the line of contact intersects it, the *point of contact,* or *pitch-point;* and the wheels are described as *circular, elliptical,* &c., according to the forms of their sections made by that plane.

When the point of contact of two wheels lies between their centres, they are said to be in *outside gearing;* when beyond their centres, in *inside gearing;* because the rolling surface of the larger wheel must in this case be turned inwards, or towards its centre.

From principle III. of sect. 55 it appears, that the angular velocity-ratio of a pair of wheels is the inverse ratio of the distances of the point of contact from the centres respectively.

For outside gearing that ratio is *negative,* because the wheels turn contrary ways; for inside gearing it is *positive*, because they turn the same way.

If the velocity-ratio is to be constant, as in Mr Willis's Class A, the wheels must be circular; and this is the most common form for wheels.

If the velocity-ratio is to be variable, as in Mr Willis's Class B, the figures of the wheels are a pair of *rolling curves*, subject to the condition that the distance between their *poles* (which are the centres of rotation) shall be constant.

The following is the geometrical relation which must exist between such a pair of curves. (See fig. 12.)

Let C_1, C_2 be the poles of a pair of rolling curves; T_1, T_2 any pair of points of contact; U_1, U_2 any other pair of points of contact. Then, for every possible pair of points of contact, the two following equations must be simultaneously fulfilled:—

$$\text{Sum of radii, } \overline{C_1U_1}+\overline{C_2U_2}=\overline{C_1T_1}+\overline{C_2T_2}=\text{constant};$$
$$\text{arc, } \overline{T_2U_2}=\overline{T_1U_1} \quad . \quad . \quad . \qquad (26.)$$

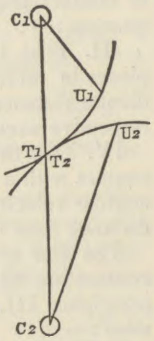

Fig. 12.

A condition equivalent to the above, and necessarily connected with it, is, that at each pair of points of contact the inclinations of the curves to their radii-vectores shall be equal and contrary; or, denoting by r_1, r_2 the radii-vectores at any given pair of points of contact, and s the length of the equal arcs measured from a certain fixed pair of points of contact—

$$\frac{dr_2}{ds}=-\frac{dr_1}{ds}; \quad . \quad . \qquad (27.)$$

which is the differential equation of a pair of rolling curves whose poles are at a constant distance apart.

[For full details as to rolling curves, see Mr Willis's work, already mentioned, and Mr Clerk Maxwell's paper on Rolling Curves in the *Transactions of the Royal Society of Edinburgh.*]

A rack, to work with a circular wheel, must be straight. To work with a wheel of any other figure, its section must be a rolling curve, subject to the condition, that the perpendicular distance from the pole or centre of the wheel to a straight line parallel to the direction of the motion of the rack shall be constant. Let r_1 be the radius-vector of a point of contact on the wheel, x_2 the ordinate from the straight line before mentioned to the corresponding point of contact on the rack. Then

$$\frac{dx_2}{ds}=\frac{dr_1}{ds} \quad . \quad . \quad . \quad . \qquad (28.)$$

is the differential equation of the pair of rolling curves.

To illustrate this subject, it may be mentioned that an ellipse rotating about one focus rolls completely round in outside gearing, with an equal and similar ellipse also rotating about one focus, the distance between the axes of rotation being equal to the major axis of the ellipses, and the velocity-ratio varying from $\frac{1+\text{eccentricity}}{1-\text{eccentricity}}$ to $\frac{1-\text{eccentricity}}{1+\text{eccentricity}}$; a hyperbola rotating about its further focus rolls, in inside gearing, through a limited arc, with an equal and similar hyperbola rotating about its nearer focus, the distance between the axes of rotation being equal to the axis of the hyperbolas, and the velocity-ratio varying between $\frac{\text{eccentricity}+1}{\text{eccentricity}-1}$ and unity; and a parabola rotating about its focus rolls with an equal and similar parabola, shifting parallel to its directrix.

57. *Conical or Bevel, and Disc Wheels.*—From principles III. and VI. of sect. 55 it appears, that the angular velocities of a pair of wheels whose axes meet in a point, are to each other inversely as the sines of the angles which the axes of the wheels make with the line of contact. Hence follows the following construction (figs. 13 and 14).—Let O be the apex or point of meeting of the two axes OC_1, OC_2. The angular-velocity-ratio being given, it is required to find the line *of contact.* On OC_1, OC_2 take lengths $\overline{OA_1}$, $\overline{OA_2}$, respectively proportional to the angular velocities of the pieces on whose axes they are taken. Complete the parallelogram OA_1EA_2; the diagonal OET will be the line of contact required.

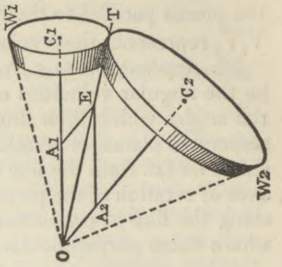

Fig. 13.

When the velocity-ratio is variable, the line of contact will shift its position in the plane C_1OC_2, and the wheels will be cones, with eccentric or irregular bases. In every case which occurs in practice, however, the velocity-ratio is constant; the line of contact is constant in position, and the rolling surfaces of the wheels are regular circular cones (when they are called *bevel wheels*); or one of a pair of wheels may have a flat disc for its rolling surface, as W_2 in fig. 14, in which case it is a *disc wheel.* The rolling surfaces of actual wheels consist of frusta or zones of the complete cones or discs, as shown by W_1, W_2, in figs. 13 and 14.

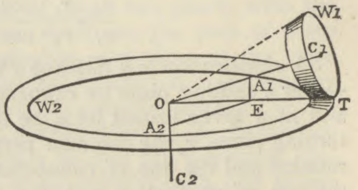

Fig. 14.

58. *Sliding Contact—lateral: Skew-Bevel Wheels.*—A hyperboloid of revolution is a surface resembling a sheaf or a dice box, generated by the rotation of a straight line round an axis from which it is at a constant distance, and to which it is inclined at a constant angle. If two such hyperboloids, equal or unequal, be placed in the closest possible contact, as in fig. 15, they will touch each other along one of the generating straight lines of each, which will form their line of contact, and will be inclined to the axes AG, BH in opposite directions. The axes will neither be parallel nor will they intersect each other.

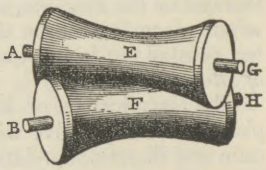

Fig. 15.

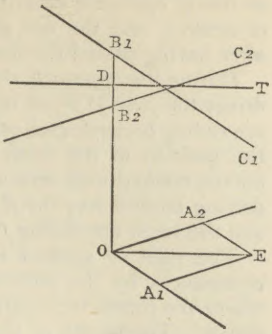
The motion of two such hyperboloids, turning in contact with each other, has hitherto been classed amongst cases of rolling contact; but that classification is not strictly correct: for although the component velocities of a pair of points of contact in a direction at right angles to the line of contact are equal, still, as the axes are neither parallel to each other nor to the line of contact, the velocities of a pair of points of contact have components along the line of contact which are unequal, and their difference constitutes a *lateral sliding.*

The directions and positions of the axes being given, and the required angular-velocity-ratio, the following construction serves to determine the line of contact, by whose rotation round the two axes respectively the hyperboloids are generated:—

In fig. 16, let B_1C_1, B_2C_2 be the two axes; B_1B_2 their common perpendicular. Through any point O in this common perpendicular draw OA_1 parallel to B_1C_1, OA_2 parallel to B_2C_2; make those lines proportional to the angular velocities about the axes to which they are respectively parallel; complete the parallelogram OA_1EA_2, and draw the diagonal OE; divide B_1B_2 in D into two parts, *inversely* proportional to the angular velocities about the axes which they respectively adjoin; through D parallel to OE draw DT. This will be the line of contact.



Fig, 16.

A pair of thin frusta of a pair of hyperboloids are used in practice to communicate motion between a pair of axes neither parallel nor intersecting, and are called *skew-bevel wheels.*

In skew-bevel wheels, the properties of a line of connection are not possessed by every line traversing the line of contact, but only by every line traversing the line of contact at right angles.

If the velocity-ratio to be communicated were variable, the point D would alter its position, and the line DT its direction, at different periods of the motion, and the wheels would be hyperboloids of an eccentric or irregular cross section; but forms of this kind are not used in practice.

59. *Sliding Contact—circular: Grooved Wheels.*—As the adhesion or friction between a pair of smooth wheels is seldom sufficient to prevent their slipping on each other, contrivances are used to increase their mutual hold. One of those consists in forming the rim of each wheel into a series of alternate ridges and grooves parallel to the plane of rotation; it is applicable to cylindrical and bevel wheels, but not to skew-bevel wheels. The comparative motion of a pair of wheels so ridged and grooved is the same with that of a pair of smooth wheels in rolling contact, whose cylindrical or conical surfaces lie midway between the tops of the ridges and bottoms of the grooves, and those ideal smooth surfaces are called the *pitch surfaces* of the wheels.

The relative motion of the faces of contact of the ridges and grooves is a *rotatory sliding*, or *grinding* motion, about the line of contact of the pitch-surfaces as an instantaneous axis.

Grooved wheels have hitherto been but little used.

60. *Sliding Contact—direct: Teeth of Wheels, Number and Pitch.*—The ordinary method of connecting a pair of wheels, or a wheel and a rack, and the only method which insures the exact maintenance of a given numerical velocity-ratio, is by means of a series of alternate ridges and hollows parallel or nearly parallel, to the successive lines of contact of the ideal smooth wheels, whose velocity-ratio would be the same with that of the toothed wheels. The ridges are called *teeth;* the hollows, *spaces.* The teeth of the driver push those of the follower before them, and in so doing sliding takes place between them in a direction across their lines of contact.

The *pitch-surfaces* of a pair of toothed wheels are the ideal smooth surfaces, which would have the same comparative motion by rolling contact which the actual wheels have by the sliding contact of their teeth. The *pitch-circles* of a pair of circular toothed wheels are sections of their pitch-surfaces, made for *spur-wheels* (that is, for wheels whose axes are parallel) by a plane at right angles to the axes, and for bevel wheels by a sphere described about the common apex. For a pair of skew-bevel wheels the pitch-circles are a pair of contiguous rectangular sections of the pitch-surfaces. The *pitch-point* is the point of contact of the pitch-circle.

The pitch-surface of a wheel lies intermediate between the points of the teeth and the bottoms of the hollows between them. That part of the acting surface of a tooth which projects beyond the pitch-surface is called the *face;* that part which lies within the pitch-surface, the *flank.*

Teeth, when not otherwise specified, are understood to be made in one piece with the wheel; the material being generally cast-iron, brass, or bronze. Separate teeth, fixed into mortises in the rim of the wheel, are called *cogs.* A *pinion* is a small toothed wheel; a *trundle* is a pinion with cylindrical *staves* for teeth.

The radius of the pitch-circle of a wheel is called the *geometrical radius;* a circle touching the ends of the teeth is called the *addendum circle,* and its radius the *real radius;* the difference between these radii, being the projection of the teeth beyond the pitch-surface, is called the *addendum.*

The distance, measured along the pitch-circle, from the face of one tooth to the face of the next, is called the *pitch.* The pitch and the number of teeth in wheels are regulated by the following principles:—

I. In wheels which rotate continuously for one revolution or more, it is obviously necessary *that the pitch should be an aliquot part of the circumference.*

In wheels which reciprocate without performing a complete revolution this condition is not necessary. Such wheels are called *sectors.*

II. In order that a pair of wheels, or a wheel and a rack, may work correctly together, it is in all cases essential *that the pitch should be the same in each.*

III. Hence, in any pair of circular wheels which work together, the numbers of teeth in a complete circumference are directly as the radii, and inversely as the angular-velocities.

IV. Hence also in any pair of circular wheels which rotate continuously for one revolution or more, the ratio of the numbers of teeth and its reciprocal, the angular-velocity-ratio, must be expressible in whole numbers.

From this principle arise problems of a kind which will be referred to in treating of *Trains of Mechanism.*

V. Let n, N be the respective numbers of teeth in a pair of wheels, N being the greater. Let t, T be a pair of teeth in the smaller and larger wheel respectively, which at a particular instant work together. It is required to find, first, how many pairs of teeth must pass the line of contact of the pitch-surfaces before t and T work together again (let this number be called a); and, secondly, with how many different teeth of the larger wheel the tooth t will work at different times (let this number be called b); thirdly, with how many different teeth of the smaller wheel the tooth T will work at different times (let this be called c).

CASE 1. If n is a divisor of N,

$$a = \mathrm{N}; \; b = \frac{\mathrm{N}}{n}; \; c = 1. \quad . \quad . \quad . \quad (29.)$$

CASE 2. If the greatest common divisor of N and n be d, a number less than n, so that $n = md$; $\mathrm{N} = \mathrm{M}d$; then

$$a = m\mathrm{N} = \mathrm{M}n = \mathrm{M}md; \; b = \mathrm{M}; \; c = m. \quad . \quad (30.)$$

CASE 3. If N and n be prime to each other,

$$a = \mathrm{N}n; \; b = \mathrm{N}; \; c = n. \quad . \quad . \quad . \quad (31.)$$

It is considered desirable by millwrights, with a view to the preservation of the uniformity of shape of the teeth of a pair of wheels, that each given tooth in one wheel should work with as many different teeth in the other wheel as possible. They therefore study that the numbers of teeth in each pair of wheels which work together shall either be prime to each other, or shall have their greatest common divisor as small as is consistent with a velocity-ratio suited for the purposes of the machine.

61. *Sliding Contact—Forms of the Teeth of Spur-wheels and Racks.*—A line of connection of two pieces in sliding contact is a line perpendicular to their surfaces at a point where they touch. Bearing this in mind, the principle of the comparative motion of a pair of teeth belonging to a pair of spur-wheels, or to a spur-wheel and a rack, is found by applying the principles stated generally in §§ 52 and 53 to the case of parallel axes for a pair of spur-wheels, and to the case of an axis perpendicular to the direction of shifting for a wheel and a rack.

In fig. 17, let C_1, C_2 be the centres of a pair of spur-wheels; $B_1IB'_1$, $B_2IB'_2$, portions of their pitch-circles, touching at I, the pitch-point. Let the wheel 1 be the driver, and the wheel 2 the follower.

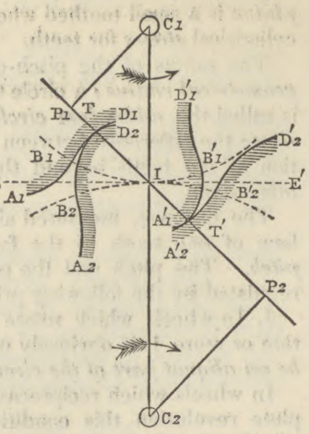


Fig 17.

Let $D_1TB_1A_1$, $D_2TB_2A_2$ be the positions, at a given instant, of the acting surfaces of a pair of teeth in the driver and follower respectively, touching each other at T; the line of connection of those teeth is P_1P_2, perpendicular to their surfaces at T. Let C_1P_1, C_2P_2, be perpendiculars let fall from the centres of the wheels on the line of contact. Then, by sect. 52, the angular-velocity-ratio is

$$\frac{\alpha_2}{\alpha_1} = \frac{\overline{C_1P_1}}{\overline{C_2P_2}} \quad . \quad . \quad . \quad . \quad (32.)$$

The following principles regulate the forms of the teeth and their relative motions:—

I. The angular-velocity-ratio due to the sliding contact of the teeth will be the same with that due to the rolling contact of the pitch-circles, if the line of connection of the teeth cuts the line of centres at the pitch-point.

For, let P_1P_2 cut the line of centres at I; then, by similar triangles,

$$\alpha_1 : \alpha_2 : : \overline{C_2P_2} : \overline{C_1P_1} : : \overline{IC_2} : : \overline{IC_1} ; \quad . \quad (33.)$$

which is also the angular-velocity-ratio due to the rolling contact of the circles $B_1IB'_1$, $B_2IB'_2$.

This principle determines the *forms* of all teeth of spur-wheels. It also determines the forms of the teeth of straight racks, if one of the centres be removed, and a straight line EIE', parallel to the direction of motion of the rack, and perpendicular to C_1IC_2, be substituted for a pitch-circle.

II. The component of the velocity of the point of contact of the teeth T along the line of connection is,

$$\alpha_1 \cdot \overline{C_1P_1} = \alpha_2 \cdot \overline{C_2P_2}. \quad . \quad . \quad . \quad (34.)$$

III. The relative velocity perpendicular to P_1P_2 of the teeth at their point of contact,—that is, their *velocity of sliding* on each other,—is found by supposing one of the wheels, such as 1, to be fixed; the line of centres C_1C_2 to rotate backwards round C_1 with the angular velocity α_1, and the wheel 2 to rotate round C_2 as before, with the angular velocity α_2 relatively to the line of centres C_1C_2, so as to have the same motion as if its pitch-circle *rolled* on the pitch-circle of the first wheel. Thus the *relative* motion of the wheels is unchanged; but 1 is considered as fixed, and 2 has the *total motion* given by the principles of sects. 42 and 43; that is, a rotation about the instantaneous axis I, with the angular velocity $\alpha_1 + \alpha_2$. Hence the *velocity of sliding* is that due to this rotation about I, with the radius IT; that is to say, its value is

$$(\alpha_1 + \alpha_2) \cdot \overline{IT} ; \quad . \quad . \quad . \quad . \quad (35.)$$

so that it is greater the further the point of contact is from the line of centres; and at the instant when that point passes the line of centres, and coincides with the *pitch-point*, the velocity of sliding is null, and the action of the teeth is, for the instant, that of rolling contact.

IV. The *path of contact* is the line traversing the various positions of the point T. If the line of connection preserves always the same position, the path of contact coincides with it, and is straight; in other cases the path of contact is curved.

It is divided by the pitch-point I into two parts: the *arc or line of approach* described by T in approaching the line of centres, and the *arc* or *line of recess* described by T after having passed the line of centres.

During the *approach*, the *flank* D_1B_1 of the driving tooth drives the *face* D_2B_2 of the following tooth, and the teeth are sliding *towards* each other. During the *recess* (in which the position of the teeth is exemplified in the figure by curves marked with accented letters), the *face* $B'_1A'_1$ of the driving tooth drives the *flank* $B'_2A'_2$ of the following tooth, and the teeth are sliding *from* each other.

The path of contact is bounded where the approach commences by the addendum-circle of the follower, and where the recess terminates by the addendum-circle of the driver. The length of the path of contact should be such that there shall always be at least one pair of teeth in contact; and it is better still to make it so long that there shall always be at least two pairs of teeth in contact.

V. The *obliquity* of the action of the teeth is the angle $EIT = IC_1P_1 = IC_2P_2$.

In practice it is found desirable that the mean value of the obliquity of action during the contact of teeth should not exceed 15°, nor the maximum value 30°.

It is unnecessary to give separate figures and demonstrations for inside gearing. The only modification required in the formulæ is, that in equation 3 the *difference* of the angular velocities should be substituted for their sum.

62. *Involute Teeth.*—The simplest form of tooth which fulfils the conditions of sect. 61 is obtained in the following manner (see fig. 18). Let C_1, C_2 be the centres of two wheels, $B_1IB'_1$, $B_2IB'_2$ their pitch-circles, I the pitch-point; let the obliquity of action of the teeth be constant, so that the same straight line P_1IP_2 shall represent at once the constant line of connection of teeth and the path of contact. Draw C_1P_1, C_2P_2 perpendicular to P_1IP_2, and with those lines as radii describe about the centres of the wheels the circles D'_1, $D_2D'_2$, called *base-circles*. It is evident that the radii of the base-circles bear to each other the same proportions as the radii of the pitch-circles; and also that

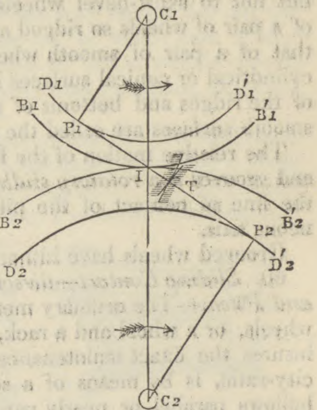

Fig. 18.

$$\left.\begin{array}{l} \overline{C_1P_1} = \overline{IC_1} \cdot \cos \cdot \text{obliquity} \\ \overline{C_2P_2} = \overline{IC_2} \cdot \cos \cdot \text{obliquity} \end{array}\right\} \quad . \quad . \quad . \quad (36.)$$

(The obliquity which is found to answer best in practice is about 14½°; its cosine is about $\frac{31}{32}$, and its sine about $\frac{1}{4}$. These values, though not absolutely exact, are near enough to the truth for practical purposes.)

Suppose the base-circles to be a pair of circular pulleys connected by means of a cord whose course from pulley to pulley is P_1IP_2. As the line of connection of those pulleys is the same with that of the proposed teeth, they will rotate with the required velocity-ratio. Now, suppose a tracing point T to be fixed to the cord, so as to be carried along the path of contact P_1IP_2, that point will trace, on a plane rotating along with the wheel 1, part of the involute of the base-circle $D_1D'_1$; and on a plane rotating along with the wheel 2, part of the involute of the base-circle $D_2D'_2$; and the two curves so traced will always touch each other in the required point of contact T, and will therefore fulfil the condition required by principle I. of sect. 61.

Consequently, one of the forms suitable for the teeth of wheels is the involute of a circle; and the obliquity of the action of such teeth is the angle whose cosine is the ratio of the radius of their base-circle to that of the pitch-circle of the wheel.

All involute teeth of the same pitch work smoothly together.

To find the length of the path of contact on either side of the pitch-point I, it is to be observed that the distance between the fronts of two successive teeth, as measured along P_1IP_2, is less than the pitch in the ratio of cos · obliquity : 1; and, consequently, that if distances equal to the pitch be marked off either way from I towards P_1 and P_2 respectively, as the extremities of the path of contact; and if, according to principle IV. of sect. 61, the addendum-circles be described through the points so found, there will always be at least two pairs of teeth in action at once. In practice it is usual to make the path of contact somewhat longer, viz., about $2\frac{4}{10}$th times the pitch; and with this length of path, and the obliquity already mentioned of $14\frac{1}{2}°$, the addendum is about $\frac{3}{10}$ths of the pitch.

The teeth of a *rack*, to work correctly with wheels having involute teeth, should have plane surfaces perpendicular to the line of connection, and consequently making, with the direction of motion of the rack, angles equal to the complement of the obliquity of action.

63. *Teeth for a given Path of Contact—Mr Sang's method.*—In the preceding section the form of the teeth is found by assuming a figure for the path of contact, viz., the straight line. Any other convenient figure may be assumed for the path of contact, and the corresponding forms of the teeth found, by determining what curves a point T, moving along the assumed path of contact, will trace on two discs rotating round the centres of the wheels with angular velocities bearing that relation to the component velocity of T along TI, which is given by principle II. of sect. 61, and by equation 34. This method of finding the forms of the teeth of wheels forms the subject of an elaborate and most interesting treatise by Mr Edward Sang.

All wheels having teeth of the same pitch, traced from the same path of contact, work correctly together, and are said to belong to the *same set*.

64. *Teeth traced by Rolling Curves.*—If any curve R be rolled on the inside of the pitch-circle BB of a wheel, it appears, from sect. 42, that the instantaneous axis of the rolling curve at any instant will be at the point I, where it touches the pitch-circle for the moment, and that consequently the line AT, traced by a tracing-point T, fixed to the rolling curve upon the plane of the wheel, will be everywhere perpendicular to the straight line TI; so that the traced curve AT will be suitable for the flank of a tooth, in which T is the point of contact corresponding to the position I of the pitch-point. If the same rolling curve R, with the same tracing-point T, be rolled on the *outside* of any other pitch-circle, it will have the *face* of a tooth suitable to work with the *flank* AT.

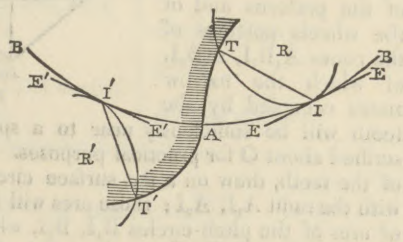

Fig. 19.

In like manner, if either the same or any other rolling curve R′ be rolled the opposite way, on the *outside* of the pitch-circle BB, so that the tracing point T′ shall start from A, it will trace the *face* AT′ of a tooth suitable to work with a *flank* traced by rolling the same curve R′ with the same tracing-point T′ *inside* any other pitch-circle.

The figure of the *path of contact* is that traced on a fixed plane by the tracing point, when the rolling curve is rotated in such a manner as always to touch a fixed straight line EIE (or E′I′E′, as the case may be) at a fixed point I (or I′).

If the same rolling curve and tracing point be used to trace both the faces and the flanks of the teeth of a number of wheels of different sizes but of the same pitch, all those wheels will work correctly together, and will form a *set*. The teeth of a *rack*, of the same set, are traced by rolling the rolling curve on both sides of a straight line.

The teeth of wheels of any figure, as well as of circular wheels, may be traced by rolling curves on their pitch-surfaces; and all teeth of the same pitch, traced by the same rolling curve with the same tracing-point, will work together correctly if their pitch-surfaces are in rolling contact.

65. *Epicycloidal Teeth.*—The most convenient rolling curve is the circle. The path of contact which it traces is identical with itself; and the flanks of the teeth are internal and their faces external epicycloids for wheels, and both flanks and faces are cycloids for a rack.

For a pitch-circle of twice the radius of the rolling or *describing* circle (as it is called), the internal epicycloid is a straight line, being, in fact, a diameter of the pitch-circle, so that the flanks of the teeth for such a pitch-circle are planes radiating from the axis. For a smaller pitch-circle the flanks would be convex and *incurved* or *under-cut*, which would be inconvenient; therefore the smallest wheel of a set should have its pitch-circle of twice the radius of the describing circle, so that the flanks may be either straight or concave.

In fig. 20, let BB′ be part of the pitch-circle of a wheel with epicycloidal teeth; CIC the line of centres; I the pitch-point; EIE′ a straight tangent to the pitch-circle at that point; R the internal, and R′ the equal external describing circles, so placed as to touch the pitch-circle and each other at I. Let DID′ be the path of contact, consisting of the arc of approach DI, and the arc of recess ID′. In order that there may always be at least two pairs of teeth in action, each of those arcs should be equal to the pitch.

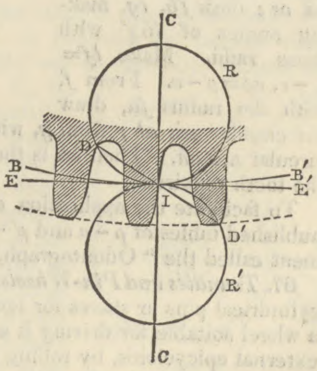

Fig. 20.

The obliquity of the action in passing the line of centres is nothing; the maximum obliquity is the angle EID = E′ID; and the mean obliquity is one-half of that angle.

It appears from experience that the mean obliquity should not exceed 15°; therefore the maximum obliquity should be about 30°; therefore the arcs DI = ID′ should each be one-sixth of a circumference; therefore the circumference of the describing circle should be *six times the pitch*.

It follows, that the smallest pinion of a set, in which pinion the flanks are straight, should have twelve teeth.

66. *Nearly Epicycloidal Teeth—Mr Willis's method.*—To facilitate the drawing of epicycloidal teeth in practice, Mr Willis has shown how to approximate to their figure by means of two circular arcs,—one concave, for the flank, the other convex, for the face; and each having for its radius the *mean* radius of curvature of the epicycloidal arc. Mr Willis's formulæ are founded on the following properties of epicycloids:—

Let R be the radius of the pitch-circle; r that of the describing circle; θ the angle made by the normal TI to the epicycloid at a given point T, with a tangent to the circle at I; that is, the obliquity of the action at T.

Then the radius of curvature of the epicycloid at T is,—

$$\left.\begin{aligned}\text{For an internal epicycloid, } \rho &= 4r\cdot\sin\theta\,\frac{R-r}{R-2r}\\ \text{For an external epicycloid, } \rho' &= 4r\cdot\sin\theta\,\frac{R+r}{R+2r}\end{aligned}\right\}\quad(37.)$$

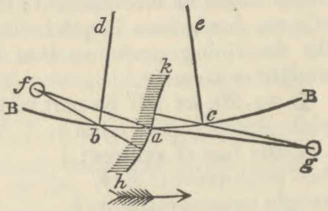
Also, to find the position of the centres of curvature relatively to the pitch-circle, we have (denoting the chord of the describing circle $\overline{TI}$ by c)—$\overline{TI}=c=2r\cdot\sin\theta$; and therefore

$$\left.\begin{aligned}\text{For the flank, } \rho-c &= 2r\cdot\sin\theta\,\frac{R}{R-2r}\\ \text{For the face, } \rho'-c &= 2r\cdot\sin\theta\,\frac{R}{R+2r}\end{aligned}\right\}\quad.\quad(38.)$$

For the proportions approved of by Mr Willis, $\sin\theta=\frac{1}{4}$ nearly; $r=p$ (the pitch) nearly; $c=\frac{p}{2}$ nearly; and if N be the number of teeth in the wheel, $\frac{r}{R}=\frac{6}{N}$ nearly; therefore approximately,

$$\left.\begin{aligned}\rho-c &= \frac{p}{2}\cdot\frac{N}{N-12}\\ \rho'-c &= \frac{p}{2}\cdot\frac{N}{N+12}\end{aligned}\right\}\quad.\quad.\quad.\quad(39.)$$

Hence the following construction (fig. 21):—Let BB be part of the pitch-circle; a the point where a tooth is to cross it. Set off $ab=ac=\frac{p}{2}$. Draw radii bd, ce; draw fb, cg, making angles of $75\frac{1}{2}$° with those radii. Make $bf=\rho-c$, $cg=\rho-c$. From f, with the radius fa, draw the circular arc ah; from g, with the radius ga, draw the circular arc ak. Then ah is the face, and ak the flank of the tooth required.



Fig, 21.

To facilitate the application of this rule, Mr Willis has published tables of $\rho-c$ and $\rho'-c$, and invented an instrument called the "Odontograph."

67. *Trundles and Pin-Wheels.*—If a wheel or trundle have cylindrical pins or staves for teeth, the faces of the teeth of a wheel suitable for driving it are described by first tracing external epicycloids, by rolling the pitch-circle of the pin-wheel or trundle on the pitch-circle of the driving-wheel, with the centre of a stave for a tracing-point, and then drawing curves parallel to, and within the epicycloids, at a distance from them equal to the radius of a stave. Trundles having only six staves will work with large wheels.

68. *Backs of Teeth and Spaces.*—Toothed wheels being in general intended to rotate either way, the *backs* of the teeth are made similar to the fronts. The *space* between two teeth, measured on the pitch-circle, is made about $\frac{1}{5}$th part wider than the thickness of the tooth on the pitch-circle; that is to say,

$$\text{Thickness of tooth} = \frac{5}{11}\text{ pitch.}$$

$$\text{Width of space} \quad = \frac{6}{11}\text{ pitch.}$$

The difference of $\frac{1}{11}$ of the pitch is called the *back-lash.* The clearance allowed between the points of teeth and the bottoms of the spaces between the teeth of the other wheel is about $\frac{1}{10}$th of the pitch.

69. *Stepped and Helical Teeth.*—Dr Hooke invented the making of the fronts of teeth in a series of steps with a view to increase the smoothness of action. A wheel thus formed resembles in shape a series of equal and similar toothed discs placed side by side, with the teeth of each a little behind those of the preceding disc. He also invented, with the same object, teeth whose fronts, instead of being parallel to the line of contact of the pitch-circles, cross it obliquely, so as to be of a screw-like or helical form. In wheel-work of this kind the contact of each pair of teeth commences at the foremost end of the helical front, and terminates at the aftermost end; and the helix is of such a pitch that the contact of one pair of teeth shall not terminate until that of the next pair has commenced.

Stepped and helical teeth have the desired effect of increasing the smoothness of motion, but they require more difficult and expensive workmanship than common teeth; and helical teeth are, besides, open to the objection that they exert a laterally oblique pressure, which tends to increase resistance, and unduly strain the machinery.

70. *Teeth of Bevel-Wheels.*—The acting surfaces of the teeth of bevel-wheels are of the conical kind, generated by the motion of a line passing through the common apex of the pitch-cones, while its extremity is carried round the outlines of the cross section of the teeth made by a sphere described about that apex.

The operations of describing the exact figures of the teeth of bevel-wheels, whether by involutes or by rolling curves, are in every respect analogous to those for describing the figures of the teeth of spur-wheels, except that in the case of bevel-wheels all those operations are to be performed on the surface of a sphere described about the apex instead of on a plane, substituting *poles* for *centres*, and *great circles* for *straight lines.*

In consideration of the practical difficulty, especially in the case of large wheels, of obtaining an accurate spherical surface, and of drawing upon it, when obtained, the following *approximate* method, proposed originally by Tredgold, is generally used:—

Let O (fig. 22) be the common apex of a pair of bevel-wheels; OB_1I, OB_2I their pitch-cones; OC_1, OC_2 their axes; OI their line of contact. Perpendicular to OI draw A_1IA_2, cutting the axes in A_1, A_2; make the outer rims of the patterns and of the wheels portions of the cones A_1B_1I, A_2B_2I, of which the narrow zones occupied by the teeth will be sufficiently near to a spherical surface described about O for practical purposes. To find the figures of the teeth, draw on a flat surface circular arcs ID_1, ID_2, with the radii A_1I, A_2I; those arcs will be the *developments* of arcs of the pitch-circles B_1I, B_2I, when the conical surfaces A_1B_1I, A_2B_2I are spread out flat. Describe the figures of teeth for the developed arcs as for a pair of spur-wheels; then wrap the developed arcs on the cones, so as to make them coincide with the pitch-circles, and trace the teeth on the conical surfaces.

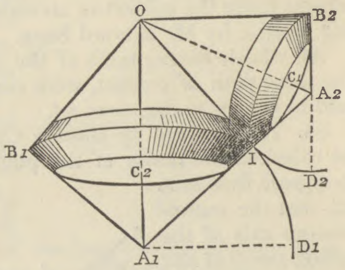


Fig. 22.

71. *Teeth of Skew-Bevel Wheels.*—The crests of the teeth of a skew-bevel wheel are parallel to the generating straight line of the hyperboloidal pitch-surface; and the transverse sections of the teeth at a given pitch-circle are similar to those of the teeth of a bevel-wheel whose pitch-surface is a cone touching the hyperboloidal surface at the given circle.

72. *Cams.*—A *cam* is a single tooth, either rotating continuously or oscillating, and driving a sliding or turning piece either constantly or at intervals. All the principles which have been stated in sect. 61 as being applicable to teeth, are applicable to cams; but in designing cams it is not usual to determine or take into consideration the form of

the ideal pitch-surface, which would give the same comparative motion by rolling contact that the cam gives by sliding contact.

73. *Screws.*—The figure of a screw is that of a convex or concave cylinder, with one or more helical projections, called *threads*, winding round it. Convex and concave screws are distinguished technically by the respective names of *male* and *female;* a short concave screw is called a *nut;* and when a *screw* is spoken of without qualification, a *convex* screw is usually understood.

The relation between the *advance* and the *rotation*, which compose the motion of a screw working in contact with a fixed screw or helical guide, has already been demonstrated in sect. 47; and the same relation exists between the magnitudes of the rotation of a screw about a fixed axis and the advance of a shifting nut in which it rotates. The advance of the nut takes places in the opposite direction to that of the advance of the screw in the case in which the nut is fixed. The *pitch* or *axial pitch* of a screw has the meaning assigned to it in that section, viz., the distance, measured parallel to the axis, between the corresponding points in two successive turns of the *same thread.* If, therefore, the screw has several equidistant threads, the true pitch is equal to the *divided axial pitch*, as measured between two adjacent threads, multiplied by the number of threads.

If a helix be described round the screw, crossing each turn of the thread at right angles, the distance between two corresponding points on two successive turns of the same thread, measured along this *normal helix*, may be called the *normal pitch;* and when the screw has more than one thread, the normal pitch from thread to thread may be called the *normal divided pitch.*

The distance from thread to thread, measured on a circle, described about the axis of the screw, called the pitch-circle, may be called the *circumferential pitch;* for a screw of one thread it is one circumference; for a screw of n threads, $\frac{\text{one circumference}}{n}$.

Let r denote the radius of the pitch circle;
n the number of threads;
θ the obliquity of the threads to the pitch circle, and of the normal helix to the axis.

$$\left.\begin{matrix} \mathrm{P}_a \\ \frac{\mathrm{P}_a}{n} = p_a \end{matrix}\right\} \text{ the axial } \left\{\begin{matrix} \text{pitch,} \\ \text{divided pitch;} \end{matrix}\right.$$

$$\left.\begin{matrix} \mathrm{P}_n \\ \frac{\mathrm{P}_n}{n} = p_n \end{matrix}\right\} \text{ the normal } \left\{\begin{matrix} \text{pitch,} \\ \text{divided pitch;} \end{matrix}\right.$$

P_c the circumferential pitch;

Then—

$$\left.\begin{aligned} p_c &= p_a \cdot \text{cotan}\,\theta = p_n \cdot \text{cosec}\,\theta = \frac{2\pi r}{n}; \\ p_a &= p_n \cdot \quad \sec\theta = p_c \cdot \quad \tan\theta = \frac{2\pi r \cdot \tan\theta}{n}; \\ p_n &= p_c \cdot \quad \sin\theta = p_a \cdot \quad \cos\theta = \frac{2\pi r \cdot \sin\theta}{n}. \end{aligned}\right\} \quad . \quad (40.)$$

If a screw rotates, the number of threads which pass a fixed point in one revolution is the number of threads in the screw.

A pair of convex screws, each rotating about its axis, are used as an elementary combination to transmit motion by the sliding contact of their threads. Such screws are commonly called *endless screws.* At the point of contact of the screws their threads must be parallel; and their line of connection is the common perpendicular to the acting surfaces of the threads at their point of contact. Hence the following principles:—

I. If the screws are both right-handed or both left-handed, the angle between the directions of their axes is the sum of their obliquities; if one is right-handed and the other left-handed, that angle is the difference of their obliquities.

II. The normal pitch for a screw of one thread, and the normal divided pitch for a screw of more than one thread, must be the same in each screw.

III. The angular velocities of the screws are inversely as their numbers of threads.

Dr Hooke's wheels with oblique or helical teeth, are in fact screws of many threads, and of large diameters as compared with their lengths.

The ordinary position of a pair of endless screws is with their axes at right angles to each other. When one is of considerably greater diameter than the other, the larger is commonly called in practice a *wheel*, the name *screw* being applied to the smaller only; but they are nevertheless both screws in fact.

To make the teeth of a pair of endless screws fit correctly and work smoothly, a hardened steel screw is made of the figure of the smaller screw, with its thread or threads notched so as to form a cutting tool; the larger screw, or "wheel," is cast approximately of the required figure; the larger screw and the steel screw are fitted up in their proper relative position, and made to rotate in contact with each other by turning the steel screw, which cuts the threads of the larger screw to their true figure.

74. *Coupling of Parallel Axes—Oldham's Coupling.*—A *coupling* is a mode of connecting a pair of shafts so that they shall rotate in the same direction with the same mean angular velocity. If the axes of the shafts are in the same straight line, the coupling consists in so connecting their contiguous ends that they shall rotate as one piece; but if the axes are not in the same straight line, combinations of mechanism are required. A coupling for parallel shafts which acts by *sliding contact* was invented by Oldham, and is represented in fig. 23. C_1, C_2 are the axes of the two parallel shafts; D_1, D_2 two discs facing each other, fixed on the ends of the two shafts respectively; $\mathrm{E}_1\mathrm{E}_1$, a bar sliding in a diametral groove in the face of D_1; $\mathrm{E}_2\mathrm{E}_2$ a bar sliding in a diametral groove in the face of D_2: those bars are fixed together at A, so as to form a rigid cross. The angular velocities of the two discs and of the cross are all equal at every instant; the middle point of the cross, at A, revolves in the dotted circle described upon the line of centres C_1 C_2 as a diameter, twice for each turn of the discs and cross; the instantaneous axis of rotation of the cross at any instant is at I, the point in the circle $\mathrm{C}_1\mathrm{C}_2$ diametrically opposite to A.

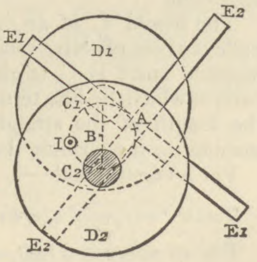

Fig. 23.

Oldham's coupling may be used with advantage where the axes of the shafts are intended to be as nearly in the same straight line as is possible, but where there is some doubt as to the practicability or permanency of their exact continuity.

75. *Wrapping Connectors—Belts, Cords, and Chains.*—Flat belts of leather or of gutta percha, round cords of catgut, hemp, or other material, and metal chains, are used as wrapping connectors to transmit rotatory motion between pairs of pulleys and drums.

Belts (the most frequently used of all wrapping connectors) require nearly cylindrical pulleys. A belt tends to move towards that part of a pulley whose radius is greatest; pulleys for belts, therefore, are slightly swelled in the middle, in order that the belt may remain on the pulley, unless forcibly shifted. A belt when in motion is shifted off a pulley, or from one pulley on to another of equal size alongside of it, by pressing against that part of the belt which is moving *towards* the pulley.

Cords require either cylindrical drums with ledges or grooved pulleys.

Chains require pulleys or drums, grooved, notched, and toothed, so as to fit the links of the chain.

Wrapping connectors for communicating continuous motion are endless.

Wrapping connectors for communicating reciprocating motion have usually their ends made fast to the pulleys or drums which they connect, and which in this case may be sectors.

The line of connection of two pieces connected by a wrapping connector is the centre line of the belt, cord, or chain; and the comparative motions of the pieces are determined by the principles of sect. 52, if both pieces turn; and of sect. 53, if one turns and the other shifts, in which latter case the motion must be reciprocating.

The *pitch-line* of a pulley or drum is a curve to which the line of connection is always a tangent; that is to say, it is a curve parallel to the acting surface of the pulley or drum, and distant from it by half the thickness of the wrapping connector.

Pulleys and drums for communicating a constant velocity-ratio are circular. The *effective radius,* or radius of the pitch-circle of a circular pulley or drum, is equal to the real radius added to half the thickness of the connector. The angular velocities of a pair of connected circular pulleys or drums are inversely as the effective radii.

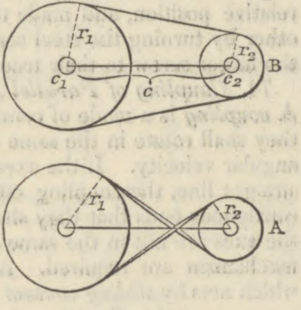

Fig. 24.

A *crossed* belt, as in fig. 24, A, reverses the direction of the rotation communicated; an *uncrossed* belt, as in fig. 24, B, preserves that direction.

The *length* L of an endless belt connecting a pair of pulleys whose effective radii are r_1, r_2, with parallel axes whose distance apart is C, is given by the following formulæ, in each of which the first term, containing the radical, expresses the length of the straight parts of the belt, and the remainder of the formula the length of the curved parts.

For a crossed belt,—

$$\mathrm{L}=2\sqrt{c^2-(r_1+r_2)^2}+(r_1+r_2)\left(\pi-2\,\mathrm{arc}\cdot\sin\frac{r_1+r_2}{c}\right) \quad . \; . \; (41\ \mathrm{A.})$$

For an uncrossed belt,—

$$\mathrm{L}=2\sqrt{\{c^2-(r_1-r_2)^2\}}+\pi(r_1-r_2)+2(r_1-r_2)\,\mathrm{arc}\cdot\sin\frac{r_1-r_2}{c} \quad (41\ \mathrm{B.})$$

in which r_1 is the greater radius, and r_2 the less.

When the axes of a pair of pulleys are not parallel, the pulleys should be so placed that the part of the belt which is *approaching* each pulley shall be in the plane of the pulley.

76. *Speed-Cones*—(See fig. 25.)—A pair of speed-cones is a contrivance for varying and adjusting the velocity-ratio communicated between a pair of parallel shafts by means of a belt. The speed-cones are either continuous cones or conoids, as A, B, whose velocity-ratio can be varied gradually while they are in motion by shifting the belt, or sets of pulleys whose radii vary by steps, as C, D, in which case the velocity-ratio can be changed by shifting the belt from one pair of pulleys to another.

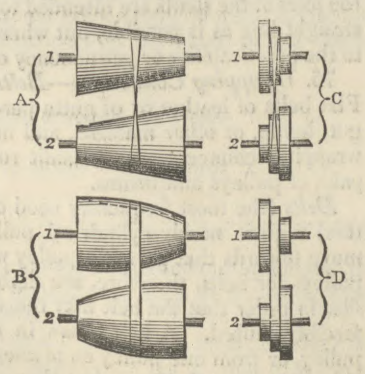

Fig. 25.

In order that the belt may fit accurately in every possible position on a pair of speed-cones, the quantity L must be constant, in equations 41 A or 41 B, according as the belt is crossed or uncrossed.

For a *crossed* belt, as in A and C, fig. 25, L depends solely on c and on r_1+r_2. Now c is constant because the axes are parallel; therefore the *sum of the radii* of the pitch-circles connected in every position of the belt is to be constant. That condition is fulfilled by a pair of continuous cones generated by the revolution of two straight lines inclined opposite ways to their respective axes at equal angles.

For an uncrossed belt, the quantity L in equation 41 B is to be made constant. The exact fulfilment of this condition requires the solution of a transcendental equation; but it may be fulfilled with accuracy sufficient for practical purposes by using, instead of 41 B, the following *approximate* equation:—

$$\mathrm{L\ nearly}=2c+\pi(r_1+r_2)+\frac{(r_1-r_2)^2}{c}. \quad \cdot \quad (42.)$$

The following is the most convenient practical rule for the application of this equation:—

Let the speed-cones be equal and similar conoids, as in B, fig. 25, but with their large and small ends turned opposite ways. Let r_1 be the radius of the large end of each, r_2 that of the small end, r_0 that of the middle; and let v be the *sagitta,* measured perpendicular to the axes, of the arc by whose revolution each of the conoids is generated, or, in other words, the *bulging* of the conoids in the middle of their length. Then

$$v=r_0-\frac{r_1+r_2}{2}=\frac{(r_1-r_2)^2}{2\pi c} \quad . \; . \; . \quad (43.)$$

$2\pi=6{\cdot}2832$; but 6 may be used in most practical cases without sensible error.

The radii at the middle and end being thus determined, make the generating curve an arc either of a circle or of a parabola.

77. *Linkwork in General.*—The pieces which are connected by linkwork, if they rotate or oscillate, are usually called *cranks, beams,* and *levers.* The *link* by which they are connected is a rigid rod or bar, which may be straight, or of any other figure; the straight figure, being the most favourable to strength, is always used when there is no special reason to the contrary. The link is known by various names under various circumstances, such as *coupling-rod, connecting-rod, crank-rod, eccentric-rod,* &c. It is attached to the pieces which it connects by two pins, about which it is free to turn. The effect of the link is to maintain the distance between the axes of those pins invariable; hence the common perpendicular of the axes of the pins is *the line of connection,* and its extremities may be called the *connected points.* In a turning piece, the perpendicular let fall from its connected point upon its axis of rotation is the *arm* or *crank-arm.*

The axes of rotation of a pair of turning pieces connected by a link are almost always parallel, and perpendicular to the line of connection; in which case the angular velocity-ratio at any instant is the reciprocal of the ratio of the common perpendiculars let fall from the line of connection upon the respective axes of rotation.

If at any instant the direction of one of the crank-arms coincides with the line of connection, the common perpendicular of the line of connection and the axis of that crank-arm vanishes, and the directional relation of the motions becomes indeterminate. The position of the connected point of the crank-arm in question at such an instant is called a *dead-point.* The velocity of the other connected point at such an instant is null, unless it also reaches a dead-point at the same instant, so that the line of connection is in the plane of the two axes of rotation, in which case the velocity-ratio is indeterminate. Examples of dead points, and of the means of preventing the inconvenience which they tend to occasion, will appear in the sequel.

78. *Coupling of Parallel Axes.*—Two or more parallel shafts (such as those of a locomotive engine, with two or more pairs of driving wheels) are made to rotate with constantly equal angular velocities by having equal cranks, which are maintained parallel by a coupling-rod of such a length that the line of connection is equal to the distance between the axes. The cranks pass their dead points simultaneously. To obviate the unsteadiness of motion which this tends to cause, the shafts are provided with a second set of cranks at right angles to the first, connected by means of a similar coupling-rod, so that one set of cranks pass their dead points at the instant when the other set are furthest from theirs.

79. *Comparative Motion of Connected Points.*—As the link is a rigid body, it is obvious that its action in communicating motion may be determined by finding the comparative motion of the connected points, according to the principles laid down in sect. 48; and this is often the most convenient method of proceeding.

If a connected point belongs to a turning piece, the direction of its motion at a given instant is perpendicular to the plane containing the axis and crank-arm of the piece. If a connected point belongs to a shifting piece, the direction of its motion at any instant is given, and a plane can be drawn perpendicular to that direction.

The line of intersection of the planes perpendicular to the paths of the two connected points at a given instant, is the *instantaneous axis of the link* at that instant; and the *velocities of the connected points are directly as their distances from that axis.*

In drawing on a plane surface, the two planes perpendicular to the paths of the connected points are represented by two lines (being their sections by a plane normal to them), and the instantaneous axis by a point (fig. 26); and should the length of the two lines render it impracticable to produce them until they actually intersect, the velocity-ratio of the connected points may be found by the principle, that it is equal to the ratio of the segments which a line parallel to the line of connection cuts off from any two lines drawn from a given point, perpendicular respectively to the paths of the connected points.

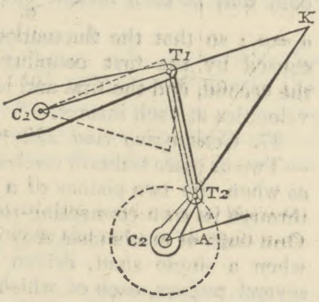

Fig. 26.

To illustrate this by one example: Let C_1 be the axis, and T_1 the connected point of the beam of a steam-engine; T_1T_2 the connecting or crank-rod; T_2 the other connected point, and the centre of the crank-pin; C_2 the axis of the crank and its shaft. Let v_1 denote the velocity of T_1 at any given instant; v_2 that of T_2. To find the ratio of these velocities, produce C_1T_1, C_2T_2, till they intersect in K; K is the instantaneous axis of the connecting rod, and the velocity-ratio is

$$v_1 : v_2 :: \overline{KT_1} : \overline{KT_2} \quad . \quad . \quad . \quad . \quad (44.)$$

Should K be inconveniently far off, draw any triangle with its sides respectively parallel to C_1T_1, C_2T_2, and T_1T_2; the ratio of the two sides first mentioned will be the velocity-ratio required. For example, draw C_2A parallel to C_1T_1, cutting T_1T_2 in A; then

$$v_1 : v_2 :: \overline{C_2A} : \overline{C_2T_2} \quad . \quad . \quad . \quad . \quad (45.)$$

80. *Eccentric.*—An eccentric circular disc fixed on a shaft, and used to give a reciprocating motion to a rod, is in effect a crank-pin of sufficiently large diameter to surround the shaft, and so to avoid the weakening of the shaft which would arise from bending it so as to form an ordinary crank. The centre of the eccentric is its connected point; and its eccentricity, or the distance from that centre to the axis of the shaft, is its crank-arm.

An eccentric may be made capable of having its eccentricity altered by means of an adjusting screw, so as to vary the extent of the reciprocating motion which it communicates.

81. *Reciprocating Pieces—Stroke—Dead Points.*—The distance between the extremities of the path of the connected point in a reciprocating piece (such as the piston of a steam-engine) is called the *stroke* or *length of stroke* of that piece. When it is connected with a continuously turning-piece (such as the crank of a steam-engine) the ends of the stroke of the reciprocating piece correspond to the *dead points* of the path of the connected point of the turning piece, where the line of connection is continuous with, or coincides with the crank-arm.

Let S be the length of stroke of the reciprocating piece, L the length of the line of connection, and R the crank-arm of the continuously turning piece. Then, if the two ends of the stroke be in one straight line with the axis of the crank,

$$S = 2R \; ; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (46.)$$

and if these ends be not in one straight line with that axis, then S, L − R, and L + R, are the three sides of a triangle, having the angle opposite S at that axis; so that if θ be the supplement of the arc between the dead points,

$$\left.\begin{aligned} S^2 &= 2(L^2+R^2) - 2(L^2-R^2)\cos\theta \\ \cos\theta &= \frac{2L^2+2R^2-S^2}{2(L^2-R^2)} \end{aligned}\right\} \quad . \quad . \quad (47.)$$

82. *Coupling of Intersecting Axes: Hooke's Universal Joint.*—Intersecting axes are coupled by a contrivance of Hooke's, known as the "universal joint," which belongs to the class of linkwork (see fig. 27). Let O be the point of intersection of the axes OC_1, OC_2, and θ their angle of inclination to each other. The pair of shafts C_1, C , terminate in a pair of forks F_1, F_2, in bearings at the extremities of which turn the gudgeons at the ends of the arms of a rectangular cross, having its centre at O. This cross is the link; the connected points are the centres of the bearings F , F_2. At each instant, each of those points moves at right angles to the central plane of its shaft and fork; therefore the line of intersection of the central planes of the two forks at any instant is the instantaneous axis of the cross, and the *velocity-ratio* of the points F_1, F_2 (which, as the forks are equal, is also the *angular velocity-ratio* of the shafts), is equal to the ratio of the distances of those points from that instantaneous axis. The *mean* value of that velocity-ratio is that of equality; for each successive *quarter-turn* is made by both shafts in the same time, but its actual value fluctuates between the limits—

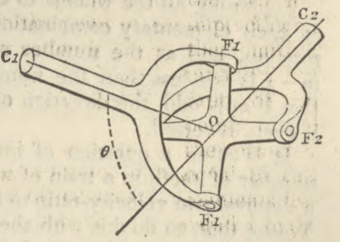

Fig. 27.

$$\left.\begin{aligned} &\frac{a_2}{a_1} = \frac{1}{\cos\theta} \text{ when } F_1 \text{ is in the plane } OC_1C_2 \\ &\text{and } \frac{a_2}{a_1} = \cos\theta \text{ when } F_2 \text{ is in that plane.} \end{aligned}\right\} \quad (48.)$$

Its value at intermediate instants is given by the following equations:—Let φ_1, φ_2 be the angles respectively made by the central planes of the forks and shafts with the plane OC_1C_2 at a given instant; then

$$\left.\begin{aligned}\cos\theta &= \tan\phi_1 \cdot \tan\phi_2 \\ \frac{\alpha_2}{\alpha_1} = -\frac{d\phi_2}{d\phi_1} &= \frac{\tan\phi_1 + \text{cotan}\,\phi_1}{\tan\phi_2 + \text{cotan}\,\phi_2}\end{aligned}\right\} \quad . \quad . \quad (49.)$$

83. *Intermittent Linkwork—Click and Ratchet.*—A *click* acting upon a ratchet-wheel or rack, which it pushes or pulls through a certain arc at each forward stroke, and leaves at rest at each backward stroke, is an example of intermittent linkwork. During the forward stroke, the action of the click is governed by the principles of linkwork; during the backward stroke that action ceases. A *catch* or *pall*, turning on a fixed axis, prevents the ratchet-wheel or rack from reversing its motion.

DIVISION V.—TRAINS OF MECHANISM.

84. *General Principles.*—*A train of mechanism* consists of a series of pieces, each of which is follower to that which drives it, and driver to that which follows it.

The comparative motion of the first driver and last follower is obtained by combining the proportions expressing by their terms the velocity-ratios, and by their signs the directional relations of the several elementary combinations of which the train consists.

85. *Trains of Wheelwork.*—Let A_1, A_2, A_3, &c., A_{m-1}, A_m, denote a series of axes; and α_1, α_2, α_3, &c., α_{m-1}, α_m, their angular velocities. Let the axis A_1 carry a wheel of N_1 teeth, driving a wheel of n_2 teeth on the axis A_2, which carries also a wheel of N_2 teeth, driving a wheel of n_3 teeth on the axis A_3, and so on; the numbers of teeth in drivers being denoted by N's, and in followers by *n*'s, and the axes to which the wheels are fixed being denoted by numbers. Then the resulting velocity-ratio is denoted by

$$\frac{\alpha_m}{\alpha_1} = \frac{\alpha_2}{\alpha_1} \cdot \frac{\alpha_3}{\alpha_2} \cdot \&\text{c.} \;.\;.\; \frac{\alpha_m}{\alpha_{m-1}} = \frac{N_1 \cdot N_2 \,..\, \&\text{c.} \,....\, N_{m-1}}{n_2 \cdot n_3 \,..\, \&\text{c.} \,....\, n_m}; \quad (50.)$$

that is to say, the velocity-ratio of the last and first axes is the ratio of the product of the numbers of teeth in the drivers to the product of the numbers of teeth in the followers.

Supposing all the wheels to be in outside gearing, then, as each elementary combination reverses the direction of rotation, and as the number of elementary combinations $m-1$ is one less than the number of axes m, it is evident that if m is odd, the direction of rotation is preserved, and, if even, reversed.

It is often a question of importance to determine the number of teeth in a train of wheels best suited for giving a determinate velocity-ratio to two axes. It was shown by Young that, to do this with the *least total number of teeth*, the velocity-ratio of each elementary combination should approximate as nearly as possible to 3·59. This would in many cases give too many axes; and, as a useful practical rule, it may be laid down that from 3 to 6 ought to be the limit of the velocity-ratio of an elementary combination in wheelwork. The smallest number of teeth in a pinion ought to be,—for epicycloidal teeth (see sect. 65), *twelve;* but it is still better, for smoothness of motion, not to go below *fifteen*, and for involute teeth the smallest number is about *twenty-four*.

Let $\frac{B}{C}$ be the velocity-ratio required, reduced to its least terms, and let B be greater than C. If $\frac{B}{C}$ is not greater than 6, and C lies between the prescribed minimum number of teeth (which may be called t), and its double $2t$, then one pair of wheels will answer the purpose, and B and C will themselves be the numbers required. Should B and C be inconveniently large, they are, if possible, to be resolved into factors, and those factors (or if they are too small, multiples of them) used for the number of teeth. Should B or C, or both, be at once inconveniently large and prime, then, instead of the exact ratio $\frac{B}{C}$, some ratio approximating to that ratio, and capable of resolution into convenient factors, is to be found by the method of continued fractions.

Should $\frac{B}{C}$ be greater than 6, the best number of elementary combinations $m-1$ will lie between

$$\frac{\log B - \log C}{\log 6} \text{ and } \frac{\log B - \log C}{\log 3}$$

Then, if possible, B and C themselves are to be resolved each into $m-1$ factors (counting 1 as a factor), which factors, or multiples of them, shall be not less than t, nor greater than $6t$; or if B and C contain inconveniently large prime factors, an approximate velocity-ratio, found by the method of continued fractions, is to be substituted for $\frac{B}{C}$ as before.

So far as the result and velocity-ratio is concerned, the *order* of the drivers N and of the followers n is immaterial; but to secure equable wear of the teeth, as explained in sect. 60, the wheels ought to be so arranged that, for each elementary combination, the greatest common divisor of N and n shall be either 1, or as small as possible.

86. *Double Hooke's Coupling.*—It has been shown in section 82 that the velocity-ratio of a pair of shafts, coupled by an universal joint, fluctuates between the limits $\cos\theta$ and $\frac{1}{\cos\theta}$. Hence one or both of the shafts must have a vibratory and unsteady motion, injurious to the mechanism and framework. To obviate this evil a short intermediate shaft is introduced, making equal angles with the first and last shaft, coupled with each of them by a Hooke's joint, and having its own two forks in the same plane. Let α_1, α_2, α_3, be the angular velocities of the first, intermediate, and last shaft in this *train of two Hooke's couplings*. Then, from the principles of sect. 82, it is evident that at each instant $\frac{\alpha_2}{\alpha_1} = \frac{\alpha_2}{\alpha_3}$, and consequently that $\alpha_3 = \alpha_1$; so that the fluctuations of angular velocity-ratio caused by the first coupling are exactly neutralized by the second, and the first and last shafts have equal angular velocities at each instant.

87. *Converging and Diverging Trains of Mechanism.*—Two or more trains of mechanism may *converge* into one; as when the two pistons of a pair of steam-engines, each through its own connecting-rod, act upon one crank-shaft. One train of mechanism may *diverge* into two or more; as when a single shaft, driven by a prime mover, carries several pulleys, each of which drives a different machine. The principles of comparative motion in such converging and diverging trains are the same as in simple trains.

DIVISION VI.—AGGREGATE COMBINATIONS.

88. *General Principles.*—Mr Willis has designated as "Aggregate Combinations" those assemblages of pieces of mechanism in which the motion of one follower is the *resultant* of component motions impressed on it by more than one driver. Two classes of aggregate combinations may be distinguished, which, though not different in their actual nature, differ in the *data* which they present to the designer, and in the method of solution to be followed in questions respecting them.

Class I. comprises those cases in which a piece A is not carried directly by the frame C, but by another piece B, *relatively* to which the motion of A is given,—the motion of the piece B relatively to the frame C being also given. Then the motion of A relatively to the frame C is the *resultant* of the motion of A relatively to B, and of B relatively to C; and that resultant is to be found by the principles already explained in Division III. of this chapter, sects. 36 to 47.

Class II. comprises those cases in which the motions of three points in one follower are determined by their connections with two or with three different drivers, so that the motion of the follower, as a whole, is to be determined by the principles of sect. 48.

This classification is founded on the kinds of problems arising from the combinations. Mr Willis adopts another classification, founded on the *objects* of the combinations, which objects he divides into two classes, viz.,—1. To produce *aggregate velocity*, or a velocity which is the resultant of two or more components in the same path; and, 2. To produce *an aggregate path;* that is, to make a given point in a rigid body move in an assigned path by communicating certain motions to other points in that body.

It is seldom that one of these effects is produced without at the same time producing the other; but the classification of Mr Willis depends upon which of those two effects, even supposing them to occur together, is the practical object of the mechanism.

89. *Reduplication of Cords—Differential Windlass—Blocks, Sheaves, and Tackle.*—The axis C carries a larger barrel AE, and a smaller barrel DB, rotating as one piece with the angular velocity a_1 in the direction AE. The pulley or *sheave* FG has a weight W hung to its centre. A cord has one end made fast to and wrapped round the barrel AE; it passes from A under the sheave FG, and has the other end wrapped round and made fast to the barrel BD. Required the relation between the velocity of translation v_2 of W, and the angular velocity a_1 of the *differential barrel.*

In this case v_2 is an *aggregate velocity*, produced by the joint action of the two drivers AE and BD, transmitted by wrapping connectors to FG, and combined by that sheave so as to act on the follower W, whose motion is the same with that of the centre of FG.

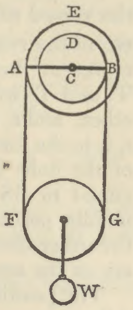

Fig. 28.

The velocity of the point F is $a_1 \cdot \overline{AC}$, *upward* motion being considered positive. The velocity of the point G is $-a_1 \cdot \overline{CB}$, *downward* motion being negative. Applying the principles of sect. 48, it appears that the instantaneous axis of the sheave FG is in the diameter FG, at the distance

$$\frac{\overline{FG}}{2} \cdot \frac{\overline{AC} - \overline{BC}}{\overline{AC} + \overline{BC}}$$

from the centre towards G; that the angular velocity of the sheave is

$$a_2 = a_1 \cdot \frac{\overline{AC} + \overline{BC}}{\overline{FG}};$$

and that, consequently, the velocity of its centre is

$$v_2 = a_2 \cdot \frac{\overline{FG}}{2} \cdot \frac{\overline{AC} - \overline{BC}}{\overline{AC} + \overline{BC}} = \frac{a_1(\overline{AC} - \overline{BC})}{2}, \quad . (51.)$$

or the *mean between the velocities of the two vertical parts of the cord.*

If the cord be fixed to the frame-work at the point B, instead of being wound on a barrel, the velocity of W is one-half of that of AF.

A case containing several sheaves is called a *block.* A *fall-block* is attached to a fixed point; a *running-block* is moveable to and from a fall-block, with which it is connected by two or more plies of a rope. The whole combination constitutes a *tackle* or *purchase.*

The two plies of a rope at opposite sides of a sheave in the fall-block have equal and opposite velocities. The two plies at opposite sides of a sheave in the running-block have velocities (as in the case of the sheave FG) differing equally in opposite directions from the velocity of the running-block.

One end of the rope is fastened either to the fall-block or the running-block. The other, or free end, is called the *fall.* Let v_1 be the velocity of the fall, v_2 that of the running-block; and let it be required to find their ratio; and let velocities towards the fall-block be positive, and from it negative.

Case 1. If the fastened end of the rope be attached to the fall-block its velocity is 0, and this also is the velocity of the first ply. The rope passes under a sheave in the running-block, so that the velocity of the second ply is $2v_2$. It then passes over a sheave in the fall-block; the velocity of the third ply is $-2v_2$; then under a sheave in the running-block; the velocity of the fourth ply is $4v_2$; and so on: the general law being this:—Let n be an *even* number, then

$$\left.\begin{array}{l} \text{The velocity of the } n^{th} \text{ ply} = nv_2; \\ \quad ,, \qquad (n+1) \cdot \text{ ply} = -nv_2 \\ = v_1, \text{ if the fall be the } (n+1)^{th} \text{ ply.} \end{array}\right\} \quad . (52.)$$

Case 2. If the fastened end of the rope be attached to the running-block, the velocity of the first ply is v_2; of the second, $-v_2$; of the third, $3v_2$; of the fourth $-3v_2$; and, generally, if n be an *odd* number,—

$$\left.\begin{array}{l} \text{Velocity of the } n^{th} \text{ ply} = nv_2 \\ \quad ,, \qquad (n+1)^{th} \text{ ply} = -nv_2 \\ = v_1, \text{ if the fall be the } (n+1)^{th} \text{ ply;} \end{array}\right\} \quad . (53.)$$

and generally,—

$$\frac{v_1}{v_2} = -n, \quad . \quad . \quad . \quad . \quad (54.)$$

where n is the *number of plies of rope by which the running-block hangs.*

The sheaves in a block are usually made all of the same diameter, and turn on a fixed pin, and they have, consequently, different angular velocities. But by making the diameter of each sheave proportional to the velocity, relatively to the block, of the ply of rope which it is to carry, the angular velocities of the sheaves in one block may be rendered equal, so that the sheaves may be made all in one piece, and may have journals turning in fixed bearings. This is called *White's tackle*, from the inventor.

For details and technical terms as to tackle and trains of tackle, see Ship-building.

90. *Differential Screw.*—On the same axis let there be two screws of the respective pitches p_1 and p_2, made in one piece, and rotating with the angular velocity a. Let this piece be called B. Let the first screw turn in a fixed nut C, and the second in a sliding nut A. The velocity of advance of B relatively to C is (according to sect. 47) ap_1; and of A relatively to B (according to sect. 73) $-ap_2$; hence the velocity of A relatively to C is

$$a(p_1 - p_2), \quad . \quad . \quad . \quad . \quad . \quad (55.)$$

being the same with the velocity of advance of a screw of the pitch $p_1 - p_2$. This combination, called *Hunter's*, or the *differential screw*, combines the strength of a large thread with the slowness of motion due to a small one.

91. *Epicyclic Trains.*—The term *epicyclic train* is used by Mr Willis to denote a train of wheels carried by an arm, and having certain rotations relatively to that arm, which itself rotates. The arm may either be driven by the wheels or assist in driving them. The comparative motions of the wheels and of the arm, and the *aggregate paths* traced by points in the wheels, are determined by the principles of the composition of rotations, and of the description of rolling curves, explained in sects. 42 to 46.

92. *Link Motion.*—Let S be the shaft of a steam-engine, O its axis, E_f the *forward eccentric*, suitably placed for

moving the slide-valve when the shaft rotates forwards, F its centre, OF its crank-arm, C_f its rod, E_b the *backward*

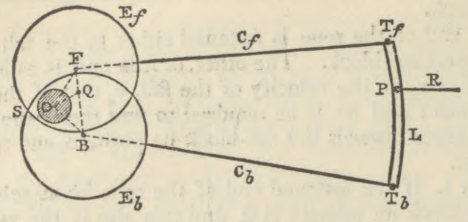

Fig. 29.

eccentric, suitably placed for moving the slide-valve when the shaft rotates backwards, B its centre, OB its crank-arm. C_b its rod. L is a long narrow box called the *link*, jointed at T_f and T_b to the eccentric rods; R is the valve-rod which works the slide-valve, jointed to P, a slider, which, either by moving L or R, or both, can be adjusted to any required position in the link. When P is at T_f, the valve is said to be in *full forward gearing*, being acted upon by E_f alone. When P is at T_b, the valve is said to be in *full backward gearing*, being acted upon by E_b alone.

When P is placed in an intermediate position, the valve has an aggregate motion due to the joint action of E_f and E_b. The most exact mode of determining that motion is to make a skeleton drawing of the apparatus in various positions; but an *approximation* to the motion of the valve may be obtained by joining FB, and taking Q, so that

$$\overline{T_fP} : \overline{T_bP} :: \overline{FQ} : \overline{BQ};$$

then the valve will move nearly as if it were worked by one eccentric, having its centre at Q.

93. *Parallel Motions—Exact.*—A *parallel motion* is a combination of turning pieces in mechanism designed to guide the motion of a reciprocating piece either exactly or approximately in a straight line, so as to avoid the friction which arises from the use of straight guides for that purpose.

Fig. 30 represents an exact parallel motion, first proposed, it is believed, by Mr Scott Russell.

The arm CD turns on the axis C, and is jointed at D to the middle of the bar ADB, whose length is double of that of CD, and one of whose ends B is jointed to a slider, sliding in straight guides along the line CB. Draw BE perpendicular to CB, cutting CD produced in E, then E is the instantaneous axis of the bar ADB; and the direction of motion of A is at every instant perpendicular to EA; that is, along the straight line AC*a*. While the stroke of A is AC*a* extending to equal distances on either side of C, and equal to twice the chord of the arc D*d*, the stroke of B is only equal to twice the sagitta; and thus A is guided through a comparatively long stroke by the sliding of B through a comparatively short stroke, and by rotatory motions at the joints C, D, B. (For details, see STEAM ENGINE.)

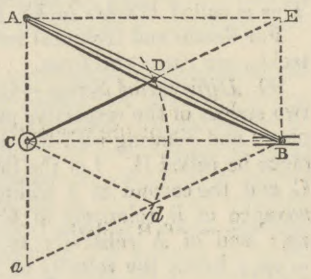

Fig. 30.

94. *Parallel Motion—Watt's Approximate.*—(See fig. 31.)—Let CT, *ct* be a pair of levers connected by a link T*t*, and oscillating about the axes C*c*, between the positions marked 1 and 3. Let the middle positions of the levers CT_2, ct_2 be parallel to each other. It is required to find a point P in the link T*t*, such that its middle position P_2, and its extreme positions P_1, P_3, shall be in the same straight line SS, perpendicular to CT_2, ct_2, and so to place the axes C, *c* on the lines CT_2, ct_2, that the path of P between the positions P_1, P_2, P_3, shall be as near as possible to a straight line.

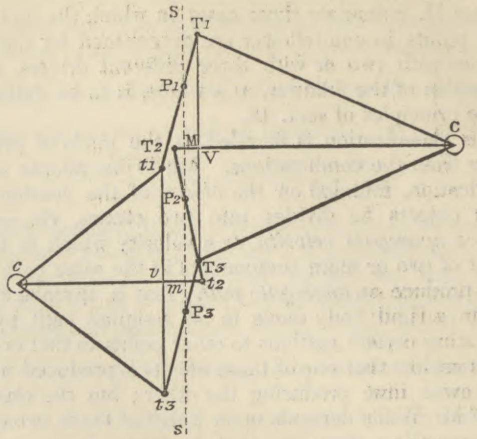

Fig. 31.

The axes C, *c* are to be so placed that the middle M of the versed sine VT_2, and the middle *m* of the versed sine vt_2, of the respective arcs whose equal chords $\overline{T_1T_3} = \overline{t_1t_3}$ represent the stroke, may each be in the line SS. Then T_1 and T_3 will be as far to one side of SS as T_2 is to the other, and t_1 and t_3 will be as far to the latter side of SS as t_2 is to the former; consequently, the two extreme positions of the links T_1t_1, T_3t_3 are parallel to each other, and inclined to SS at the same angle in one direction that the middle position of the link T_2t_2 is inclined to that line in the other direction; and the three intersections P_1, P_2, P_3, are at the same point on the link.

The position of the point P on the link is found by the following proportional equation:—

$$\left.\begin{array}{r}\overline{Tt} : \overline{PT} : \overline{Pt}\\ :: \overline{TV} + \overline{tv} : \overline{TV} : \overline{tv}\\ :: \overline{CM} + \overline{cm} : \overline{cm} : \overline{CM}\end{array}\right\} \quad . \quad (56.)$$

Suppose the axes C, *c* to be given, the line of stroke SS, and the length of stroke $L = T_1T_3 = t_1t_3$, and that it is required to find the dimensions of the levers and link. Let fall CM and $cm \perp$ SS; then

$$\left.\begin{array}{l}\overline{TV} = \dfrac{L^2}{8\,\overline{CM}}; \ tv = \dfrac{L^2}{8\,\overline{cm}};\\ \overline{CT} = \overline{CM} + \frac{1}{2}\overline{TV}; \ \overline{ct} = cm + \frac{1}{2}tv;\\ \overline{Tt} = \sqrt{\left\{L^2 + \dfrac{(\overline{TV} + \overline{tv})}{4}\right\}}\end{array}\right\} \quad . \quad (57.)$$

If C and *c* are at the same side of SS, the smaller of the two perpendiculars is to be treated as negative in the formulæ, and the difference of the versed sines used instead of their sum; and the point P will lie in the *prolongation* of the link beyond T*t* to the side of the longer lever. When the arcs of oscillation of the levers on either side of their middle positions do not exceed 20°, the intermediate portions of the path of P between P_1, P_2, and P_3, are near enough to a straight line for practical purposes; and that point may be used to guide a sliding piece, such as the piston-rod of a steam-engine, for which purpose this parallel motion was originally invented by Watt. (For details respecting the various modes of practically applying it, see STEAM ENGINE.)

CHAPTER II.—ON APPLIED DYNAMICS.

95. *Laws of Motion.*—The action of a machine in transmitting *force* and *motion* simultaneously, or performing *work*, is governed, in common with the phenomena of moving

bodies in general, by two "laws of motion," with respect to the proof of which, see DYNAMICS. They are as follows:—

LAW I. A body under the action of no force, or of mutually balanced forces, either remains at rest or moves in a straight line with an uniform velocity.

LAW II. The *deviation* of the motion of a given mass, caused in a given time by a given unbalanced force, takes place in the direction of the force, and is proportional to the magnitude of the force and the time during which it acts directly, and inversely to the mass.

(As to the determination of *deviations*, see sects. 25, 26, 27.)

The law of the *equality of action and reaction* is sometimes added as a "third law of motion;" but it is properly to be classed as a *law of force*, whether balanced or unbalanced; being equivalent to the statement that *every force is a pair of actions of equal magnitudes and opposite directions exerted mutually between a pair of bodies.*

96. *Comparison of Deviating Force with Gravity.*—A body's own weight,—that is, its tendency to approach the earth,—acting unbalanced on the body, produces deviation at a rate per second denoted by the symbol g, whose numerical value is as follows:—Let λ denote the latitude of the place, h its elevation above the mean level of the sea; $g_1 = 32{\cdot}169545$ feet per second, the value of g for $\lambda = 45^\circ$ and $h = 0$; and $R = 20887540^{ft.}\,(1 + 0{\cdot}00164 \cos 2\lambda)$, the earth's radius at the locality of observation. Then

$$g = g_1 \cdot (1 - 0{\cdot}00284 \cos 2\lambda) \cdot \left(1 - \frac{2h}{R}\right) \quad . \quad (58.)$$

For latitudes exceeding 45° it is to be borne in mind that $\cos 2\lambda$ is negative, and the terms containing it as their factor have their signs reversed.

For practical purposes connected with ordinary machines it is sufficiently accurate to assume

$$g = 32{\cdot}2 \text{ feet per second nearly.} \quad . \quad . \quad . \quad (59.)$$

If, then, a body of the weight w be deviated by an unbalanced force f expressed in *units of weight*, the deviation produced in a second will be

$$\frac{fg}{w} \quad . \quad . \quad . \quad (60.)$$

$\frac{w}{g}$ is sometimes called the *mass*, or *inertia* of the body.

97. *Deviating Forces Classed: Deflecting Force—Accelerating and Retarding Forces.*—The forces to be specially considered, in treating of machines as distinguished from structures, act upon bodies already in motion, and may be resolved into components and classed with reference to their directions as compared with the directions of motions of the bodies.

A force acting on a body in a direction at *right angles to its path*, produces *lateral deviation or deflection of the path* alone, without change of velocity. Such a force may be called a *deflecting force.*

A force acting in the direction of the body's path produces *acceleration* or *retardation* according as it acts *with* or *against* the motion of the body, but no deflection.

98. *Division of the Subject.*—On this classification of the deviating forces in machines is founded the following division of the subject of dynamics as applied to machines:—

Division I. Balanced forces in machines of uniform velocity.
Division II. Deflecting forces in such machines.
Division III. Working of machines of varying velocity.

DIVISION I.—BALANCED FORCES IN MACHINES OF UNIFORM VELOCITY.

99. *Application of Force to Mechanism.*—Forces are expressed in units of weight; and the unit most commonly employed in Britain is the *pound avoirdupois.* The action of a force applied to a body is always in reality distributed over some definite space, either a volume of three dimensions, or a surface of two. An example of a force distributed throughout a volume is the *weight* of the body itself, which acts on every particle, how small soever. The *pressure* exerted between two bodies at their surface of contact, or between the two parts of one body on either side of an ideal surface of separation, is an example of a force distributed over a surface. The mode of distribution of a force applied to a solid body requires to be considered when its stiffness and strength are treated of; but in questions respecting the action of a force upon a rigid body considered as a whole, the *resultant* of the distributed force, determined according to the principles of statics (*q. v.*), and considered as acting in a *single line* and applied at a *single point*, may, for the occasion, be substituted for the force as really distributed. Thus, the weight of each separate piece in a machine is treated as acting wholly at its *centre of gravity*, and each pressure applied to it as acting at a point called the *centre of pressure* of the surface to which the pressure is really applied.

100. *Forces applied to Mechanism Classed.*—If θ be the *obliquity* of a force F applied to a piece of a machine,—that is, the angle made by the direction of the force with the direction of motion of its point of application,—then, by the principles of statics (*q. v.*), F may be resolved into two rectangular components, viz.:—

$$\left.\begin{array}{l}\text{Along the direction of motion, } P = F \cdot \cos\theta \\ \text{Across the direction of motion, } Q = F \cdot \sin\theta\end{array}\right\} \quad (61.)$$

If the component along the direction of motion acts *with* the motion, it is called an *effort*; if *against* the motion, a *resistance.* The component *across* the direction of motion is a *lateral pressure;* the unbalanced lateral pressure on any piece, or part of a piece, is *deflecting force.* A lateral pressure may increase resistance by causing friction: the friction so caused acts against the motion, and is a resistance; but the lateral pressure causing it is not a resistance. Resistances are distinguished into *useful* and *prejudicial*, according as they arise from the useful effect produced by the machine or from other causes.

101. *Work.*—*Work* consists in moving against resistance. The work is said to be *performed*, and the resistance *overcome.* Work is measured by the product of the resistance into the distance through which its point of application is moved. The *unit of work* commonly used in Britain is a resistance of one pound overcome through a distance of one foot, and is called a *foot-pound.*

Work is distinguished into *useful work* and *prejudicial* or *lost work*, according as it is performed in producing the useful effect of the machine, or in overcoming prejudicial resistance.

102. *Energy—Potential Energy.*—*Energy* means *capacity for performing work.* The *energy of an effort*, or *potential energy*, is measured by the product of the effort into the distance through which its point of application is *capable* of being moved. The unit of energy is the same with the unit of work.

When the point of application of an effort *has been moved* through a given distance, energy is said to have been *exerted* to an amount expressed by the product of the effort into the distance through which its point of application has been moved.

103. *Variable Effort and Resistance.*—If an effort has different magnitudes during different portions of the motion of its point of application through a given distance, let each different magnitude of the effort P be multiplied by the length Δs of the corresponding portion of the path of the point of application; the sum

$$\Sigma \cdot P \Delta s \quad . \quad . \quad . \quad . \quad . \quad . \quad (62.)$$

is the whole energy exerted. If the effort varies by insensible gradations, the energy exerted is the integral or limit towards which that sum approaches continually as the divisions of the path are made smaller and more numerous, and is expressed by

$$\int \mathrm{P}ds. \quad . \quad . \quad . \quad . \quad . \quad . \quad (63.)$$

Similar processes are applicable to the finding of the work performed in overcoming a varying resistance.

104. *Dynamometer or Indicator.*—A dynamometer or indicator is an instrument which measures and records the energy exerted by an effort. It usually consists essentially, first, of a piece of paper moving with a velocity proportional to that of the point of application of the effort, and having a straight line marked on it parallel to its direction of motion, called the zero line; and secondly, of a spring acted upon and bent by the effort, and carrying a pencil whose perpendicular distance from the zero line, as regulated by the bending of the spring, is proportional to the effort. The pencil traces on the piece of paper a line such that its *ordinate* perpendicular to the zero line at a given point represents the effort P for the corresponding point in the path of the point of effort, and the *area between two ordinates* represent the energy exerted $\int \mathrm{P}ds$, for the corresponding portion of the path of the point of effort.

105. *Principle of the Equality of Energy and Work.*—From the first law of motion it follows, that in a machine whose pieces move with uniform velocities the efforts and resistances must balance each other. Now from the laws of statics (*q.v.*) it is known, that, in order that a system of forces applied to a system of connected points may be in equilibrio, it is necessary that the sum formed by putting together the products of the forces by the respective distances through which their points of application are capable of moving simultaneously, each along the direction of the force applied to it, shall be zero; products being considered positive or negative according as the direction of the forces and the possible motions of their points of application are the same or opposite.

In other words, the sum of the negative products is equal to the sum of the positive products. This principle, applied to a machine whose parts move with uniform velocities, is equivalent to saying, that in any given interval of time *the energy exerted is equal to the work performed.*

The symbolical expression of this law is as follows:—Let efforts be applied to one or to any number of points of a machine; let any one of these efforts be represented by P, and the distance traversed by its point of application in a given interval of time by ds; let resistances be overcome at one or any number of points of the same machine; let any one of these resistances be denoted by R, and the distance traversed by its point of application in the given interval of time by ds^1; then

$$\Sigma{\cdot}\mathrm{P}ds = \Sigma{\cdot}\mathrm{R}ds^1 \quad . \quad . \quad . \quad . \quad (64.)$$

The lengths ds, ds^1 are proportional to the velocities of the points to whose paths they belong, and the proportions of those velocities to each other are deducible from the construction of the machine by the principles of pure mechanism explained in chapter I.

106. *Efficiency.*—The *efficiency* of a machine is the ratio of the *useful* work to the *total* work, that is, to the energy exerted,—and is represented by

$$\frac{\Sigma{\cdot}\mathrm{R}_u ds^1}{\Sigma{\cdot}\mathrm{R}ds^1} = \frac{\Sigma{\cdot}\mathrm{R}_u ds^1}{\Sigma{\cdot}\mathrm{R}_u ds^1 + \Sigma{\cdot}\mathrm{R}_p ds^1} = \frac{\Sigma{\cdot}\mathrm{R}_u ds^1}{\Sigma{\cdot}\mathrm{P}ds} = \frac{\mathrm{U}}{\mathrm{E}} \quad (65.)$$

R_u being taken to represent useful, and R_p prejudicial resistances.

The more nearly the efficiency of a machine approaches to unity, the better is the machine.

107. *Power and Effect.*—The *power* of a machine is the energy exerted, and the *effect*, the useful work performed, in some interval of time of definite length, such as a second, a minute, an hour, or a day.

The unit of power, called conventionally a *horse-power*, is 550 foot-pounds per second, or 33,000 foot-pounds per minute, or 1,980,000 foot-pounds per hour.

108. *Modulus of a Machine.*—In the investigation of the properties of a machine, the useful resistances to be overcome and the useful work to be performed are usually given. The prejudicial resistances are generally functions of the useful resistances of the weights of the pieces of the mechanism, and of their form and arrangement; and having been determined, they serve for the computation of the *lost* work, which, being added to the useful work, gives the expenditure of energy required. The result of this investigation, expressed in the form of an equation between the energy and the useful work, is called by Mr Moseley the *modulus* of the machine. The general form of the modulus of a machine may be expressed thus

$$\mathrm{E} = \mathrm{U} + \varphi(\mathrm{U}, \mathrm{A}) + \psi(\mathrm{A}), \quad . \quad . \quad . \quad (66.)$$

where A denotes some quantity or set of quantities depending on the form, arrangement, weight, and other properties of the mechanism. Mr Moseley, however, has pointed out that in most cases this equation takes the much more simple form of

$$\mathrm{E} = (1 + \mathrm{A})\mathrm{U} + \mathrm{B}, \quad . \quad . \quad . \quad . \quad (67.)$$

where A and B are *constants*, depending on the form, arrangement, and weight of the mechanism. The efficiency corresponding to the last equation is

$$\frac{\mathrm{U}}{\mathrm{E}} = \frac{1}{1 + \mathrm{A} + \frac{\mathrm{B}}{\mathrm{U}}}. \quad . \quad . \quad . \quad . \quad (68.)$$

109. *Trains of Mechanism.*—In applying the preceding principles to a train of mechanism, it may either be treated as a whole, or it may be considered in sections consisting of single pieces, or of any convenient portion of the train; each section being treated as a machine driven by the effort applied to it and energy exerted upon it through its line of connection with the preceding section, performing useful work by driving the following section, and losing work by overcoming its own prejudicial resistances.

It is evident that *the efficiency of the whole train is the product of the efficiencies of its sections.*

110. *Rotating Pieces: Couples of Forces.*—It is often convenient to express the energy exerted upon, and the work performed by, a turning piece in a machine, in terms of the *moment* of the *couples of forces* acting on it, and of the angular velocity. A *couple* of forces consists of two forces equal in magnitude and opposite in direction, but not acting in the same line (as P_1, P_2, in fig. 32). The perpendicular distance between the lines of action of the forces is the *leverage* or *arm* of the couple (as $\overline{\mathrm{AB}}$). The tendency of a couple is to turn the body to which it is applied about an axis perpendicular to the plane containing the couple and its arm, and the magnitude of that tendency, called the *moment* of the couple, is measured by the product of the common magnitude of the forces into the length of their arm. That is to say, let $\mathrm{P} = \mathrm{P}_1 = \mathrm{P}_2$, $\overline{\mathrm{AB}} = r$; then the movement is

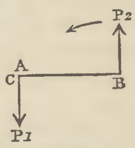

Fig. 32.

$$\mathrm{M} = \mathrm{P}r. \quad . \quad . \quad . \quad . \quad . \quad (69.)$$

The ordinary British unit of moment is a *foot-pound;* but it is to be remembered that this is a foot-pound of a different sort from the unit of energy and work.

If a force be applied to a turning piece in a line not passing through its axis, the axis will press against its bearings with an equal and parallel force, and the equal and opposite reaction of the bearings will constitute, together with the first-mentioned force, a couple whose arm is the perpendicular distance from the axis to the line of action of the first force.

A couple is said to be *right* or *left handed* with reference to the observer, according to the direction in which it tends to turn the body, and is a *driving* couple, or a *resisting* couple according as its tendency is with or against that of the actual rotation.

Let dt be an interval of time, a the angular velocity of the piece; then adt is the angle through which it turns in the interval dt, and $ds=vdt=radt$ is the distance through which the point of application of the force moves. Let P represent an effort, so that $\mathrm{P}r$ is a driving couple, then

$$\mathrm{P}ds=\mathrm{P}vdt=\mathrm{P}radt=\mathrm{M}adt \quad . \ . \ . \quad (70.)$$

is the energy exerted by the couple M in the interval dt; and a similar equation gives the work performed in overcoming a resisting couple. When several couples act on one piece, the resultant of their moments is to be multiplied by the common angular velocity of the whole piece.

111. *Reduction of Forces to a given Point, and of Couples to the Axis of a given Piece.*—In computations respecting machines it is often convenient to substitute for a force applied to a given point, or a couple applied to a given piece, the *equivalent* force or couple applied to some other point or piece; that is to say, the force or couple, which, if applied to the other point or piece, would exert equal energy or employ equal work. The principles of this reduction are, that the ratio of the given to the equivalent force is the reciprocal of the ratio of the velocities of their points of application; and the ratio of the given to the equivalent couple is the reciprocal of the ratio of the angular velocities of the pieces to which they are applied.

These velocity-ratios are known by the construction of the mechanism, and are independent of the absolute speed.

112. *Balanced Lateral Pressure of Guides and Bearings.*—The most important part of the lateral pressure on a piece of mechanism is the reaction of its guides, if it is a sliding piece, or of the bearings of its axis, if it is a turning piece; and the balanced portion of this reaction is equal and opposite to the resultant of all the other forces applied to the piece, its own weight included. There may or may not be an unbalanced component in this pressure, due to deviated motion. Its laws will be considered in the sequel.

113. *Friction—Unguents.*—The most important kind of resistance in machines is the *friction* or *rubbing resistance* of surfaces which slide over each other. The *direction* of the resistance of friction is opposite to that in which the sliding takes place. Its *magnitude* is the product of the *normal pressure* or force which presses the rubbing surfaces together in a direction perpendicular to themselves, into a specific constant already mentioned in part I., sect. 14, as the *coefficient of friction*, which depends on the nature and condition of the surfaces and of the unguent, if any, with which they are covered. The *total pressure* exerted between the rubbing surfaces is the resultant of the normal pressure and of the friction, and its *obliquity*, or inclination to the common perpendicular of the surfaces, is the *angle of repose* formerly mentioned in sect. 14, whose tangent is the coefficient of friction. Thus, let N be the normal pressure, R the friction, T the total pressure, f the coefficient of friction, and ϕ the angle of repose; then

$$\left.\begin{array}{c} f=\tan\phi\,; \\ \mathrm{R}=f\mathrm{N}=\mathrm{N}\tan\phi=\mathrm{T}\sin\phi\,; \end{array}\right\} \quad \cdot \ \cdot \quad (71.)$$

Experiments on friction have been made by Coulomb, Vince, Rennie, Wood, D. Rankine, and others. The most complete and elaborate experiments are those of Morin, published in his *Notions Fondamentales de Mécanique*, and republished in Britain in the works of Moseley and Gordon. The following is an exceedingly condensed abstract of the most important results, as regards machines, of these experiments:—

Surfaces.	*f.*
Wood on wood, dry	0·25 to 0·5
Do., soaped	0·2
Metals on oak, dry	0·5 to 0·6
Do., wet	0·24 to 0·26
Do., soaped	0·2
Do. on elm, dry	0·2 to 0·25
Hemp on oak, dry	0·53
Do., wet	0·33
Leather on oak, wet or dry	0·27 to 0·35
Leather on metals, dry	0·56
Do., wet	0·36
Do., greasy	0·23
Do., oiled	0·15
Metals on metals, dry	0·15 to 0·2
Do., wet	0·30
Smooth Surfaces with Unguents—	
Occasionally greased	0·07 to 0·08
Well greased	0·05
Do., best results	0·03 to 0·036

It is to be understood that the above-stated law of friction is true for dry surfaces, only when the pressure is not sufficient to indent or abrade the surfaces; and for greased surfaces, when the pressure is not sufficient to force out the unguent from between the surfaces. If the proper limit be exceeded, the friction increases more rapidly than in the simple ratio of the normal pressure.

The limit of pressure for unguents diminishes as the speed increases; and the following are some of its approximate values as inferred from the results of experience in railway, locomotive, and carriage axles:—

Velocity of rubbing in feet per second	1	$2\frac{1}{3}$	5
Intensity of normal pressure per lb. per square inch of surface	392	224	140

In pivots, the intensity of the pressure is usually fixed at about one ton per square inch.

Unguents should be comparatively thick for heavy pressures, that they may resist being forced out; and comparatively thin for light pressures, that their viscidity may not add to the resistance.

Unguents are of three classes, viz.:—

1. *Fatty*; consisting of animal or vegetable fixed oils, such as tallow, lard, lard-oil, seal-oil, whale-oil, olive-oil. *Drying* oils, which absorb oxygen and harden, are obviously unfit for unguents.

2. *Soapy*; composed of fatty oil, alkali, and water. The best grease of this class should not contain more than about 25 or 30 per cent. of water; bad kinds contain 40 or 50 per cent. The additional water diminishes the cost, but spoils the unguent.

3. *Bituminous*; composed of solid and liquid mineral compounds of hydrogen and carbon.

114. *Work of Friction—Moment of Friction.*—The work performed in an unit of time in overcoming the friction of a pair of surfaces is the product of the friction by the velocity of sliding of the surfaces over each other, if that is the same throughout the whole extent of the rubbing surfaces. If that velocity is different for different portions of the rubbing surfaces, the velocity of each portion is to be multiplied by the friction of that portion, and the results summed or integrated.

When the relative motion of the rubbing surfaces is one of rotation, the work of friction in an unit of time, for a portion of the rubbing surfaces at a given distance from the axis of rotation, may be found by multiplying together the friction of that portion, its distance from the axis, and the angular velocity. The product of the force of friction by the distance at which it acts from the axis of rotation is called the *moment of friction*. The total moment of friction of a pair of rotating rubbing surfaces is the sum or integral of the moments of friction of their several portions.

To express this symbolically, let du represent the area of a portion of a pair of rubbing surfaces at the distance r from the axis of their relative rotation; p the intensity of the normal pressure at du per unit of area; and f the coefficient of friction. Then the moment of friction of du is

$$\left.\begin{array}{l} \qquad fprdu, \\ \text{the total moment of friction,} \\ \qquad f\int pr\cdot du; \\ \text{and the work performed in an unit of} \\ \text{time in overcoming friction, when the} \\ \text{angular velocity is } a, \\ \qquad af\int pr\cdot du. \end{array}\right\} \quad . \quad . \quad . \quad (72.)$$

It is evident that the moment of friction, and the work lost by being performed in overcoming friction, are less in a rotating piece as the bearings are of smaller radius. But a limit is put to the diminution of the radii of journals and pivots by the conditions of durability and of proper lubrication stated in sect. 113, and also by conditions of strength and stiffness.

115. *Total Pressure between Journal and Bearing.*—A single piece rotating with an uniform velocity has four mutually balanced forces applied to it: the effort exerted on it by the piece which drives it; the resistance of the piece which follows it,—which may be considered for the purposes of the present question as useful resistance; its weight, and the reaction of its own cylindrical bearings. There are given the following data:—

The direction of the effort.
The direction of the useful resistance.
The weight of the piece and the direction in which it acts.
The magnitude of the useful resistance.
The radius of the bearing r.
The angle of repose φ, corresponding to the friction of the journal on the bearing.

And there are required—

The direction of the reaction of the bearing.
The magnitude of that reaction.
The magnitude of the effort.

Let the useful resistance and the weight of the piece be compounded by the principles of statics into one force, and let this be called *the given force*.

The directions of the effort and of the given force are either parallel or meet in a point. If they are parallel, the direction of the reaction of the bearing is also parallel to them; if they meet in a point, the direction of the reaction traverses the same point.

Also, let AAA, fig. 33, be a section of the bearing, C its axis; then the direction of the reaction, at the point where it intersects the circle AAA, must make the angle ϕ with the radius of that circle; that is to say, it must be a line such as PT touching the smaller circle BB, whose radius is $r\cdot\sin\phi$. The side on which it touches that circle is determined by the fact that the obliquity of the reaction is such as to oppose the rotation.

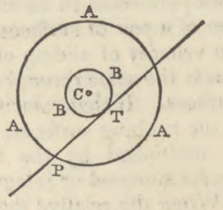

Fig. 33.

Thus is determined the direction of the reaction of the bearing; and the magnitude of that reaction and of the effort are then found by the principles of the equilibrium of three forces, already stated in part I., sect. 8, and proved in the article STATICS.

The work lost in overcoming the friction of the bearing is the same with that which would be performed in overcoming at the circumference of the small circle BB a resistance equal to the whole pressure between the journal and bearing.

In order to diminish that pressure to the smallest possible amount, the effort, and the resultant of the useful resistance, and the weight of the piece (called above, the "given force"), ought to be opposed to each other as directly as is practicable consistently with the purposes of the machine.

116. *Frictions of Pivots and Collars.*—When a shaft is acted upon by a force tending to shift it lengthways, that force must be balanced by the reaction of a bearing against a *pivot* at the end of the shaft; or, if that be impossible, against one or more *collars*, or rings *projecting* from the body of the shaft. The bearing of a pivot is called a *step* or *footstep*. Pivots require great hardness, and are usually made of steel. The *flat* pivot is a cylinder of steel having a plane circular end as a rubbing surface. Let N be the total pressure sustained by a flat pivot of the radius r; if that pressure be uniformly distributed, which is the case when the rubbing surfaces of the pivot and its step are both true planes, the *intensity* of the pressure is

$$p=\frac{\text{N}}{2\pi r^2}, \quad . \quad . \quad . \quad . \quad . \quad (73.)$$

and introducing this value into equation 72, the *moment of friction of the flat pivot* is found to be

$$\frac{2}{3}f\,\text{N}r, \quad . \quad . \quad . \quad . \quad . \quad (74.)$$

or two-thirds of that of a cylindrical journal of the same radius under the same normal pressure.

The friction of a *conical* pivot exceeds that of a flat pivot of the same radius, and under the same pressure, in the proportion of the side of the cone to the radius of its base.

The moment of friction of a *collar* is given by the formula—

$$\frac{2}{3}f\,\text{N}\frac{r^3-r'^3}{r^2-r'^2}, \quad . \quad . \quad . \quad . \quad (75.)$$

where r is the external, and r' the internal radius.

In the *cup and ball* pivot the end of the shaft and the step present two recesses facing each other, into which are fitted two shallow cups of steel or hard bronze. Between the concave spherical surfaces of those cups is placed a steel ball, being either a complete sphere, or a lens having convex surfaces of a somewhat less radius than the concave surfaces of the cups. The moment of friction of this pivot is at first almost inappreciable from the extreme smallness of the radius of the circles of contact of the ball and cups; but as they wear, that radius and the moment of friction increase.

It appears that the rapidity with which a rubbing surface wears away is proportional, jointly to the friction and to the velocity, or nearly so. Hence the pivots already mentioned wear unequally at different points, and tend to alter their figures. Mr Schiele has invented a pivot which preserves its original figure by wearing equally at all points in a direction parallel to its axis. The following are the principles on which this equality of wear depends:—

The rapidity of wear of a surface measured in an *oblique* direction is to the rapidity of wear measured normally as the secant of the obliquity is to unity. Let OX (fig. 34) be the axis of a pivot, and let RPC be a portion of a curve such, that at any point P the secant of the obliquity to the normal of the curve of a line parallel to the axis is inversely proportional to the ordinate PY, to which the velocity of P is proportional. The rotation of that curve round OX will generate the form of pivot required. Now, let PT be a tangent to the curve at P, cutting OX in

T; $\overline{PT}=\overline{PY}\times$ *secant obliquity*, and this is to be a constant quantity; hence the curve is that known as the *tractory* of the straight line OX, in which $\overline{PT}=\overline{OR}=$constant. This curve is described by having a fixed straight edge parallel to OX, along which slides a slider carrying a pin whose centre is T. On that pin turns an arm, carrying at the point P a tracing-point, pencil, or pen. Should the pen have a nib of two jaws, like those of an ordinary drawing-pen, the plane of the jaws must pass through PT. Then, while T is slid along the axis from O towards X, P will be drawn after it from R towards C along the tractory. This curve, being an asymptote to its axis, is capable of being indefinitely prolonged towards X; but in designing pivots it should stop before the angle PTY becomes less than the angle of repose of the rubbing surfaces, otherwise the pivot will be liable to stick in its bearing.

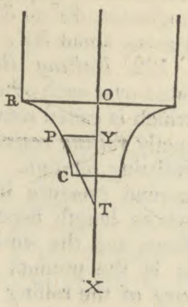

Fig 34.

The moment of friction of "Schiele's Anti-friction Pivot," as it is called, is equal to that of a cylindrical journal of the radius $\overline{OR}=\overline{PT}$ the constant tangent, under the same pressure

117. *Friction of Teeth.*—Let N be the normal pressure exerted between a pair of teeth of a pair of wheels; *s* the total distance through which they slide upon each other; *n* the number of pairs of teeth which pass the plane of axis in a unit of time. Then

$$nfNs \quad . \quad . \quad . \quad . \quad . \quad . \quad (76.)$$

is the work lost in unity of time by the friction of the teeth. The sliding *s* is composed of two parts, which take place during the approach and recess respectively. Let those be denoted by s_1 and s_2, so that $s=s_1+s_2$. In sec. 61 the *velocity* of sliding at any instant has been given, viz., $u=c\,(a_1+a_2)$, where u is that velocity, c the distance $\overline{TI}$ at any instant from the point of contact of the teeth to the pitch-point, and a_1, a_2 the respective angular velocities of the wheels.

Let v be the common velocity of the two pitch-circles, r_1, r_2 their radii; then the above equation becomes

$$u=cv\left(\frac{1}{r_1}+\frac{1}{r_2}\right)$$

To apply this to involute teeth, let c_1 be the length of the approach; c_2 that of the recess; u_1 the *mean* velocity of sliding during the approach, u_2 that during the recess. Then

$$u_1=\frac{c_1v}{2}\left(\frac{1}{r_1}+\frac{1}{r_2}\right);\ u_2=\frac{cv}{2}\left(\frac{1}{r_1}+\frac{1}{r_2}\right)$$

also, let θ be the obliquity of the action; then the times occupied by the approach and recess are respectively

$$\frac{c_1}{v\cos\theta},\ \frac{c_2}{v\cos\theta};$$

giving, finally, for the length of sliding between each pair of teeth,

$$s=s_1+s_2=\frac{c_1^{\,2}+c_2^{\,2}}{2\cos\theta}\left(\frac{1}{r_1}+\frac{1}{r_2}\right). \quad . \quad . \quad (77.)$$

which, being substituted in equation 76, gives the work lost in a unit of time by the friction of involute teeth. This result, which is exact for involute teeth, is approximately true for teeth of any figure.

For inside gearing, if r_1 be the less radius and r_2 the greater, $\frac{1}{r_1}-\frac{1}{r_2}$ is to be substituted for $\frac{1}{r_1}+\frac{1}{r_2}$.

118. *Friction of Cords and Belts.*—A flexible band, such as a cord, rope, belt, or strap, may be used either to exert an effort or a resistance upon a pulley round which it wraps. In either case the tangential force, whether effort or resistance, exerted between the band and the pulley is their mutual friction, caused by and proportional to the normal pressure between them.

Let T_1 be the tension of the free part of the band at that side *towards* which it tends to draw the pulley, or *from* which the pulley tends to draw it; T_2 the tension of the free part at the other side; T the tension of the band at any intermediate point of its arc of contact with the pulley; θ the ratio of the length of that arc to the radius of the pulley; $d\theta$ the ratio of an indefinitely small element of that arc to the radius; $F=T_1-T_2$ the total friction between the band and the pulley; dF the elementary portion of that friction due to the elementary arc $d\theta$; f the coefficient of friction between the materials of the band and pulley.

Then, according to a principle proved in the articles STATICS and ARCH, it is known that the normal pressure at the elementary arc $d\theta$ is $Td\theta$, T being the mean tension of the band at that elementary arc; consequently the friction on that arc is $dF=fTd\theta$. Now that friction is also the difference between the tensions of the band at the two ends of the elementary arc, or $dT=dF=fTd\theta$; which equation being integrated throughout the entire arc of contact, gives the following formulæ:—

$$\left.\begin{aligned}&\text{hyp. log}\ \frac{T_1}{T_2}=f\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad .\\ &\frac{T_1}{T_2}=e^{f\theta} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad .\\ &F=T_1-T_2=T_1\left(1-e^{-f\theta}\right)=T_2\left(e^{f\theta}-1\right)\end{aligned}\right\}(78.)$$

When a belt connecting a pair of pulleys has the tensions of its two sides originally equal, the pulleys being at rest; and when the pulleys are next set in motion, so that one of them drives the other by means of the belt; it is found that the advancing side of the belt is exactly as much tightened as the returning side is slackened; so that the *mean* tension remains unchanged. Its value is given by this formula—

$$\frac{T_1+T_2}{2}=\frac{e^{f\theta}+1}{2\left(e^{f\theta}-1\right)}, \quad . \quad . \quad . \quad (79.)$$

which is useful in determining the original tension required to enable a belt to transmit a given force between two pulleys.

The equations 78 and 79 are applicable to a kind of *brake* called a *friction-strap*, used to stop or moderate the velocity of machines by being tightened round a pulley. The strap is usually of iron, and the pulley of hard wood.

Let a denote the arc of contact expressed in *turns and fractions of a turn*; then

$$\left.\begin{aligned}&\theta=6{\cdot}2832a\\ &e^{f\theta}=\text{number whose common logarithm is } 2{\cdot}7288fa\end{aligned}\right\}(80.)$$

119. *Stiffness of Ropes.*—Ropes offer a resistance to being bent, and when bent, to being straightened again, which arises from the mutual friction of their fibres. It increases with the sectional area of the rope, and is inversely proportional to the radius of the curve into which it is bent.

The *work lost* in pulling a given length of rope over a pulley is found by multiplying the length of the rope in feet by its stiffness in pounds; that stiffness being the excess of the tension at the leading side of the rope above that at the following side, which is necessary to bend it into a curve fitting the pulley, and then to straighten it again.

The following empirical formulæ for the stiffness of hempen ropes have been deduced by Morin from the experiments of Coulomb:—

Let F be the stiffness in pounds avoirdupois; d the diameter of the rope in inches, $n=48d^2$ for white ropes, $35d^2$ for tarred ropes; r the *effective* radius of the pulley in inches; T the tension in pounds. Then

$$\left.\begin{aligned}\text{For white ropes, } \mathrm{F} &= \frac{n}{r}(0\cdot0012 + 0\cdot001026n + 0\cdot0012\mathrm{T})\\ \text{For tarred ropes, } \mathrm{F} &= \frac{n}{r}(0\cdot006 + 0\cdot001392n + 0\cdot00168\mathrm{T})\end{aligned}\right\} \quad (81.)$$

120. *Friction-Couplings.*—Friction is useful as a means of communicating motion where sudden changes either of force or velocity take place; because, being limited in amount, it may be so adjusted as to limit the forces which strain the pieces of the mechanism within the bounds of safety. Amongst contrivances for effecting this object are *friction-cones.* A rotating shaft carries upon a cylindrical portion of its figure a wheel or pulley turning loosely on it, and consequently capable of remaining at rest when the shaft is in motion. This pulley has fixed to one side, and concentric with it, a short frustum of a hollow cone. At a small distance from the pulley the shaft carries a short frustum of a solid cone accurately turned to fit the hollow cone. This frustum is made always to turn along with the shaft by being fitted on a square portion of it, or by means of a rib and groove, or otherwise; but is capable of a slight longitudinal motion, so as so be pressed into, or withdrawn from, the hollow cone by means of a lever. When the cones are pressed together or engaged, their friction causes the pulley to rotate along with the shaft; when they are disengaged, the pulley is free to stand still. The angle made by the sides of the cones with the axis should not be less than the angle of repose. In the *friction-clutch,* a pulley loose on a shaft has a hoop or gland made to embrace it more or less tightly by means of a screw: this hoop has short projecting arms or ears. A fork or *clutch* rotates along with the shaft, and is capable of being moved longitudinally by a handle. When the clutch is moved towards the hoop, its arms catch those of the hoop, and cause the hoop to rotate and to communicate its rotation to the pulley by friction. There are many other contrivances of the same class, but the two just mentioned may serve for examples.

121. *Heat of Friction—Unguents.*—The work lost in friction is employed in producing heat. This fact is very obvious, and has been known from a remote period; but the *exact* determination of the proportion of the work lost to the beat produced, and the experimental proof that that proportion is the same under all circumstances, and with all materials, solid, liquid, and gaseous, are recent achievements of Mr Joule. The quantity of work which produces a British unit of heat (or so much heat as elevates the temperature of one pound of pure water, at or near ordinary atmospheric temperatures, by one degree of Fahrenheit) is 772 foot-pounds. This constant, now designated as "Joule's Equivalent," is the principal experimental datum of the science of THERMODYNAMICS, which treats of the relations between heat and mechanical work.

The heat produced by friction, when moderate in amount, is useful in softening and liquifying thick unguents; but when excessive it is prejudicial, by decomposing the unguents, and sometimes even by softening the metal of the bearings, and raising their temperature so high as to set fire to neighbouring combustible matters.

Excessive heating is prevented by a constant and copious supply of a good unguent. The elevation of temperature produced by the friction of a journal is sometimes used as an experimental test of the quality of unguents. When the velocity of rubbing is about 4 or 5 feet per second, the elevation of temperature has been found by some recent experiments to be, with good fatty and soapy unguents, 40° to 50° Fahrenheit; with good mineral unguents, about 30°.

122. *Rolling Resistance.*—By the rolling of two surfaces over each other without sliding, a resistance is caused which is called sometimes "rolling friction," but more correctly *rolling resistance.* It is of the nature of a *couple,* resisting rotation. Its *moment* is found by multiplying the normal pressure between the rolling surfaces by an *arm,* whose length depends on the nature of the rolling surfaces, and the work lost in a unit of time in overcoming it is the product of its moment by the *angular velocity* of the rolling surfaces relatively to each other. The following are approximate values of the arm in *decimals of a foot*:—

Oak upon oak..................	0·006	(Coulomb.)
Lignum vitæ on oak...........	0·004	(Do)
Cast-iron on cast-iron........	0·002	(Tredgold.)

123. *Reciprocating Forces—Stored and Restored Energy.*—When a force acts on a machine alternately as an effort and as a resistance, it may be called a *reciprocating force.* Of this kind is the weight of any piece in the mechanism whose centre of gravity alternately rises and falls; for during the rise of the centre of gravity that weight acts as a resistance, and energy is employed in lifting it to an amount expressed by the product of the weight into the vertical height of its rise; and during the fall of the centre of gravity the weight acts as an effort, and exerts in assisting to perform the work of the machine an amount of energy exactly equal to that which had previously been employed in lifting it. Thus that amount of energy is not lost, but has its operation deferred; and it is said to be *stored* when the weight is lifted, and *restored* when it falls.

In a machine of which each piece is to move with an uniform velocity, if the effort and the resistance be constant, the weight of each piece must be balanced on its axis, so that it may produce lateral pressure only, and not act as a reciprocating force. But if the effort and the resistance be alternately in excess, the uniformity of speed may still be preserved by so adjusting some moving weight in the mechanism, that when the effort is in excess it may be lifted, and so balance and employ the excess of effort; and that when the resistance is in excess it may fall, and so balance and overcome the excess of resistance; thus *storing* the periodical excess of energy, and *restoring* that energy to perform the periodical excess of work.

Other forces besides gravity may be used as reciprocating forces for storing and restoring energy; for example, the elasticity of a spring or of a mass of air.

In most of the delusive machines commonly called "perpetual motions," of which so many are patented in each year, and which are expected by their inventors to perform work without receiving energy, the fundamental fallacy consists in an expectation that some reciprocating force shall restore more energy than it has been the means of storing.

DIVISION II.—DEFLECTING FORCES.

124. *Deflecting Force for Translation in a Curved Path.*—If a body have a motion of translation with the velocity v, so that each point in it moves in a curved path of the radius ρ, then, as we have already seen (sect. 27.) the rate of deflection of that body's motion in unity of time, which is common to all its points, is expressed by

$\frac{v^2}{\rho} = \rho\alpha^2$, if α be substituted for $\frac{d\theta}{dt}$, the expression in equation 3 for the angular velocity of deflection.

To produce this deviation the body must (according to sect. 96, equation 60) be acted upon by a lateral pressure at right angles to, and towards the centre of curvature of its path, whose magnitude is given by the equation—

$$F = \frac{wv^2}{g\rho} = \frac{w\rho\alpha^2}{g}, \quad . \quad . \quad . \quad . \quad (82.)$$

where w is the weight of the body, and g the deviation produced by gravity in a second (see sect. 96); and as this total deflecting force F is the resultant of deflecting forces acting upon each particle of the body and proportional respectively to the masses of the particles, its line of action must traverse the centre of gravity of the body.

In machinery, deflecting force is supplied by the tenacity of some piece, such as a crank, which guides the deflected body in its curved path, and is *unbalanced*, being employed in producing deflection, and not in balancing another force.

125. *Centrifugal Force.*—The deflecting body reacts upon the guiding body with a lateral pressure equal and opposite to the deflecting force, and called the *centrifugal force*, because of its arising from the tendency of the deflected body to move in a straight line, and so to fly from the centre of its curved path; and also because of its tending to pull the guiding body away from that centre.

In fact, as has been stated in section 95, every force is a pair of equal and opposite actions between a pair of bodies; and *deflecting force* and *centrifugal force* are but two different names for the same force, applied to it according as its action on the deflected body or on the guiding body is under consideration for the time. The action on the deflected body is to produce deflection at a rate proportional to the force; the action on the guiding body is to strain it and the framework which carries it, to be balanced by the stiffness which resists that strain, and to cause increased friction at rubbing surfaces. Hence it appears that the action of centrifugal force is in general prejudicial, and that it is desirable in well-designed machinery to diminish it as much as possible.

126. *Rectangular Resolution of Centrifugal Force.*—For convenience in mathematical investigation, centrifugal force may be resolved into rectangular components as follows:—In fig. 35 let O be the centre of curvature and ρ the radius of the path of the centre of gravity of the body w, whose angular velocity of deflection is α. Let OX, OY be a pair of rectangular axes in the plane of motion of w, and x, y perpendiculars let fall from the centre of gravity of w upon these axes. It is evident that the centrifugal force exerted by w upon an axis at O may be resolved into two rectangular components, F_x, F_y, parallel to OX, OY respectively, and bearing to each other and to the whole centrifugal force F the following proportions:—

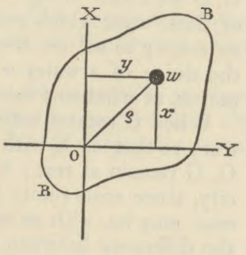

Fig. 35.

$$\left.\begin{array}{l} F : F_x : F_y \\ \quad :: \rho : x : y; \\ \text{consequently their values are—} \\ F_x = \dfrac{wx\alpha^2}{g};\ F_y = \dfrac{wy\alpha^2}{g}. \end{array}\right\} \quad . \quad . \quad . \quad (83.)$$

127. *Centrifugal Force of a Rotating Body.*—Let a body of any figure BB rotate about the axis of rotation O, perpendicular to the plane XOY of the rectangular axes of co-ordinates before-mentioned. Let W be the entire weight of the body; let α be its angular velocity of rotation; this, as shown in section 38, is also the angular velocity of deflection of each particle of the body in its revolution round the axis. Conceive the body to be divided into an indefinite number of indefinitely small particles; denote one of them by dW, and let its co-ordinates be x and y. The components of the centrifugal force exerted by it on the axis O are respectively

$$\frac{x\alpha^2 dW}{g} \text{ and } \frac{y\alpha^2 dW}{g};$$

and the components of the centrifugul force exerted by the *whole body* on that axis, being the sums or integrals of the centrifugal forces exerted by all the particles, are expressed by—

$$F_x = \frac{\alpha^2}{g}\int x \cdot dW, \text{ and } F_y = \frac{\alpha^2}{g}\int y \,.\, dW.$$

Now, by the properties of the centre of gravity (for which see STATICS), if x_1 and y_1 be the co-ordinates of the centre of gravity of the body BB,

$$\int x \cdot dW = x_1 W;\ \int y \cdot dW = y_1 W;$$

consequently

$$F_x = \frac{Wx_1\alpha^2}{g};\ F_y = \frac{Wy_1\alpha^2}{g}; \quad . \quad . \quad (84.)$$

being precisely the same values which were found in section 126, equation 83, for the components of the centrifugal force due to a circular translation with a radius equal to the distance of the centre of gravity of the body from the axis of rotation.

Hence *the centrifugal force exerted by a rotating body on its axis of rotation, is the same in magnitude as if the mass of the body were concentrated at its centre of gravity, and acts in a plane passing through the axis of rotation and the centre of gravity of the body.*

The particles of a rotating body exert centrifugal forces on each other, which strain the body, and tend to tear it asunder; but these forces balance each other, and do not affect the resultant centrifugal force exerted on the axis of rotation.[1]

If the axis of rotation traverses the centre of gravity of the body, the centrifugal force exerted on that axis is nothing.

Hence, unless there be some reason to the contrary, each piece of a machine should be balanced on its axis of rotation; otherwise the centrifugal force will cause strains, vibration, and increased friction, and a tendency of the shafts to jump out of their bearings.

128. *Centrifugal Couples of a Rotating Body.*—Besides the tendency (if any) of the combined centrifugal forces of the particles of a rotating body to *shift* the axis of rotation, they may also tend to *turn* it out of its original direction. The latter tendency is called a *centrifugal couple.*

To determine its amount, or the amount of its components, let z denote the distance (positive towards, negative from, the spectator), of any given particle dW from the plane XOY. Then the tendencies of the centrifugal force of dW to turn the axis of rotation O towards the right hand, about OX, is the moment of the couple, $-\dfrac{zy\alpha^2 dW}{g}$, and about OY, the moment of the couple, $+\dfrac{zx\alpha^2 dW}{g}$; and by integrating those expressions, the centrifugal couples of the whole body are found to be respectively—

---

[1] This is a particular case of a more general principle, that *the motion of the centre of gravity of a body is not affected by the mutual actions of its parts*; for the proof of which see DYNAMICS.

$$M_x = -\frac{a^2}{g} \cdot \int zy \cdot dW, \qquad M_y = -\frac{a^2}{g} \cdot \int zx \cdot dW. \qquad \ldots (85.)$$

A *permanent* or *principal axis* of rotation is one for which each of the centrifugal couples, as well as the centrifugal force, is nothing, and is the only kind of axis about which a body not acted upon by an external force can steadily rotate. It can be proved that every body, of what shape soever, has *at least* three permanent axes at right angles to each other.

It is essential to the steady motion of every rapidly rotating piece in a machine, that its axis of rotation should not merely traverse its centre of gravity, but should be a permanent axis; for otherwise the centrifugal couples will increase friction, produce oscillation of the shaft, and tend to make it leave its bearings.

The principles of this and the preceding section are those which regulate the adjustment of the weight and position of the *counterpoises* which are placed between the spokes of the driving-wheels of locomotive engines.

129. *Revolving Pendulum—Governors.*—In fig. 36 AO represents an upright axis or spindle; B a weight called a *bob*, suspended by a rod OB from a horizontal axis at O, carried by the vertical axis. When the spindle is at rest the bob hangs close to it; when the spindle rotates, the bob, being made to revolve round it, diverges until the resultant of the centrifugal force and the weight of the bob is a force acting at O in the direction OB, and then it revolves steadily in a circle. This combination is called a *revolving*, *centrifugal*, or *conical pendulum.* Revolving pendulums are usually constructed with *pairs* of rods and bobs, as OB, O*b*, hung at opposite sides of the spindle, that the centrifugal forces exerted at the point O may balance each other.

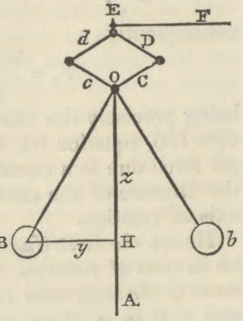

Fig. 36.

In finding the position in which the bob will revolve with a given angular velocity a, for most practical purposes connected with machinery the mass of the rod may be considered as insensible compared with that of the bob. Let the bob be a sphere, and from the centre of that sphere draw $BH = y$ perpendicular to OA. Let $OH = z$; let W be the weight of the bob, F its centrifugal force. Then the condition of its steady revolution is $W : F :: z : y$; that is to say, $\frac{y}{z} = \frac{F}{W} = \frac{ya^2}{g}$; consequently,

$$z = \frac{g}{a^2} \quad \ldots \ldots (86.)$$

Or, if $n = \frac{a}{2\pi} = \frac{a}{6{\cdot}2832}$ be the number of turns or fractions of a turn in a second,

$$z = \frac{g}{4\pi^2 n^2} = \frac{0{\cdot}8165 \text{ foot}}{n^2} = \frac{9{\cdot}79771 \text{ inches}}{n^2} \quad (87.)$$

z is called the *altitude of the pendulum.*

If the rod of a revolving pendulum be jointed, as in fig. 37, not to a point in the vertical axis, but to the end of a projecting arm C, the position in which the bob will revolve will be the same as if the rod were jointed to the point O, where its prolongation cuts the vertical axis.

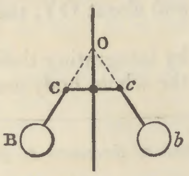

Fig. 37.

A revolving pendulum is an essential part of most of the contrivances called *governors,* for regulating the speed of prime movers.

The earlier kinds of governors act on the prime mover by the variations of their altitude. Thus, in Watt's steam-engine governor the rods, through a combination of levers and linkwork C*c*, D*d* (fig. 36), act on a lever EF, which acts upon the throttle-valve for the admission of steam so as to enlarge its opening when the speed becomes too small, and contract it when the speed becomes too great.

In a more recent kind of governors invented by the Messrs Siemens, which may be called *differential governors,* the regulation of the prime mover is effected by means of the difference between the velocity of a wheel driven by it and that of a wheel regulated by a revolving pendulum. Fig. 38 illustrates this class of governors: A is a vertical dead-centre or fixed shaft, about which the after-mentioned pieces turn; C is a pulley driven by the prime mover, and fixed to a bevel-wheel, which is seen below it; E is a bevel-wheel similar to the first, and having the same apex. To this wheel are hung the bobs B, of which there are usually four, although two only are shown. Those bobs form sectors of a ring, and are surrounded by a cylindrical casing F. When the bobs revolve with their proper velocity, they are adjusted so as nearly to touch this casing; should they exceed that velocity, they fly outwards and touch the casing, and are retarded by the friction. For practical purposes their velocity of rotation about the vertical axis may be considered constant. G, G are horizontal arms projecting from a socket, which is capable of rotation about A, and carrying vertical bevel wheels which rest on E and support C, and transmit motion from C to E. There are usually four of the arms G, G with their wheels, though two only are shown. H is one of those arms which projects, and has a rod attached to its extremity to act on the throttle-valve of a steam-engine, the sluice of a water-wheel, or the regulator of the prime mover, of what sort soever it may be.

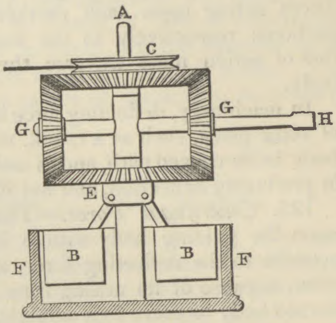

Fig. 38.

When C rotates with an angular velocity equal and contrary to that of E with its revolving pendulums, the arms G, G remain at rest; but should C deviate from that velocity, those arms rotate in one direction or the other, as the case may be, with an angular velocity equal to one-half of the difference between the angular velocity of C and that of E, and continue in motion until the regulator is adjusted so that the prime mover shall impart to C an angular velocity exactly equal to that of the revolving pendulums.

There are various modifications of the differential governor, but they all act on the same principle.

DIVISION III.—WORKING OF MACHINES OF VARYING VELOCITY.

130. *General Principles.*—In order that the velocity of every piece of a machine may be uniform, it is necessary that the forces acting on each piece should be always exactly balanced. Also, in order that the forces acting on each piece of a machine may be always exactly balanced, it is necessary that the velocity of that piece should be uniform.

An excess of the effort exerted on any piece, above that which is necessary to balance the resistance, is accompanied with acceleration; a deficiency of the effort, with retardation.

When a machine is being started from a state of rest, and brought by degrees up to its proper speed, the effort must be in excess; when it is being retarded for the purpose of stopping it, the resistance must be in excess.

An excess of effort above resistance involves an excess of energy exerted above work performed; that excess of energy is employed in producing acceleration.

An excess of resistance above effort involves an excess of work performed above energy expended; that excess of work is performed by means of the retardation of the machinery.

When a machine undergoes alternate acceleration and retardation, so that at certain instants of time, occurring at the end of intervals called *periods* or *cycles*, it returns to its original speed, then in each of those periods or cycles the alternate excesses of energy and of work neutralize each other; and at the end of each cycle the principle of the equality of energy and work stated in sect. 105, with all its consequences, is verified exactly as in the case of machines of uniform speed.

At intermediate instants, however, other principles have also to be taken into account, which are deduced from the second law of motion, sect. 95, as applied by the aid of the principles of sect. 96, to *direct deviation*, or acceleration and retardation.

131. *Energy of Acceleration and Work of Retardation for a Shifting Body.*—Let w be the weight of a body which has a motion of translation in any path, and in the course of the interval of time Δt let its velocity be increased at an uniform rate of acceleration from v_1 to v_2. The rate of acceleration will be

$$\frac{dv}{dt}=\text{constant}=\frac{v_2-v_1}{\Delta t};$$

and, according to sect. 96, equation 60, to produce this acceleration a uniform effort will be required, expressed by

$$\mathrm{P}=\frac{w\cdot(v_2-v_1)}{g\Delta t}. \quad . \quad . \quad . \quad (88.)$$

(The product $\frac{wv}{g}$ of the mass of a body by its velocity is called its *momentum;* so that the effort required is found by dividing the increase of momentum by the time in which it is produced.)

To find the *energy* which has to be exerted to produce the acceleration from v_1 to v_2, it is to be observed that the *distance* through which the effort P acts during the acceleration is

$$\Delta s=\frac{v+v}{2}\Delta t;$$

consequently, the *energy of acceleration* is

$$\mathrm{P}\Delta s=\frac{w(v_2-v_1)\,(v_2+v_1)}{2g}=\frac{w(v_2{}^2-v_1{}^2)}{2g}, \quad . \quad (89.)$$

being proportional to the increase in the square of the velocity, and *independent of the time.*

In order to produce a *retardation* from the greater velocity v to the less velocity v_1, it is necessary to apply to the body a *resistance*, connected with the retardation and the time by an equation identical in every respect with equation 88, except by the substitution of a resistance for an effort; and in overcoming that resistance the body *performs work* to an amount determined by equation 89, putting Rds for Pds.

132. *Energy Stored and Restored by Deviations of Velocity.*—Thus a body alternately accelerated and retarded, so as to be brought back to its original speed, performs work during its retardation exactly equal in amount to the energy exerted upon it during its acceleration; so that that energy may be considered as *stored* during the acceleration, and *restored* during the retardation, in a manner analogous to the operation of a reciprocating force (sect. 123).

Let there be given the mean velocity $\mathrm{V}=\frac{v_2+v_1}{2}$ of a body whose weight is w, and let it be required to determine the fluctuation of velocity v_2-v_1, and the extreme velocities v_1, v_2, which that body must have, in order alternately to store and restore an amount of energy E. By equation 30 we have

$$\mathrm{E}=\frac{w(v_2{}^2-v_1{}^2)}{2g},$$

which, being divided by $\mathrm{V}=\frac{v_1+v_2)}{2}$, gives

$$\frac{\mathrm{E}}{\mathrm{V}}=\frac{w(v_2-v_1)}{g};$$

and consequently

$$v_2-v_1=\frac{g\mathrm{E}}{\mathrm{V}w} \quad . \quad . \quad . \quad . \quad . \quad (90.)$$

The ratio of this fluctuation to the mean velocity, sometimes called the *unsteadiness* of the motion of the body, is

$$\frac{v_2-v_1}{\mathrm{V}}=\frac{g\mathrm{E}}{\mathrm{V}^2w}. \quad . \quad . \quad . \quad . \quad . \quad (91.)$$

133. *Actual Energy of a Shifting Body.*—The energy which must be exerted on a body of the weight w, to accelerate it from a state of rest up to a given velocity of translation v, and the equal amount of work which that body is capable of performing by overcoming resistance while being retarded from the same velocity of translation v to a state of rest, is

$$\frac{wv^2}{2g}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (92.)$$

This is called the *actual energy* of the motion of the body, and is one-half of the quantity which is called *vis-viva* in some treatises on mechanics.

The energy stored or restored, as the case may be, by the deviations of velocity of a body, or a system of bodies, is the amount by which the actual energy is increased or diminished, as the case may be.

134. *Principle of the Conservation of Energy in Machines.*—The following principle, expressing the general law of the action of machines with a velocity uniform or varying, includes the law of the equality of energy and work stated in sect. 105 for machines of uniform speed.

In any given interval during the working of a machine, the energy exerted added to the energy restored is equal to the energy stored added to the work performed.

135. *Actual Energy of Circular Translation—Moment of Inertia.*—Let a body of the weight w undergo translation in a circular path of the radius ρ, with the angular velocity of deflection α, so that the common linear velocity of all its particles is $v=\alpha\rho$. Then the actual energy of that body is

$$\frac{wv^2}{2g}=\frac{w\alpha^2\rho^2}{2g}. \quad . \quad . \quad . \quad . \quad . \quad (93.)$$

By comparing this with equation 82, sect. 124, it appears that the actual energy of a revolving body is equal to the potential energy $\frac{\mathrm{F}\rho}{2}$ due to the action of the deflecting force along one-half of the radius of curvature of the path of the body.

The product $\frac{w\rho^2}{g}$ by which the half-square of the angular-velocity is multiplied, is called the *moment of inertia* of the revolving body.

136. *Actual Energy and Moment of Inertia of Rotation —Radius of Gyration.*—Let a body of any figure BB (see fig. 35, sect. 126) rotate about the axis of rotation O, perpendicular to the plane XOY; let w be the entire weight of the body; let α be its angular velocity of rotation, being also the angular velocity of deflection of each of its particles in its revolution round the axis. Conceive the body to be divided into an indefinite number of indefinitely small particles; denote the weight of one of them by dW; and let its perpendicular distance from the axis be ρ. The actual energy of that particle, according to sect. 135, is

$$\frac{\alpha^2\rho^2\cdot dW}{2g};$$

and the actual energy of the whole body, being the sum or integral of the actual energies of its particles, is

$$\frac{\alpha^2}{2g}\int\rho^2\cdot dW. \quad . \quad . \quad . \quad (94.)$$

The integral in this expression, by which the half-square of the angular velocity is multiplied, viz.,—

$$\frac{1}{g}\int\rho^2\cdot dW = I, \quad . \quad . \quad . \quad (95.)$$

is the *moment of inertia* of the whole body relatively to the given axis O, being the sum of the moments of inertia of all its particles. The actual energy of the body may be thus expressed:

$$\frac{I\alpha^2}{2} \quad . \quad . \quad . \quad . \quad . \quad (96.)$$

If the moment of inertia be divided by the mass $\frac{W}{g}$ of the body, the result is

$$R^2 = \frac{gI}{W}, \quad . \quad . \quad . \quad . \quad (97.)$$

the square of a length called the *radius of gyration;* being the distance from the axis O at which, if the whole mass of the body were collected at one or more points, or in a ring, or hollow cylinder, the moment of inertia would be the same with that of the actual body.

If the given axis O do not already traverse the centre of gravity of the body, conceive an axis parallel to it to be drawn through that centre of gravity, and designated by the symbol G. Let $\rho_1 = \overline{OG}$ be the perpendicular distance between those axis. Let R_0 be the radius of gyration, and $I_0 = \frac{R_0^2W}{g}$, the moment of inertia of the body about the axis G. Then, from geometrical properties of the centre of gravity, the proof of which belongs to the subject of statics, it is known that

$$R^2 = R_0^2 + \rho_1^2; \quad . \quad . \quad . \quad . \quad (98.)$$

from which it follows that

$$I = I_0 \times \frac{\rho_1^2W}{g}; \quad . \quad . \quad . \quad . \quad (99.)$$

that is to say, *the moment of inertia of a body about any axis* O, *not traversing its centre of gravity, is equal to the moment of inertia of the whole body about an axis* G, *traversing the centre of gravity parallel to* O, *added to the moment of inertia due to a circular translation of the whole body with the radius* $\overline{OG}$.[1]

From equation 99 it follows obviously, that the moment of inertia of a body about an axis traversing its centre of gravity in a given direction, is less than about any other axis parallel to that direction.

The respective moments of inertia of a body about its permanent axes of rotation (sect. 128), are called its *principal moments of inertia.*

137. *Examples of Radii of Gyration.*—The following are some examples, useful in practice, of the radii of gyration of homogeneous solids about permanent axes:—

I. A sphere of the radius r rotating about a diameter, ... $R_0^2 = \frac{2r^2}{5}$

II. A spheroid of revolution rotating about its polar axis, its equatorial radius being r, $R_0^{2'} = \frac{2r^2}{5}$

III. An ellipsoid whose semi-axes are a, b, c, rotating about the axis $2a$, ... $R_0^2 = \frac{b^2+c^2}{5}$

IV. A cylindrical disc of the radius r, rotating about its axis of figure, ... $R_0^2 = \frac{r^2}{2}$

V. A cylindrical ring, or hollow cylinder, rotating about its axis of figure, the external and internal radii being r, r^1, ... $R_0^2 = \frac{r^2+r^{12}}{2}$
(This is applicable to many cases of rims of fly-wheels.)

VI. A rectangular parallelopiped whose dimensions are $2a$, $2b$, $2c$, rotating about the axis whose length is $2a$, ... $R_0^2 = \frac{b^2+c^2}{3}$

VII. A slender rod of uniform section and length $2l$, rotating about an axis crossing it at right angles in the middle of its length, $R_0^2 = \frac{l^2}{3}$
(This case is also applicable to any system of rods of equal length l, radiating from a common axis, like the spokes of a fly-wheel.)

VIII. A system of bodies of respective weights w, w', w'', &c., rotating about a common axis, and having the respective radii of gyration ρ, ρ', ρ'', &c., ... $R_0^2 = \frac{\Sigma\cdot w\rho}{\Sigma\cdot w}$

138. *Fly-Wheels.*—A fly-wheel is a rotating piece in a machine, generally shaped liked a wheel (that is to say, consisting of a rim with spokes), and suited to store and restore energy by the periodical variations in its angular velocity.

The principles according to which variations of angular velocity store and restore energy are the same with those of sect. 132, only substituting *moment of inertia* for *mass*, and *angular* for *linear* velocity.

Let W be the weight of a fly-wheel, R its radius of gyration, α_2 its maximum, α_1 its minimum, and $A = \frac{\alpha_2+\alpha_1}{2}$ its mean angular velocity. Let

$$\frac{1}{S} = \frac{\alpha_2 - \alpha_1}{A}$$

denote the *unsteadiness* of the motion of the fly-wheel; the denominator S of this fraction is called the *steadiness.* Let e denote the quantity by which the energy exerted in each cycle of the working of the machine alternately exceeds and falls short of the work performed, and which has consequently to be alternately stored by acceleration, and restored by retardation of the fly-wheel. The value of this *periodical excess* is—

---

[1] This is a particular case of a more general proposition, that *the whole actual energy of any system of masses is equal to the actual energy due to a motion of the whole of those masses with the velocity of their common centre of gravity, added to the sum of the actual energies due to the several motions of the several masses relatively to that common centre of gravity.*

$$e=\frac{R^2W(a_2{}^2-a_1{}^2)}{2g}; \quad . \quad . \quad . \quad (100.)$$

from which, dividing both sides by A^2, we obtain the following equations:—

$$\left.\begin{array}{l}\frac{e}{}=\frac{R^2W}{gS};\\ \frac{R^2WA^2}{2g}=\frac{Se}{2}.\end{array}\right\} \quad . \quad . \quad . \quad (101.)$$

The latter of these equations may be thus expressed in words:—*The actual energy due to the rotation of the fly, with its mean angular velocity, is equal to one-half of the periodical excess of energy multiplied by the steadiness.*

In ordinary machinery, S = about 32; in machinery for fine purposes S = from 50 to 60.

The periodical excess e may arise either from variations in the effort exerted by the prime mover, or from variations in the resistance of the work, or from both these causes combined. When but one fly-wheel is used, it should be placed in as direct connection as possible with that part of the mechanism where the greatest amount of the periodical excess originates; but when it originates at two or more points, it is best to have a fly-wheel in connection with each of those points. For example, in a machine-work, the steam-engine, which is the prime mover of the various tools, has a fly-wheel on the crank-shaft to store and restore the periodical excess of energy arising from the variations in the effort exerted by the connecting-rod upon the crank; and each of the slotting machines, punching machines, rivetting-machines, and other tools, has a fly-wheel of its own to store and restore energy, so as to enable the very different resistances opposed to those tools at different times to be overcome without too great unsteadiness of motion.

According to the computation of General Morin, the periodical excess e in steam-engines with single cranks is from $\frac{1}{10}$th to nearly $\frac{1}{4}$th of the energy exerted during one revolution of the crank. For a pair of steam-engines driving one shaft, with a pair of cranks at right angles to each other, the value of e is one-fourth of its value for a single cranked engine of the same kind, and of the same power with the two combined.

The ordinary radius of gyration of a steam-engine fly-wheel is from three to five times the length of the crank-arm. (For further particulars on this subject, see STEAM-ENGINE.)

For tools performing useful work at intervals, and having only their own friction to overcome during the intermediate intervals, e should be assumed equal to the whole work performed at each separate operation.

139. *Brakes.*—A brake is an apparatus for stopping or diminishing the velocity of a machine by friction, such as the friction-strap already referred to in sect. 118. To find the distance s through which a brake, exerting the friction F, must rub in order to stop a machine having the total actual energy E at the moment when the brake begins to act, reduce, by the principles of sect. 111, the various efforts and other resistances of the machine which act at the same time with the friction of the brake to the rubbing surface of the brake, and let R be their resultant,—*positive* if resistance, *negative* if effort preponderates. Then

$$s=\frac{E}{F+R} \quad . \quad . \quad . \quad . \quad (102.)$$

140. *Energy distributed between two Bodies—Projection and Propulsion.*—Hitherto the effort by which a machine is moved has been treated as a force exerted between a moveable body and a fixed body, so that the whole energy exerted by it is employed upon the moveable body, and none upon the fixed body. This conception is sensibly realized in practice when one of the two bodies between which the effort acts is either so heavy as compared with the other, or has so great a resistance opposed to its motion, that it may, without sensible error, be treated as fixed. But there are cases in which the motions of both bodies are appreciable, and must be taken into account; such as the projection of projectiles, where the velocity of the *recoil* or backward motion of the gun bears an appreciable proportion to the forward motion of the projectile; and such as the propulsion of vessels, where the velocity of the water thrown backward by the paddle, screw, or other propeller, bears a very considerable proportion to the velocity of the water moved forwards and sideways by the ship. In cases of this kind the energy exerted by the effort is *distributed* between the two bodies between which the effort is exerted, in shares proportional to the velocities of the two bodies during the action of the effort; and those velocities are to each other, directly as the portions of the effort unbalanced by resistance on the respective bodies, and inversely as the weights of the bodies.

To express this symbolically, let W_1, W_2 be the weights of the bodies; P the effort exerted between them; S the distance through which it acts; R_1, R_2 the resistances opposed to the effort overcome by W_1, W_2 respectively; E_1, E_2 the shares of the whole energy E exerted upon W_1, W_2 respectively. Then

$$\left.\begin{array}{ccccc} E & : & E_1 & : & E_2 \\ ::\frac{W_2(P-R_1)+W_1(P-R_2)}{W_1W_2} & : & \frac{P-R_1}{W_1} & : & \frac{P-R_2}{W_2}\end{array}\right\} (103.)$$

If $R_1=R_2$, which is the case when the resistance, as well as the effort, arises from the mutual actions of the two bodies, the above becomes,

$$\left.\begin{array}{ccccc} E & : & E_1 & : & E_2 \\ ::W_1+W_2 & : & W_2 & : & W_1\end{array}\right\}; \quad . \quad . \quad (104.)$$

that is to say, the energy is exerted on the bodies in shares inversely proportional to their weights; and they receive accelerations inversely proportional to their weights, according to the principle of dynamics, already quoted in a note to sect. 127, that the mutual actions of a system of bodies do not affect the motion of their common centre of gravity.

For example, if the weight of a gun be 160 times that of its ball, $\frac{160}{161}$ of the energy exerted by the powder in exploding will be employed in propelling the ball, and $\frac{1}{161}$ in producing the recoil of the gun; provided the gun, up to the instant of the ball's quitting the muzzle, meets with no resistance to its recoil except the friction of the ball.

141. *Centre of Percussion.*—In order that a rigid solid body may have a given deviation imparted to it, it is sufficient that the *resultant* of the unbalanced force or forces applied to it should be identical in magnitude, direction, and position, with the *resultant* of the forces, which, if applied separately to the several particles of the body, would give each of them the deviation which it is required to have as forming a part of the body.[1] The nearest point in the line of action of this resultant to the centre of gravity of the body is called the *centre of percussion* of the body for the given kind of deviation. It indicates the position and direction in which a *single* force must act in order to produce deviation in the required manner. (Details respecting the centre of percussion will be found in the article DYNAMICS.)

It is obviously desirable that the deviations or changes of motion of oscillating pieces in machinery should, as far as possible, be effected by forces applied at their centres of percussion.

If the deviation be a *translation*,—that is an equal change of motion of all the particles of the body,—the centre of percussion is obviously the centre of gravity itself; and, as already stated (sect. 96, equation 60), if dv be the deviation of velocity to be produced in the interval dt, and W the weight of the body,—

---

[1] This is a particular case of the principle of Dynamics, known as "D'Alembert's principle."

$$P=\frac{W}{g}\cdot\frac{dv}{dt} \quad . \quad . \quad . \quad . \quad (105.)$$

is the unbalanced effort required.

If the deviation be a rotation about an axis traversing the centre of gravity, there is no centre of percussion; for such a deviation can only be produced by a *couple* of forces, and not by any single force. Let da be the deviation of angular velocity to be produced in the interval dt; I the moment of inertia of the body; then $\frac{1}{2}Id(a^2)=Iada$ is the variation of the body's actual energy. Let M be the moment of the unbalanced couple required to produce the deviation; then, by equation 70, sect. 110, the energy exerted by this couple in the interval dt is $Madt$, which, being equated to the variation of energy, gives

$$M=I\frac{da}{dt}=\frac{R_0^2W}{g}\cdot\frac{da}{dt} \quad . \quad . \quad . \quad . \quad (106.)$$

Now, let the required deviation be a rotation of the body BB about an axis O, not traversing the centre of gravity G, da being, as before, the deviation of angular velocity to be produced in the interval dt. According to the principle of sect. 44, a rotation with the angular velocity a about an axis O may be considered as compounded of a rotation with the same angular velocity about an axis drawn through G parallel to O, and a translation with the velocity $a\cdot\overline{OG}$; $\overline{OG}$ being the perpendicular distance between the two axes. Hence the required deviation may be regarded as compounded of a deviation of translation $dv=OG\cdot da$, to produce which there would be required, according to equation 105, a force applied at G perpendicular to the plane OG—

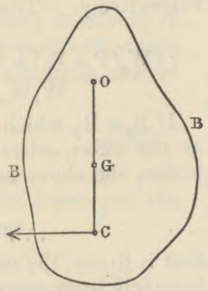

Fig. 39.

$$P=\frac{W}{g}\cdot\overline{OG}\cdot\frac{da}{dt}, \quad . \quad . \quad . \quad (107.)$$

and a deviation da of rotation about an axis drawn through G parallel to O, to produce which there would be required a couple of the moment M given by equation 106. According to the principles of statics, the resultant of the force P applied at G perpendicular to the plane OG, and of the couple M, is a force equal and parallel to P, but applied at a distance $\overline{GC}$ from G, in the prolongation of the perpendicular $\overline{OG}$, whose value is

$$\overline{GC}=\frac{M}{P}=\frac{R_0^2}{\overline{OG}}\cdot \quad . \quad . \quad . \quad (108.)$$

Thus is determined the position of the centre of percussion C, corresponding to the axis of rotation O. It is obvious from this equation that, for an axis of rotation parallel to O traversing C, the centre of percussion is at the point where the perpendicular $\overline{OG}$ meets O.

142. *Impact.*—Impact or collision is a pressure of short duration exerted between two bodies. (For the detailed investigation of its laws the reader is referred to DYNAMICS.)

The effects of impact are sometimes an alteration of the distribution of actual energy between the two bodies, and always a loss of a portion of that energy, depending on the imperfection of the elasticity of the bodies, in permanently altering their figures, and producing heat. The determination of the distribution of the actual energy after collision, and of the loss of energy, is effected by means of the following principles:—

I. The motion of the common centre of gravity of the two bodies is unchanged by the collision.

II. The loss of energy consists of a certain proportion of that part of the actual energy of the bodies which is due to their motion relatively to their common centre of gravity.

Unless there is some special reason for using impact in machines, it ought to be avoided, on account not only of the waste of energy which it causes, but of the damage which it occasions to the frame and mechanism.

CHAPTER III.—PURPOSES AND EFFECTS OF MACHINES.

143. *Observing Machines and Working Machines.*—The present chapter must necessarily be limited to some very general observations on the principal classes into which machines may be divided, with reference to their purposes and effects, leaving the reader to find, under special heads in this Encyclopædia, the detailed descriptions of particular examples.

Machines may be divided, in the first instance, into two great divisions, viz.:—

I. *Observing machines*, in which either the modification of motion alone, or the balancing of forces alone, is the object in view,—the performance of work being either null or incidental, and being limited to that which arises from the resistance of the machine.

II. *Working machines*, in which the performance of work is the main object.

144. *Classification of Observing Machines.*—Observing machines might very properly have been classed as *instruments*, being designed to aid the human senses and memory in obtaining and recording information. They may be divided, in the first instance, into four classes, according as the subject of observation by their aid is number, measure, or weight, into—

A: Counting machines.
B: Measuring machines.
C: Copying and drawing machines.
D: Weighing machines.

And to these may be added a fifth class, in which the functions of the first four are more or less combined, viz.,—

E: Recording machines.

145. *Counting Machines.*—The most important as well as the most common of counting machines are *time-keepers*, which count and indicate the numbers of oscillations of bodies which oscillate isochronously (viz., pendulums for clocks, balance-wheels for watches and marine chronometers) so as to measure time. In constructing such machines, the objects to be aimed at are the exact isochronism of the pendulum or balance, and the equable action of the motive power, so that it shall overcome the friction of the mechanism without affecting the rate. (See CHRONOMETER; CLOCK AND WATCH WORK; PENDULUM.)

Other counting machines count the oscillations of the beam of a steam-engine, the revolutions of the cylinder of a gas-meter, or of the wheel of a water-meter.

Others perform additions, subtractions, and multiplications, and of these the most elaborate kind (of which there are but two in existence,—the machine of Mr Babbage and that of Messrs Scheutz) compute tables of functions by the addition of differences.

146. *Measuring Machines.*—Measuring machines are pieces of mechanism, by means of which the motion of

some body of the nature of an index through some geometrical magnitude, such as a distance or an angle, is connected with some other motion, either equal or greater or smaller in some given ratio, and capable of being more readily compared with some standard of measure.

To this class belong all those astronomical and surveying instruments in which the motion of a line of sight (generally the line of collimation of a telescope) through a given angle is connected with the motion of an index or vernier round a corresponding arc of a graduated circle; also those micrometers in which the advance of the end of a screw of fine pitch is measured by observing the simultaneous arc of rotation of a graduated circle which is attached to it.

Such micrometers have attained increased importance by the discovery of Mr Whitworth,—that the mechanical magnifying of small distances by a train of screws affords a more accurate means of measurement than optical magnifying by the microscope,—and by the perfection to which that engineer has brought that art of accurate workmanship which is necessary in order to render mechanical magnifying possible.

Amongst measuring machines are included the *platometers* or *planimeters* of Mr Sang, General Morin, and Mr Clerk Maxwell, which measure areas by means of mechanism. The amount of resistance in a measuring-machine should be perfectly uniform, and sufficiently great to prevent accidental forces from disturbing the machine, without being so great as to render it inconveniently stiff. To combine these objects requires great accuracy of workmanship, together with strength and rigidity in the structure of the frame and mechanism.

147. (C.) *Copying and Drawing Machines.*—In copying-machines for enlarging or reducing drawings there is usually a combination of levers and linkwork connecting a tracing-point, which is moved over the lines of the original figure with a drawing-point, which draws the copy in such a manner that the velocity-ratio of their motions is a given constant quantity, and that the directions of their motions make a constant angle.

Mechanism, depending for its principles on the theory of the composition of rotations, is used to draw ellipses, epicycloids, epitrochoids, and other curves.

148. (D.) *Weighing Machines.*—In weighing machines the motion of the mechanism is used only for the purpose that its cessation, or its becoming an oscillation about a certain position, may indicate the equilibrium of the forces applied to the machine. Those forces may either be weights, which are to be compared with each other, or forces of other kinds, to be compared directly or indirectly with weights.

The machine for comparing weights, which is capable of the most minute accuracy, is also the simplest, being the *balance*, in which the equality of two weights is ascertained by their balancing each other at the ends of a lever of equal arms. In the *steelyard*, consisting either of one lever or of a train of levers, the unknown weight has an unchangeable point of application, and is compared with a known weight by shifting the latter along the lever to which it is applied until the machine is balanced; the ratio of the weights is then the reciprocal of the velocity-ratio of their points of application. The steelyard is more convenient for weighing very heavy loads than the balance, but not capable of such minute accuracy.

It is essential to accuracy in balances and steelyards that the friction should be less than the smallest admissible amount of error. To diminish the friction as much as possible, the axes of motion are all *knife-edges*, as they are termed, of steel or hardened iron, resting on hard surfaces of hardened iron or steel for ordinary purposes, and of some hard mineral, such as agate, for scientific purposes.

The weight of a column of fluid is determined by balancing it against a column of fluid whose weight is known, as in the barometer, where the weight of a column of the atmosphere is balanced against that of a column of mercury.

Weights are compared with each other indirectly, and other forces compared with weights, by means of their effects in bending a spring,—a convenient method, but not susceptible of minute accuracy.

The elastic pressure exerted by a fluid may be compared with weight, either by balancing the pressure against the weight of a column of liquid, or by maintaining a piston in equilibrio against that pressure, by means of a weight pressing it directly, or of a weight acting through a steelyard, or of the elasticity of a spring which has been compared with weights.

149. (E.) *Recording Machines.* — Recording-machines may be divided into two classes: *self-registering instruments*, which, by the aid of clockwork, record measurements either of space or of force, together with the instants of time at which these measurements were made; and *dynamometers*, already mentioned in chap. II. of this article, which register measurements of force, together with the space through which it has acted, thus recording energy or work.

150. *Working Machines Classed.*—The object or purpose of working-machines is to perform useful work; and their classification relatively to their objects and purposes is founded on the kind of useful work which they perform. In this point of view they may be classed as follows:—

A: Machines for lifting or lowering solid weights.
B: Machines for the horizontal transport of weights, either combined or not with lifting or lowering.
C: Machines for projecting solids.
D: Machines for lifting fluids.
E: Machines for propelling or projecting fluids.
F: Machines for dividing bodies.
G: Machines for shaping bodies by removing portions of them.
H: Machines for shaping bodies by pressure.
I: Machines for uniting bodies into fabrics.
J: Machines for printing.
K: Machines for producing sound.
L: Miscellaneous machines.

The author of this article does not pretend to assert that the above classification (taken to a considerable extent from the writings of Young and of Mr Babbage) exhausts all kinds of machines: he brings it forward merely as an attempt to introduce method to a certain extent into a subject which would otherwise be exceedingly confused.

151. (A.) *Machines for Lifting and Lowering Solids.*—The most common machines of this class are *capstans*, *cranes*, and *windlasses*. They are usually worked by manual labour, but sometimes by hydraulic engines, or by steam-engines. The useful resistance, when a load is lifted, being the weight of that load, is in general greater than the effort exerted by the prime mover, so that the mechanism has to be adapted to giving the working-piece a less velocity than the piece to which the effort is applied. In lowering solid loads the weight of the load acts as the effort, and the energy exerted by it is expended in overcoming the friction of a brake in order that the speed of descent may not be excessive.

152. (B.) *Transporting Machines.*—The mechanism of transporting machines consists of two parts: that by which the resistance is diminished, as the wheels and axles of vehicles; and that by which the resistance is overcome and the load propelled, comprising all kinds of locomotive and propelling machinery. Transporting machines are treated of in the articles relating specially to the lines of conveyance to which they are applied; such as CANALS, RAILROADS, ROADS, and STEAM NAVIGATION.

153. (C.) *Machines for Projecting Solids.*—This class comprehends all kinds of artillery.

154. (D.) *Machines for Lifting Fluids.*—(See Hydrodynamics and Pneumatics.)

155. (E.) *Machines for Propelling or Projecting Fluids.*—(See the same articles.)

156. (F.) *Machines for Dividing Bodies.*—This class comprehends all machines for separating solid masses into parts, whether by digging, cutting, sawing, grinding, tearing, crushing, pounding, pressing out fluids, or otherwise; and whether applied to earth, stones, metals, timber, fruit, grain, fibres, or other materials.

157. (G.) *Machines for Shaping Bodies by removing portions of them.*—This class of machines to a certain extent resembles the preceding. It includes machines for cutting, grinding, and polishing blocks of stone into required figures; shaping pieces of wood, metal, or other material, whether by *turning*, to produce spherical, cylindrical, and other curved surfaces,—by *boring*, *punching*, *slotting*, or *gouging*, to produce cylindrical, rectangular, or other orifices and grooves,—by *screw-cutting*, by *planing*, by *grinding* and *polishing*, to produce curved or plane surfaces. The most difficult and important of all these operations is to produce a surface truly plane; and the perfecting of this operation by Mr Whitworth is the most important step recently made in *Constructive Mechanics*, or the art of making machines and instruments. Next in point of difficulty may be placed the art of forming the concave reflecting surfaces of great specula for telescopes, such as those of the Herschels, of Mr Lassell, and of Lord Rosse.

158. (H.) *Machines for Shaping Bodies by Pressure* comprehend amongst others, *rolling-mills* for iron, *steam-hammers*, *wire-drawing* machines, *pinmaking* and *nail-making* machines, *coining* and other *stamping* machinery, *brickmaking* machines, *presses* for packing and compressing, &c., &c.

159. (I.) *Machines for Uniting Bodies into Fabrics* comprise *spinning* machinery, whether applied to ropes, yarn, or thread, *weaving* machinery of all kinds, *papermaking* machinery, *felting* machinery, and *sewing* machinery.

160. (J.) *Machines for printing* are used to apply either colouring matters or matters for discharging colour to paper, cloth, and other materials.

161. (K.) *Machines for Producing Sound.*—(See Acoustics, and Music.)

162. (L.) *Miscellaneous Machines.*—There are numerous machines which perform processes, especially in the preparation of textile fabrics for the market, which it would be almost impossible to class. Examples of such machines will be found by referring to the articles relating to the various branches of manufacture.

CHAPTER IV.—APPLIED ENERGETICS, OR THEORY OF PRIME MOVERS.

163. *Prime Movers in general: their Efficiency.*—Prime movers, or receivers of power, are those pieces or combinations of pieces of mechanism, which receive motion and force directly from some natural source of energy. The point where the mechanism belonging to the prime mover ends, and that belonging to the train for modifying the force and motion begins, is somewhat arbitrary; in general, however, the mechanism belonging to the prime mover may be held to include all pieces which regulate or assist in regulating the transmission of energy from the source of energy. Thus in the ordinary rotative steam-engine, the crank-shaft belongs to the prime mover, because it carries the eccentric which moves the valves, and the fly-wheel which stores and restores the periodical excess of energy of the engine, and drives the governor (when there is one) which regulates the admission of steam.

The *useful work* of the prime mover is the energy exerted by it upon that piece which it directly drives; and the ratio which this bears to the energy exerted by the source of energy is the *efficiency* of the prime mover.

It is often convenient to divide the prime mover into sections, and resolve its efficiency into factors, each factor being the efficiency of one of those sections. Thus the efficiency of a steam-engine may be resolved into the following factors:—

Efficiency of the furnace and boiler; being the proportion of the total heat of combustion of the fuel which takes effect in heating and evaporating the water.

Efficiency of the steam in driving the piston; being the proportion of the energy exerted by the steam on the piston (called the *indicated* energy or power, as being measured by an indicator), to the mechanical equivalent of the heat received by the water.

Efficiency of the mechanism from the piston to the crank-shaft inclusive; being the proportion of the effective energy transmitted by the crank-shaft to the indicated energy.

The product of those three factors is the efficiency of the engine as a whole.

In all prime movers the loss of energy may be distinguished into two parts; one being the unavoidable effect of the circumstances under which the machine necessarily works in the case under consideration; the other the effect of causes which are, or may be, capable of indefinite diminution by practical improvements. Those two parts may be distinguished as *necessary loss* and *waste.*

The efficiency which a prime mover would have under given circumstances if the *waste* of energy were altogether prevented, and the loss reduced to necessary loss alone, is called the *maximum* or the *theoretical* efficiency under the given circumstances.

For some prime movers there is a combination of circumstances which makes the theoretical efficiency greater than any other combination does. The theoretical efficiency under those circumstances is the *absolute maximum efficiency.*

The *duty* of a prime mover is its useful work in some given unit of time; as a second, a minute, an hour, a day. In some cases, such as that of the work of animals, the duty can be ascertained, while the efficiency can only be inferred indirectly or conjecturally from the want of precise data as to the whole energy expended.

164. *Sources of Energy Classed.*—The sources of energy used in practice may be classed as follows:—

A: Strength of men and animals.
B: Weight of liquids.
C: Motion of fluids.
D: Heat.
E: Electricity and magnetism.

165. (A.) *Strength of Men and Animals.*—The *mechanical daily duty* of a man or of a beast is the product of three quantities: the effort, the velocity, and the number of units of time per day during which work is continued. It is well known that for each individual man or animal there is a certain set of values of those three quantities which make their product the daily duty a maximum, and that any departures from those values diminishes the daily duty. Attempts have been made to represent by a formula the law of this diminution; they have met with imperfect success. That which agrees on the whole best with the facts is the formula of Maschek, which is as follows:—Let P_1 be the effort, V_1 the velocity, and T_1 the time of working per day, which give the maximum daily duty; let P, V, T, be any other set of values of those quantities. Then

$$\frac{P}{P_1}+\frac{V}{V_1}+\frac{T}{T_1}=3 \quad . \quad . \quad . \quad . \quad (109.)$$

One consequence of this formula is, that the best time of working per day for men, and for all animals, is *one-third part of a day*, or eight hours; a conclusion in accordance with experience.

The best effort P_1, and the best velocity V_1, are much less certain; the difficulty of determining their true mean values for particular species being rendered very great by the differences not only between individuals, but between races or varieties of the same species. The following table of values is proposed by Maschek as approximately true:—

Animals.	Weighing.	P_1	V_1	$\frac{T_1}{3600}$	P_1V_1	$P_1V_1T_1$
		lb.	Feet per second.	Hours per day.	Ft.-lb. per sec.	Ft.-lb.
Man	150 lb.	30	2·5	8	75	2,160,000
Horse (draught)	600 lb.	120	4·0	8	480	13,824,000
Ox............	600 lb.	120	2·5	8	300	8,640,000
Ass............	360 lb.	72?	2·5	8	180	5,184,000?
Mule	500 lb.	100?	3·5	8	350	10,080,000?

Of the numbers in this table those for the draught horse are probably the most accurate. For the thorough-bred horse it is certain that the value of V_1 is much greater, and that of P_1 much less, than for the draught horse; the effect being probably that the *maximum* daily duty $P_1V_1T_1$ is nearly the same; but experimental data are wanting to determine these quantities with precision.

The following table, chiefly extracted from the works of Poncelet and Morin, with the addition of some results of experiments by Lieutenant David Rankine and by the author of this article, shows the daily duty of men and horses under certain specified circumstances:—

	P	V	$\frac{T''}{3600}$	PV	PVT
	lb.	Feet p. sec.	Hours p. day.	Foot-lb. per sec.	Foot-lb. per day.
MAN—					
1. Raising his own weight up stair or ladder	143	0·5	8	72·5	2,088,000
2. Do. do. do.	...	...	10	...	2,616,000
3. (Tread-wheel—See 1.)					
4. Hauling up weight with rope	40	0·75	6	30	648,000
5. Lifting weights by hand	44	0·55	6	24·2	522,720
6. Carrying weights up stairs ...	143	0·13	6	18·5	399,600
7. Shovelling up earth to a height of 5 ft. 3 in.	6	1·3	10	7·8	280,800
8. Wheeling earth in barrow up slope of 1 in 12; ½ horiz. veloc. 0·9 ft. per sec. (returning empty)...............	132	0·075	10	9·9	356,400
9. Pushing or pulling horizontally (capstan or oar)	26·5	2·0	8	53	1,526,400
10. Turning a crank or winch	12·5	5·0	?	62·5	
	18·0	2·5	8	45	1,296,000
	20·0	14·4	2 min.	288	
11. Working pump	13·2	2·5	10	33	1,188,000
12. Hammering	15	?	8?	?	480,000
HORSE—					
13. (Thorough-bred) cantering and trotting, drawing a light railway carriage....	min. 22½ mean 30½ max. 50	14⅔	4	447½	6,444,000
14. Horse (draught) drawing cart or boat, walking......	120	3·6	8	432	12,441,600

166. *Horizontal Transport.*—When men and animals carry burdens, or draw or propel loads in certain vehicles, it is difficult, and sometimes impossible, to determine the duty performed in foot-pounds of work, because of the uncertainty of the amount in pounds of the resistance overcome. In this case, for the purpose of comparing performances of the same kind with each other, a unit is employed called a *foot-pound of horizontal transport*; meaning the conveying of a load of 1 pound 1 foot horizontally. The following table, compiled from the sources referred to in sect. 165, gives some examples of the daily duty of men and horses in units of horizontal transport; L denoting the load in lb., V the velocity in feet per second, and T the number of seconds per day of working:—

	L	V	$\frac{T}{3600}$	LV	LVT
	lb.	Feet per second.	Hours per day.	lb. conveyed 1 foot.	lb. conveyed 1 foot.
MAN.—					
15. Walking unloaded, transport of own weight........................	140	5	10	700	25,200,000
Do. do.	140	6	10	840	30,240,000
16. Wheeling load L in 2-wheeled barrow, returning empty; V = ½ velocity........................	224	1⅔	10	373	13,428,000
17. Do. 1 wheeled barrow do.	135	1⅔	10	225	8,100,000
18. Travelling with burden	90	2½	7	225	5,670,000
19. Conveying burden, returning unloaded	140	1⅔	6	233	5,032,800
20. Carrying burden for 30 seconds only	252	...	...	...	......
	126	11·7	...	1474·2	......
	0	23·1	...	0	......
HORSE.—					
21. Walking with cart always loaded	1500	3·6	10	5400	194,400,000
22. Trotting do. do.	750	7·2	4½	5400	87,480,000
23. Walking with cart, going loaded, returning empty; V = ½ mean velocity	1500	2·0	10	3000	108,000,000
24. Carrying burden, walking	270	3·6	10	972	34,992,000
25. do. trotting	180	7·2	7	1296	32,659,200

167. (B.) *Weight of Liquids.*—(C.) *Motion of Fluids.*—In water-wheels and other hydraulic engines the weight and motion of a liquid usually act together as sources of energy.

To determine the necessary loss of energy and the theoretical efficiency, let Q denote the weight of liquid which acts on the wheel or other engine per second; H the vertical fall from the point where the liquid first begins to act directly or indirectly on the wheel or other engine, to the point where it ceases to act; V_1 the velocity of the liquid when it begins to act; and V_2 the least velocity, when it ceases to act, which will properly discharge the liquid, and prevent its accumulating so as to impede the wheel or engine. Then the *power* or energy exerted per second is—

$$\left.\begin{array}{l} Q\left(H+\frac{V_1^2}{2g}\right); \\ \text{the \textit{necessary loss},---} \\ Q\cdot\frac{V_2^2}{2g}; \\ \text{the \textit{theoretical effect or useful work}} \\ \text{\textit{per second}---} \\ Q\left(H+\frac{V_1^2-V_2^2}{2g}\right); \\ \text{the \textit{theoretical efficiency}---} \\ \dfrac{H+\frac{V_1^2-V_2^2}{2g}}{H+\frac{V_1^2}{2g}}. \end{array}\right\} \quad . \; . \; . \quad (118.)$$

(For details as to the actual efficiency and duty, and the construction of water-wheels and other hydraulic engines, see HYDRODYNAMICS.)

In *windmills*, the air, being in motion, presses against and moves four or five radiating vanes or *sails*, whose surfaces are approximately helical, their axis of rotation being parallel, or slightly inclined in a vertical plane, to the direction of the wind. The best form and proportions for windmill sails, as determined experimentally by Smeaton, are as follows (see fig. 40):—Angle of each sail with the plane of rotation; at DE . . 18°

at BC . . 7°

OD = ⅙ of *whip* OA.

$$\text{Bar DE} = \frac{OA}{5};\ \text{bar BC} = \frac{OA}{3}.$$

AC = DE.

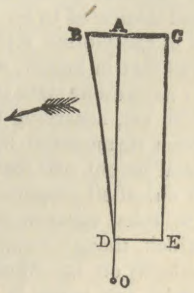

Fig. 40.

(Smeaton "On Windmills," in Tredgold's *Hydraulic Tracts.*)

168. (D.) *Heat.*—In sect. 163 the three factors into which the efficiency of an engine moved by heat can be resolved have already been stated. The efficiency of the furnace and boiler in steam-engines varies from 0·4 to 0·85. It may be considered that the loss of heat to the extent of 0·15 by the chimney, is necessary in order to produce a sufficient draught; any loss beyond this is *waste.* The theoretical efficiency of the *steam*, or *other elastic fluid* which serves as the mechanism for converting heat into mechanical energy, is regulated by a law which will now be explained.

Heat acts on bodies in two ways: to elevate temperature and make the bodies hotter, and to produce mechanical changes. Heat employed in producing mechanical changes disappears or becomes *latent*, as it is termed, and can be reproduced by reversing those mechanical changes. When a cycle of mechanical changes, ending by the restoration of the body to its original condition, produces mechanical energy, heat disappears to an amount equal to that which would be generated by employing the mechanical energy in overcoming friction; that is to say, a British unit of heat (or one degree of Fahrenheit in one lb. of liquid water) for every 772 foot-pounds of energy (being the constant already mentioned in sect. 121 as *Joule's equivalent*). This is called the *conversion of heat into mechanical energy.*

The *efficiency of the fluid* in a heat-engine is the proportion which the heat converted into mechanical energy bears to the whole heat received by the water or other fluid; and the *theoretical* or *maximum* value of that efficiency depends solely upon the respective temperatures at which the fluid receives heat and rejects the unconverted heat, according to the following law:—Let t_1 represent the temperature at which the fluid receives heat, and t_2 the temperature at which it rejects the unconverted heat, as measured from the *absolute zero;* that is, from a point 493°·2 Fahrenheit, or 274° Contigrade, below the temperature of melting ice. (Temperatures so measured are called *absolute temperatures.*) Then *maximum theoretical efficiency of the water or other fluid in a steam-engine or other heat-engine*—

$$= \frac{t_1 - t_2}{t_1} \quad . \; . \; . \; . \; . \quad (111.)$$

The necessary loss of heat by the fluid is $\frac{t_2}{t_1}$ of the whole heat received by it; and any loss beyond this is *waste.*

The theoretical efficiency of the steam in ordinary steam-engines seldom exceeds $\frac{1}{5}$th; the greatest actual efficiency is about $\frac{1}{6}$th; the efficiency in good ordinary engines is about 0·1 or 0·08, and in bad and wasteful engines 0·04, or even less. (For details, see STEAM-ENGINE.)

169. (E.) *Electricity and Magnetism.*—Electricity developed by chemical action in a galvanic battery has been to a small extent used to produce mechanical energy by alternately magnetizing and unmagnetizing soft-iron bars.

The data for determining the actual efficiency of such engines are deficient. Their theoretical efficiency depends on the following law demonstrated by Mr Joule:—

Let γ_1 denote the strength of the electric current which would be developed in the conducting wire of the battery if there were no iron bar to be magnetized; γ_2 the strength to which the current is reduced by the reaction of the iron bar, tending to induce a contrary current. Then the theoretical efficiency of the engine is

$$\frac{\gamma_1 - \gamma_2}{\gamma_1}. \quad . \; . \; . \; . \; . \quad (112.)$$

The proportion of the energy expended, which is *necessarily lost*, is $\frac{\gamma_2}{\gamma_1}$, and is employed in producing heat in the conducting circuit.

This law is exactly analogous to that of the theoretical efficiency of heat-engines given in equation 111.

There is reason to believe that electro-magnetic engines are capable of a higher efficiency than heat-engines; but the greater cost of the materials consumed renders them much less economical commercially.

170. *Transformation of Energy in General.*—The laws of the efficiency of heat-engines and electro-magnetic engines are particular cases of a general law which regulates all *transformations of energy.* (See *Proceedings of the Philosophical Society of Glasgow*, January 1853; *Edinburgh Philosophical Journal*, July 1855.)

171. *Recent Authorities.*—On the subject of applied mechanics in general the following are some of the best recent authorities:—Poncelet, *Mécanique Industrielle;* Morin, *Notions Fondamentales de Mécanique;* Moseley's *Mechanics of Engineering and Architecture;* Whewell's *Mechanics of Engineering.* Other authorities have been referred to in the course of the article. (W. J. M. R.)

MECHLIN (Flemish *Mechelen*, French *Malines*), a town of Belgium, province of Antwerp, in the midst of a rich level country on both sides of the Dyle, 14 miles S.S.E. of Antwerp. The town is well built, and has broad and clean streets, as well as a large and handsome square called the Place d'Armes. The most remarkable edifice in Mechlin is the cathedral, built in the fifteenth century, and dedicated to St Rombaud. This fine building, which is in the Gothic style of architecture, has a square tower 348 feet in height, with a fine peal of bells; and although in its present state it is nearly as high as St Paul's in London, yet, according to the original design, it was to have been surmounted by a spire which would have made the total height 640 feet. Even the present tower, however, is out of all proportion to the body of the building. The cathedral contains a picture of the Last Supper by Rubens, which, though in some respects a fine picture, is not considered on the whole to be a favourable specimen of its artist, and is not in a good state of preservation. There are several side-chapels containing pictures, of which the most celebrated is the "Crucifixion," by Vandyke, which was declared by Sir Joshua Reynolds to be not only the best of the productions of that painter, but also one of the finest paintings in the world. The pulpit is adorned with a carved representation of the Conversion of St Paul. There are several other churches in Mechlin, some of which contain pictures by Rubens. Of these, the finest is that of the "Adoration of the Magi," in the church of St John. The other remarkable buildings in Mechlin are,—the archbishop's palace, a modern edifice, which, though plain, is handsome; the Beguinage, an asylum for aged women, having a chapel with a beautiful front attached; the arsenal and cannon foundry; and the town-hall. The town also possesses a college, an academy of paintings, a society of fine arts, a botanic garden, and several charitable institutions. Mechlin has long been distinguished by the manufacture of fine lace; but this branch of industry has in the present day much fallen off, and there are now only eight houses in operation; while the lace made here is coarser and less valuable than that of Brussels. There are also manufactures of straw and felt hats, woollen and linen fabrics, oil, leather, candles, paper, &c. Mechlin possesses several breweries, and the beer which is produced is of a peculiar quality, and acquires, when kept, a flavour resembling that of wine. Among the articles for which Mechlin is famous is a sort of gingerbread, and the *déjeûner de Malines*, a dish much esteemed by epicures, made up of pigs' ears and feet, along with other ingredients.

The trade of the place is considerable; the principal articles are corn, oil, hemp, and flax, together with the various products of manufacture. The town also derives much importance from its situation on a navigable river and a canal to Louvain, as well as from being the place of junction of four lines of railway. The earliest period to which the history of Mechlin can be traced is the fifth century; when it seems to have been a place of some importance, and the capital of a lordship. It then belonged to the French. It was sacked by the Normans in the ninth century; and in 910 was given over to the Bishop of Liège. In the fourteenth century it had risen to great importance; but in after times it suffered many calamities, especially from the ravages of war. Sacked by the Spanish troops in 1572, it was again taken, six years after, by the Prince of Orange. Mechlin was captured by Marlborough in 1706, and by the French in 1746. Finally, it was again taken by the French in 1792, by whom, in 1804, its fortifications were destroyed. Pop. (1851) 30,372.

MECHOACAN, a province of Mexico. (See MEXICO.)

MECKEL, JOHANN FRIEDREICH, was born at Halle in 1781, of a family of some note in the annals of medicine. On receiving his doctor's degree at the university of his native town, he already gave evidence of the possession of distinguished talents for physical research by his inaugural thesis *De Conditionibus Cordis Abnormibus.* Having directed his attention almost exclusively to the study of comparative anatomy, he undertook travels into Germany, Italy, and France, to widen the sphere of his observation, and perfect his knowledge of his favourite science. After his return to Halle in 1809, he published a translation of the *Leçons d'Anatomie Comparée* of Cuvier, enriched with notes containing new and interesting observations. He was subsequently appointed professor of anatomy and physiology in his native university; and gave to the world in 1813 his Essay on Comparative Anatomy, which formed a fitting prelude to his great work, *System des Vergleichenden Anatomie*, 5 tom., Leipsic, 1821–31, which established Meckel's scientific reputation. In addition to various memoirs on anatomy, he likewise published a work entitled *Tabulæ Anatomico-Pathologicæ, modos omnes quibus partium corporis humani omnium forma interna atque externa à normâ recedit, exhibentes*, Lipsiæ, 4 vols. fol., 1817–26. He laboured for a long time with great industry in perfecting the excellent collection commenced by Reil, and known at the present day by the name of the *Physiological Archives* of Meckel, 12 vols. 8vo, Halle, 1815–1827. After gaining for himself a distinguished name among the most eminent scientific men of Germany, he died at Halle on the 13th of October 1833, aged fifty-two years.

MECKLENBURG, a territory of Northern Germany, lying between 53. 8. and 54. 2. N. Lat., and between 10. 40. and 13. 45. E. Long., is bounded on the N. by the Baltic, E. and S. by Prussia, and W. by Hanover, Denmark, and Lübeck. It consists of the two grand duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz; and has a total area of 5588 square miles.

1. *Mecklenburg-Schwerin* consists of a low tract of country, forming part of the plain of N. Germany. It is, however, by no means destitute of elevations or depressions; these are numerous, but not very marked; and the only hills of any importance in the duchy are those of the Ruhneburg, which separate the waters of the Elbe from those of the Baltic; but they do not exceed 600 feet in height. The duchy contains numerous lakes of considerable size, the largest of which, Lake Muritz, is 18 miles in length by 8 in breadth. The principal rivers are,—the Trave, Stepenitz, Warnow, Recknitz, and Peene, flowing into the Baltic; and the Elde and Havel, which join the Elbe. The sea-coast is not much indented, but there are a few large bays, of which the most extensive is that of Wismar. In some places the shore is steep and elevated, and in others low and sandy. The nature of the soil varies very considerably in different parts. On each side of the central ridge there is a tract of land consisting of sandy heaths and moors; near the sea, too, the country is of a sandy character; but the greater part of the surface consists of rich and fertile ground, covered in some places with large forests, and presenting in general a picturesque and lively aspect. The scenery of many of the lakes and of the sea-coast is very beautiful. Although the climate of Mecklenburg is mild, the cold in winter is severe; and the moisture of the soil and atmosphere gives rise to frequent fogs, which render the country somewhat unhealthy. The people are chiefly employed in agriculture; and the land is divided into extensive farms, which are well cultivated. The principal crops raised are,—wheat, rye, barley, oats, peas, beans, potatoes, and turnips. The timber from the forests, and which consists of oak, beech, and fir, is of excellent quality. Horses, cattle, and sheep, are numerous in the duchy, and of good breed. Mecklenburg, besides, has large herds of swine, which wander over the country; and extraordinary numbers of geese, which stock the rivers and lakes, and which supply a great part of Europe with quills, and are much esteemed for their large size and excellent quality. Minerals exist but scantily, and mines not at all, in Mecklenburg. The manufactures consist chiefly of linen and woollen stuffs; while there are also breweries, distilleries, cotton factories, paper-mills, &c.; but although encouraged by the government, they are on the whole unimportant. The trade of Mecklenburg is of more value, and consists in the export of agricultural and manufacturing produce. This flourishing condition of commerce is to be ascribed in a great measure to the favourable position of the country between the Baltic and the Elbe, and to the comparative freedom of the trade from the restrictions of duties and imposts. The peasantry were till a recent period in a state of serfdom, such as was common throughout Europe in the middle ages; but the last trace of this disappeared by law in 1820, and in fact in 1825. A great part of the inhabitants are nobles; but of these the greater number, though "proud of pedigree, are poor of purse," and are obliged to condescend often to the most menial employments to gain a livelihood. The executive power of the duchy is in the hands of the sovereign; and the legislature consists of two estates—the landowners, amounting to about 572; and the deputies of the 44 towns, who are more than 200 in number. This body forms the legislature of the two duchies together, and meets annually, alternately at Sternberg and Malchin. They have, however, no power to originate motions, but must decide on the proposals submitted to them by the sovereign. The established religion, and that of the majority of the people, is Lutheran; there are, however, a few Calvinists, Romanists, and Jews. The duchy contains a university at Rostock, and many public schools throughout the country. The revenue of Mecklenburg-Schwerin for the year ending June 1854 amounted to L.480,193, and the expenditure to L.500,211. Pop. (1854) 538,997.

2. *Mecklenburg-Strelitz* is distinguished by the same general physical features as the other duchy. The surface, however, is in general lower than Mecklenburg-Schwerin; and the inhabitants are, like those in the adjoining district, chiefly employed in agriculture. The government is of the same nature as that of Mecklenburg-Schwerin, with which it is very closely connected; and the two duchies together hold the fourteenth place in the German Confederation, and have a single vote in the Select Council. In the full diet, however, Mecklenburg-Schwerin has two suffrages, and Mecklenburg-Strelitz only one. Pop. (1851) 99,628.

The most ancient inhabitants of Mecklenburg were the

Vandals, who afterwards migrated southwards, and the country was taken possession of by the Obotriti and other Slavonic nations. The ancestor of the present ducal family of Mecklenburg was Pribislav, who was made a prince of the empire by Charles IV. in 1340. Mecklenburg was afterwards given by Ferdinand II. to Wallenstein, and was conquered in more recent times by Napoleon; but the reigning family was always restored, and in 1815 assumed the title of Grand Dukes. The House of Mecklenburg is thus one of the most ancient in Europe; and by the marriage of a princess of that family to George III. of England, is connected with the royal family of Great Britain.

MEDALS. See Numismatics.

MEDE, Joseph, a learned English divine, was born at Berden in Essex in October 1586. While attending school at Wetherfield in his native county, he taught himself Hebrew from a copy of Bellarmine's Grammar, which he had picked up during a visit to London. He entered Christ's College, Cambridge, at the age of sixteen, and took his degree of M.A. in 1610. At this time his accomplishments and his devotion to study might have set him on a fair road to church preferment; but, passionately fond of academic retirement, he settled down contentedly in a fellowship which he obtained through the interest of Bishop Andrews. Soon after this he was appointed reader of the Greek lectures of Sir Walter Mildmay's foundation, an office which he occupied till his death. The time not occupied with these duties was spent in the study of history, both sacred and profane, and in applying his acquisitions in that branch of knowledge to the elucidation of Holy Writ. In 1618 he took the degree of Bachelor of Divinity, and modesty alone prevented him from taking that of Doctor. In 1627 Archbishop Usher paid a tribute to his learning and worth by recommending him to the provostship of Trinity College, Dublin; but this appointment Mede declined, nor had he altered his mind when the offer was repeated in 1630. Not less remarkable for piety than for learning, he was a strenuous promoter of the design for the universal pacification among Protestants; and he regularly devoted a tithe of his income to charitable and pious purposes. He died in October 1638.

Mede's principal work is his *Clavis Apocalyptica*, published in 1627, and translated into English in 1643. According to Bishop Hurd, it was the first rational attempt to interpret the Apocalypse. A collection of Mede's works was published, with a Life by Dr Worthington, in 1 vol. folio, London, 1672.

MEDEA, a celebrated sorceress in Greek mythology, was the daughter of Æetes, King of Colchis. Her mother is variously supposed to have been Idyia, Eurylyte, Hecate, and Antiope. (Apollod. i., Schol. Apollon. iii., Schol. Hesiod. 957, Hygin. 25.) Medea first appears in fabulous history at the time when the Argonauts landed in her father's kingdom. She then became enamoured of Jason, the leader of the expedition, and promised him her assistance on condition that she should become his wife and return with him to Greece. By her magical arts the Golden Fleece, the object of the enterprise, was obtained, and she set sail with her betrothed in the ship Argo. Æetes, however, gave chase, and was on the point of overtaking the fugitives, when Medea murdered her brother Absyrtus, tore him to pieces, and strewed the sea with his bleeding limbs. The father tarried to gather up the remains of his son, and his daughter escaped, and continued on her course towards Iolcus, the native city of her husband. On arriving at the land of the Phæacians, the Argonauts and their companions were overtaken by the Colchians, who demanded the restoration of Medea. The case was then brought before Alcinous, King of Phæacia, who decided that Medea must be given up unless she was married to Jason; but, by the assistance of his wife Arete, the marriage was hurriedly performed, and Jason was allowed to take his wife with him to Iolcus, without any further delay or hinderance. There Jason learned for the first time that his brother had been murdered, and that his father and mother had been driven to commit suicide by the ruler Pelias. He therefore called upon Medea to employ all her arts for the purpose of revenge. The sorceress summoning the daughters of Pelias, showed them by actual experiment how an animal might be restored to youth by being seethed in a cauldron, and persuaded them to try the same process on their aged father. The limbs of Pelias failed to be revived, and thus the revenge of Jason was glutted. Owing to this barbarous deed, Medea and her husband were forced to quit Iolcus. Another version of the story is given by Ovid, who relates that on his return to Iolcus, Jason found his father Æson still alive, and that he was restored to youth by the arts of Medea. Medea and Jason then fled to Corinth, and there, after the lapse of ten years, Jason fell in love with Glauce or Creusa, daughter of Creon, King of Thebes. Full of revenge at being thus deserted, Medea presented her rival with a poisonous garment, which, as soon as it was put on, consumed its new owner to ashes. She then killed her own sons, Pheres and Mermerus, and escaping from the enraged father, fled through the air in a chariot drawn by winged dragons. Alighting at Athens, she underwent the purification for murder, and was then married to King Ægeus. In no long time, however, she began to plot the destruction of Theseus, the son of her husband by a former marriage; but her intentions having been discovered, she was again compelled to mount her airy chariot and flee. According to one account, she repaired to Asia and gave to the nation of the Medes their name. (Paus. ii., Ovid. *Met.* vii.) But other authorities state that she returned to her native Colchis, and, with the aid of her son Medus, restored her father Æetes to his throne. (Apollodor. i.) Medea is also said to have become latterly reconciled to Jason. (Tacit. *Ann.* vi.) After death she was married to Achilles in the Elysian Fields. (Schol. Apollon. iv.) The story of Medea is the subject of several tragedies. Those of Euripides and Seneca are the most famous.

MEDELLIN, a city of South America, capital of a province of the same name, in the department of Cundinamarca, New Granada, is situated on the Porse, a small affluent of the Cauca, 40 miles S.E. of Antioquia. It carries on a considerable trade in the products of the district; and had in 1851, 14,800 inhabitants.

MEDGYES, Mediasch, or Medwisch, a royal free town of Transylvania, capital of a district of the same name, stands on the left bank of the Great Kokel, 38 miles E. of Carlsburg. It is surrounded by walls, with six gates; and has a Roman Catholic, Calvinistic, and Greek churches, a Franciscan monastery, and a gymnasium with small library. It has some trade in wine, the produce of the district. Pop. 6200.

MEDIA, a country in the western part of Asia, was bounded, according to Ptolemy, on the N. by part of the Caspian Sea; on the S. by Persia proper, Susiana, and Assyria; on the E. by Parthia and Hyrcania; and on the W. by Armenia and Assyria. It was anciently divided into the provinces of Tropatene, Charomithrene, Darites, Marciane, Amariace, and Syro-Media. In a later division, however, all these were reduced to two—*Media Magna*, and *Media Atroptia*, or *Atropatene*. Media Magna was bounded by Susiana, Parthia, Hyrcania, the Caspian Sea, and Atropatene, and contained the cities of Ecbatana, Hamadan, Laodicea, Ragæ, &c. The greater part of Media Magna is lofty and mountainous, with a cold climate, especially in the northern parts. The southern region, however, consisting of plains and valleys, was in the time of

Strabo productive of all sorts of vegetables, except the olive. This region was also celebrated for its pasturage and for its horses; the Nisæan plain especially being devoted to the rearing of those animals, and containing the royal herds of the Persian monarchs, amounting, it was said, to no less than 50,000 in number. This country, in addition to the money tribute, supplied to the Persian empire 30,000 horses, 40,000 mules, and 100,000 sheep; so great at that time were its pastoral riches. (Strabo, xi., p. 525.) Media Atroptia, or Atropatene, lay between the Caspian Mountains and the Caspian Sea. Media derived its name from Madai, the third son of Japhet; as is plain from Scripture, where the Medes were constantly called *Medai*. Amongst profane authors, Strabo derives the name from Medus, the son of Jason and Medea, others from Medea herself, and some from the *medial* position of the country. Sextus Rufus tells us that in his time it was called *Medena;* and from Herodotus we learn that its inhabitants were called *Arii*.

The government of the various tribes into which the country was divided was originally monarchical, and they seem to have had their own kings even in the earliest times. They were first brought under a foreign yoke by Pul, said to have been the founder of the Assyrian monarchy, or by his immediate successor Tiglath-Pileser. From the time of Pul, or Tiglath-Pileser, who succeeded his father in the year 740 B.C., they remained subject to the Assyrians till about the latter end of the reign of Sennacherib, 710 B.C., when, emancipating themselves from Assyrian bondage, they fell into a state of anarchy. It was accordingly found necessary to appoint a king; upon which Dejoces was named to the sovereignty, and with universal applause placed upon the throne 710 B.C. No sooner had he been vested with the supreme power, than he threw off the mask and became a tyrant. Ecbatana was built and chosen for the royal residence, and a stately palace was erected. Dejoces having enacted various laws for the government of the kingdom, and having in a considerable degree civilized his unpolished subjects, entertained thoughts of extending the limits of his new kingdom, and with this view he invaded Assyria. Nebuchodonosor, however, at that time king of Assyria, met him in the plain of Rhagæ, and a battle ensued, in which the Medes were utterly defeated, and Dejoces was slain, after a reign, according to Herodotus, of fifty-three years. The Assyrian king, following up his success, reduced several cities of Media, and almost utterly destroyed Ecbatana. Dejoces was succeeded by his son Phraortes 647 B.C. This prince, not satisfied with the kingdom of Media, invaded Persia, and is said to have brought that nation under subjection. Such is the account of Herodotus. Others, however, ascribe the conquest of Persia, not to Phraortes, but to his son and successor Cyaxares. Phraortes, however, subdued several neighbouring nations, and made himself master of almost all Upper Asia, lying between Mount Taurus and the River Halys. Emboldened by his success, he invaded Assyria, subdued a great part of the country, and even laid siege to Nineveh, the metropolis. He fell before that city in the twenty-third year of his reign.

His son Cyaxares was not less valiant and enterprising than his father, and had better success against the Assyrians. With the remains of that army which had been defeated under Phraortes, he not only drove the conquerors out of Media, but obliged Chyniladan to shut himself up in Nineveh. To this place he immediately laid close siege; but was obliged to abandon the enterprise on account of an irruption of the Scythians into his own country. Cyaxares engaged these new enemies with great resolution, but was utterly defeated; and the conquerors overran not only all Media, but the greater part of Upper Asia, extending their conquests into Syria, and as far as the confines of Egypt. They continued masters of this vast tract of country for twenty-eight years, till at last Media was delivered from their yoke by a general massacre at the instigation of Cyaxares.

The Medes afterwards encountered the Lydians; and during the engagement there happened a total eclipse of the sun, which is said to have been foretold by Thales the Milesian. Both nations were terrified, and soon afterwards concluded a peace by the mediation of Nebuchadnezzar, King of Babylon, and Syennesis, King of Cilicia. This peace was confirmed by the marriage of Aryenis, the daughter of Halyattes, and Astyages, the eldest son of Cyaxares; and of this marriage was born in the ensuing year Cyaxares II., who, in the book of Daniel, ch. v. 31, is called Darius the Mede. Cyaxares, disengaged from the Lydian war, resumed the siege of Nineveh; and having formed a strict alliance with Nebuchadnezzar, King of Babylon, they joined their forces, and took and destroyed the city (606 B.C.). With this prosperous event commenced the great successes of Nebuchadnezzar and Cyaxares; and thus was laid the foundation of the two collateral empires, as they may be called, of the Medes and Babylonians, which rose upon the ruins of the Assyrian monarchy. After the reduction of Nineveh, the two conquerors led the confederate army against Pharaoh-Necho, King of Egypt, defeated him near the Euphrates, and compelled him to resign what he had formerly taken from the Assyrians. After this victory they reduced all Cœlesyria and Phœnicia; they then invaded and laid waste Samaria, Galilee, and Scythopolis; and at last besieged Jerusalem, and took Jehoiakim prisoner. Nebuchadnezzar afterwards pursued his conquests in the West, and Cyaxares subdued the Assyrian provinces of Armenia, Pontus, and Cappadocia. Again uniting their forces, they reduced Persia and Susiana, and accomplished the conquest of the Assyrian empire. The prophet Ezekiel (ch. xxxii. 22, &c.) enumerates the chief nations who were subdued and slaughtered by the two conquerors Cyaxares and Nebuchadnezzar.

After this victory the Babylonian and Median empires seem to have been united; but upon the death of Nebuchadnezzar, or rather towards the close of his life, a war ensued, which was only extinguished by the dissolution of the Babylonian empire. The Medes, under Astyages, the son of Cyaxares I., withstood the power of the Babylonian monarchs, and, under Cyrus and Cyaxares II., utterly destroyed their empire by the taking of Babylon. After the death of Cyaxares II. the kingdom fell to Cyrus, by whom the seat of the empire was transferred to Persia. After the time of Cyrus, the union between the Medes and Persians became so close that many of the customs of the latter are believed to have been derived from Media; and the name by which the Persians were known to the Greeks was that of Medes, while in sacred history they are always called Medes and Persians. On the dismemberment of the Persian empire they came under the dominion of the Seleucidæ, and subsequently of the Parthians.

The Medes were fond of equestrian exercises, and were great adepts in archery. The priests of the Median religion were called *Magi;* and the principal objects of worship were the sun, moon, and five planets. The seven concentric walls of Ecbatana, the capital, were, according to Herodotus, decorated with various colours, which were probably symbolical of these objects of adoration; and the correctness of this description has been recently confirmed by the discovery of similarly coloured terraces at Birs Nimroud, near the ruins of Babylon.

MEDICAL JURISPRUDENCE.

History.

The connection between medicine and legislation had been perceived long before it was considered as a peculiar branch of study, or had even obtained a distinctive appellation. Since its importance has been recognized, it is known in Germany, the country in which it took its rise, by the name of STATE MEDICINE; in Italy and in France it is termed LEGAL MEDICINE, and with us it is usually denominated MEDICAL JURISPRUDENCE, or FORENSIC MEDICINE. It is founded on the relations which ought to subsist between human nature and social institutions, and consists in the application of the principles of medical science to the administration of justice, and to the preservation of the public health. Its nature and objects will be best elucidated by a sketch of its progress.

HISTORY OF LEGAL MEDICINE.

Notwithstanding the importance of the objects which it embraces, and their intimate relation to the interests of society, the true origin of Medical Jurisprudence is of comparatively recent date. It is true that traces of its principles may be perceived in very remote times. In the Mosaic institutions the judges are enjoined to consult the *priests*, who were the sole physicians of that age and country, on the modes of distinguishing leprosy from other diseases, on the marks of defloration, and the examination of wounds. In the slight notices handed down to us of the ancient code of Egypt, attributed to Menes, we may observe one trace of the influence of medicine on legislation, in the law which forbade the infliction of corporal punishment on a pregnant female; but among the ancient states of Greece the principles of medical science, though successfully cultivated, seem scarcely to have been applied to legislation, except in certain questions respecting the legitimacy of children, a subject on which the notions even of Aristotle were not very definite. In the writings of Galen, however, we find more distinct traces of legal medicine; as in his various remarks on the difference between the lungs of a fœtus and of an adult, in his treatise on simulated diseases, and in his observations on the legitimacy of seven months' children.

The laws of ancient Rome were borrowed from Greece, and we could scarcely expect to find in them a more refined legislation; but it is worthy of notice, that the laws of the Twelve Tables fix on 300 days as the extreme duration of utero-gestation, the precise term fixed by the Code-Napoleon. Some writers contend that the Roman law authorized the inspection of dead bodies by medical men, because of the twenty-three wounds by which Cæsar fell, the physician Antistius pronounced one only mortal; and because Tacitus has spoken of the marks of poison on the bodies of Germanicus and Agricola: yet we have no proof that such opinions were required by any positive law, or that the judge was in the habit of demanding the assistance of the physician. In the Justinian code, however, we find more obvious traces of the relation between medicine and law; as in the titles *De statu Hominum; De Pœnis et Manumissis; De Sicariis; De Inspiciendo ventre Custodiendoque partu; De Muliere quæ peperit undecimo mense; De Impotentiâ; De Hermaphroditis:* yet in the Justinian code it was not by the testimony of living medical witnesses that such quesions were to be decided, but "on the authority of the learned Hippocrates."

History.

It was chiefly on questions of medical police, as to what regarded the salubrity of cities and stations, that the ancient Greek or Roman magistrates had recourse to medical assistance; and it appears that it was to such subjects that the public functions of the *Archiater* of the lower empire were confined.

Medical Jurisprudence, as a science, cannot date farther back than the 16th century. Various German emperors had in vain attempted the introduction of an uniform criminal code; but George, bishop of Bamberg, in 1507, proclaimed a penal code, drawn up for his states by *Baron Schwartzenberg*, in which the necessity of medical evidence, in certain cases, was recognized: and though this improvement was for some time resisted by the greatest part of Germany, the emperor Charles V. eventually succeeded in persuading the diet of Ratisbon, in 1532, to adopt a uniform code of German penal jurisprudence, founded on that of Bamberg, in which the civil magistrate was, in all cases of doubt or difficulty, enjoined to obtain the evidence of medical witnesses; as in cases of personal injuries, infanticide, murders by poison or other means, pretended pregnancy, simulated diseases, &c. The celebrated *Constitutio Criminalis Carolina* was published in 1553; this must be considered as the true dawn of Legal Medicine, and Germany the country which gave it birth. To the same country must be ascribed the glory of having first thrown the shield of medical science over the victims of a dark fanaticism. The belief in the powers of witches and sorcerers was in full force in the 16th century. It is computed that in Lorrain above 900 persons were burnt alive within 19 years, for the imputed crime of sorcery; and that in the Electorate of Treves alone, within a few years, 6500 individuals had perished in the flames for the same imaginary crime. In Germany and France instances of pretended demoniacal possession were perpetually occurring; and at Freidberg public prayers were offered up to assuage that dire affliction. Weiher, physician to William, duke of Cleves, had the boldness to impugn these superstitious notions, in a tract published at Basle in 1564, and undertook to prove that witches and demoniacs ought to be considered as unhappy persons subject to hypochondriasis and hysteria, whose maladies should rather excite pity, than render them obnoxious to punishment; while he ridiculed the ordinary modes by which these unfortunate beings were proved to be guilty of the alleged crimes. This attack on a popular superstition aroused alike indignation and vengeance against the daring innovator; and, but for the powerful intercession of his patron, Weiher himself would have perished in the flames, from which he had tried to save others.

In the close of that century many treatises on different branches of Legal Medicine appeared in various countries. Ambrose Paré wrote on monstrous births, on simulated diseases, and a memoir on the art of drawing up medical reports. In 1598 Severin Pineau published at Paris the treatise *De Notis Integritatis et Corruptionis Virginum;* a book still quoted as an authority. The first *system of Legal Medicine* appeared about the same time in Sicily, in the work of Fortunato Fidele *De Relationibus Medicorum;* in which, as might be expected in his age and country, the opinions of the physician are too much warped by his servile deference for the canon law and its clerical expounders.

The rapid progress of anatomy in the commencement of the 17th century now became apparent in the invaluable *Quæstiones Medico-Legales* of Paulo Zacchia, which appeared in successive volumes from 1621 to 1635; a work which will ever be regarded as a landmark in the history of Legal Medicine; and which, by its learning and its sagacious indications, in an age in which chemistry was in its infancy, and physiology very imperfect, places the medical acumen of the great Roman medico-jurist in a very favourable point of view.

The noble discovery of the circulation of the blood gave a new light to physiological reasoning, which was broadly reflected on Legal Medicine: and to Harvey we also owe the idea how the application of Galen's remark, respecting the difference between the adult and the fœtal lungs, might be applied to elucidate cases of infanticide.

About the same time appeared two valuable treatises by Melchior Sebiz, *De Notis Virginitatis*, and *Examen Vulnerum*. In the first he maintained that the existence of the hymen was the real mark of virgin purity; an inference warmly denied by Orazio Augenio and Pietro Gassendi: in the second he pointed out the importance of distinguishing between wounds *incidentally* and *necessarily* fatal.

In 1663 Thomas Bartholin, a Danish physician, carefully investigated the period of human utero-gestation, and proposed the *Hydrostatic Test*, or observing whether the lungs of the infant floated or sunk in water, as proving whether it had ever breathed. The rationale of this process was more fully explained by Swammerdam in 1677; but was first applied to practical use by Jan Schreyer in 1682; after having been investigated by Thruston and Rayger.

While these important steps were in progress, Germany set the example of the first public prelections on Medical Jurisprudence. About the middle of the 17th century, Michaelis gave the first course in the university of Leipzig: these were soon followed by the lectures of the celebrated Bohn, who, before the close of the century, had published his valuable works *De Renunciatione Vulnerum, et Dissertationes Medicinæ Forensis*, which were speedily succeeded by the tract *De Officiis Medici Duplicis, Clinici et Forensis*. The two first were nearly contemporary with the investigations of Welsch and Amman *on the fatality of wounds*, and the celebrated work of Licetus *De Monstris*; and the latter with the valuable *Sepulchretum* of Bonnet.

The mode of conducting medico-legal investigations had attracted attention in France, from the time of Ambrose Paré, through the 17th century. French authors love to trace the rudiments of the science in their country from the 12th century, in the rules given in the *Assizes of Jerusalem*, for drawing up exemptions from certain civil and military duties, and in several subsequent ordonnances of their monarchs, for the inspection of wounds: enactments from which we may trace the institution of the *Chirurgiens du Châtelet*. In 1603 Henri IV. authorized his physician to appoint persons, skilled in medicine and surgery, to make judicial inspections and reports in all cities and royal jurisdictions. The difficulty of carrying this into effect induced Louis XIV. to create, in 1692, *hereditary royal physicians and surgeons*, for the same purpose, with various immunities and privileges; but their corruption and venality soon became notorious, and the office was suppressed in 1790.

Various decrees, however, of the parliament of Paris, from the middle to the end of the 17th century, were directed to the improvement of legal medicine; and that body acquired great celebrity by the general equity and good sense of its judgments. Notwithstanding this auspicious commencement, Legal Medicine did not then flourish in France; and the work of Gendry, *Sur les Moyens de bien rapporter à Justice*, shews how imperfect were the then approved modes of investigation; though it proves that the importance of the subject began to be acknowledged. No other French work on Legal Medicine appeared in that century, with the exception of *Doctrine des rapports en Chirurgie* of Blégny, which was superseded in the beginning of the succeeding century by the more useful *L'art de faire des rapports en Chirurgie* of Devaux.

The 18th century commenced with happier auspices for our science, and the press teemed with important works on Legal Medicine. As early as 1700 the admirable treatise on the diseases of artificers by Bernardino Ramazzini appeared at Padua. In the following year Valentini published his *Pandectæ Medico-legales*; his *Novellæ* appeared in 1711; and both were incorporated in the excellent *Corpus Juris Medico-legale* in 1722. This work contains a judicious view of all that had been done before him, and is a vast storehouse of medico-legal information.

Several professorships for teaching this subject were about that period founded in the German universities; and the succession of German writers becomes now so numerous that we cannot attempt to give a catalogue, far less to characterize their works. Zittman, Boerner, Kannegeiser, and Teichmeyer, each published systems of various yet acknowledged merit. The *Institutiones Medicinæ Legalis* of the latter long formed the manual of the student: the clear and forcible reasoning of Storch in his work *De Medicinæ Utilitate in Jurisprudentia* (1730), vindicated the high importance of this branch of knowledge: but the *Systema* of Alberti, professor of Legal Medicine at Halle, in six quarto volumes, was the most complete and laborious work ever published on this subject. The writings of this learned man are obscured by his attachment to the mysticism of the Stahlian school; yet the industry with which he has collected facts renders his work a precious mine of information. Curious additions to our knowledge were made by the smaller publications of Loewe, Richter, Budæus, Troppanneger, Fritch, and Wolff, Hermann, Clauder, Herzog, and Parmeon; which are chiefly valuable to those who may be called to exercise the profession in Germany. In the *Bibliothèque Medicale* of Ploucquet will be found the names of those who have dedicated themselves to the illustration of particular branches of this extensive subject; and in the *Collectio Opusculorum* of Schlegel will be found some of the best detached treatises of the first three-fourths of the last century on the subject of wounds, poisoning, infanticide, utero-gestation, insanity, and the legal inspection of dead bodies. About the same time appeared the *Anthropologia Forensis* of Hebenstreit, the *Specimena* of Fursteneau, the *Institutiones* of Ludwig, and the *Elementa* of Fazelius. The lectures of Haller belong to this same period, though they were not published till 1781–2. Towards the close of the last century, the Germans were almost the only successful cultivators of Medical Jurisprudence. The *Elementa* of Plenck appeared in 1781, and the book is still considered a good introduction to the study. The *Bibliothek* of Daniel appeared in 1784; and in it we find the name of *state medicine* given to this branch of knowledge. Between 1790 and 1800, appeared the *Conspectus* of Sikora, the *Handbuch* of Loder, the *System* of Metzger, and the *Entwurf* of Müller.

During the last century little was done in Italy after the time of Ramazzini; and in France the subject had attracted little attention, until the celebrated case of Villeblanche called forth the memoir of Louis on the period of utero-gestation, in which he attacked the pretended instances of protracted pregnancy with powerful arguments, which were seconded by Astruc and Bouvart, but vehemently opposed by Le Bas and Antoine Petit. This controversy gave rise to many able publications, in which Pouteau and Vogel took part; but victory remained with Louis and his adherents.

Louis wrote also a valuable memoir on the anatomical examination of bodies found hanged; he pointed out the mode by which we are able to distinguish assassination from suicide in such circumstances. He applied them to the celebrated cases of Calas, of Syrven, Montbaillet, and Baronet, in which are models of medico-legal investigation; and he may be considered as the first who publicly taught in France the just application of medical knowledge to jurisprudence.

The subject of poisoning was examined by Sallin, in a case where a person had been buried sixty-seven days; and he made a very ingenious attempt to investigate the effects of poisons; but has sometimes substituted speculation for facts.

In 1789 professor Chaussier read his excellent *Memoire* before the Academy of Dijon; in which he shewed the necessity of careful inspection by the medical witness in all cases of death from blows or wounds, and gave admirable models of medico-legal reports. Next year he delivered a course of lectures on Legal Medicine to numerous pupils. The last year but one of the last century gave to the world the very excellent *Traité de Medecine Legale* of Foderé.

It may excite surprise that in this sketch we have made no mention of British authors. The fact is, that with the exception of the short Elements of Medical Jurisprudence published by Dr. Samuel Farr in 1788, which is little else but an abridgement of Fazelius, there was no treatise on Forensic Medicine in the English language.

It is true that some medico-legal questions are ably but incidentally treated in the writings of Mead, Monro, Denman, Percival, and John Hunter, and that an interesting Essay was published by Dr. Wm. Hunter "On the uncertainty of the signs of murder in the case of bastard children;" but the importance of the study, as a whole, was not understood in this country till long after the publication of many valuable systems in Germany, Italy, and France.

In the present century France took the lead. The end of the last century was marked by the institution of three professorships of Forensic Medicine. Mahon was the first French professor, and his reputation as a teacher gave him a name, which the posthumous publication of his lectures has not sustained. The short *Cours de Medicine Legale* of Belloc appeared in 1802. Tartra's excellent Essay on *Poisoning by Nitric Acid* was published in the same year, between which and the year 1810 various short treatises appeared, chiefly on detached branches by Achart, Drouard, Lavort, Masson, Faulaure, Desortieux, Vigné, Lamarre, Banc-Cavé, Godemar, Raffenaut, De Lisle, and Faure.

In 1814 appeared the important *Toxicologie* of Orfila, (a Spaniard naturalized in France), which has changed the face of this part of Medical Jurisprudence, by the number of experiments, the original views on the nature and action of poisons, and the disquisitions on the modes of detecting them, it contains. The French practitioner may consult with advantage the *Manuel* of Bertrand, published in 1817; and the admirable *La Medecine Legale relative à l'art des Accouchemens* of Capuron, has scarcely left us any thing to desire on this branch of the subject. In 1819 appeared the excellent Essays of Lecieux on *Infanticide*, of Renard on *Medico-legal examinations of dead bodies*, of Laisne on *Perforations of the Stomach*, and of Rieux on *Ecchymosis, Suggillation* and *Contusion*, in the same volume. Valuable detached essays by Foderé and Marc are contained in the *Dictionnaire des Sciences Medicales:* and we may close our French list with the *Manuel* of Briand and Brosson, republished in 1828; the *Secours à donner aux Asphyxiées* of Orfila, which appeared in 1833; and the useful *Manuel Complet* of Sedillot.

During the present century Germany has not been idle. We have good compends by Schmidmüller, Masius, and Willberg. Rose published a very valuable essay on *Medico-legal Dissection*, which has been translated and enlarged by Marc, (Paris, 1808); and an excellent treatise on *Pharmaco-chemico-Medical Police*, was given to the world by Remer. This last treatise has been translated into French by Lagrange and Vogel, in 1816. Among many works which have appeared in Germany of later years, connected with our subject, we may mention the curious collection of cases by Von Fuerbach, published in 1828, entitled *Merkwürdiger Verbrechen*—Remarkable Crimes; the little tract of Drs. Bunsen and Berthold, on the power of *Hydrated Peroxide of Iron as an antidote for Arsenic*, which appeared at Göttingen in 1834; the *Contributions to Legal Medicine* of Bernt; and the masterly analysis of various poisons, by Buchner and Herberger.

Only two medico-legal works of any consequence have proceeded from the press of Italy within the present century: the *Instituzione di Medicina Legale*, by Tortosa of Vicenza, and the *Medicina Legale* of Barzellotti.

Medical Jurisprudence may fairly be said to have only commenced in Britain within the present century. The first lectures ever delivered in Britain were given in the University of Edinburgh, in 1801, by the elder Dr. Duncan; and the first established Professorship was conferred by government on his son in 1803, since which period it has been regularly taught in that seminary.

The first original British work on Medical Jurisprudence was Dr Male's *Epitome of Juridical or Forensic Medicine, for the use of Medical Men, Coroners, and Barristers*, which appeared in 1816; and, though a short sketch, it contains interesting notices of English cases, and English law. *Medical Jurisprudence, as it relates to Insanity, according to the Law of England*, was published, in 1818, by Dr Haslam, in a little volume, illustrated by original cases. But the most valuable work then presented to the public, in an English dress, was the *Principles of Forensic Medicine* of Dr Gordon Smith; a volume commendable as an elementary treatise, less diffuse than most of the continental systems, and interesting to the British practitioner, by the numerous references to British cases and to our national codes. In 1820 Dr. William Hutchinson published his useful dissertation *on Infanticide*, in which its relation to physiology and Jurisprudence is very ably considered. These works were soon followed by the more costly publication of Paris and Fonblanque, in three octavo volumes; in which, among some matter little interesting to the general student, are important references to English Jurisprudence.

The last British work we shall mention is the admirable *Toxicology* of Professor Christison, which appeared first in 1829, and has since gone through a second, a third, and a fourth edition; a work the most philosophical and perfect which has yet appeared on the subject of poisons.

It would be improper to pass over the labours of our trans-atlantic brethren in this branch of science. In 1819 Dr Cooper of Philadelphia republished in America the treatises of Farr, Male, and Haslam, with *the remarks* of Mr Dease, intended for the information of juries and young surgeons; a letter originally addressed "to the Chief Justice of Ireland, by a surgeon of that country." Dr Cooper added some notes, and a good digest of the laws relating to insanity and nuisance. Four years afterwards the American press presented us with the excellent work of Dr Beck, which is a compend of all known on the subject. The author has freely availed himself of the writings of his predecessors; but his references to original authorities are copious and correct; and we must consider the last edition as the best work, on the general subject, which has appeared in the English language. We may here also notice the smaller works, *Outlines of Medical Jurisprudence*, by Professor Traill, and the *Manual of Medical Jurisprudence* of Dr Alfred Taylor.

Medical Jurisprudence may be divided into two great branches, *Forensic Medicine*, and *Medical Police*. The first may be conveniently subdivided into, 1st, Questions affecting the civil rights, or social duties of individuals; 2d, Injuries to Property; 3d, Injuries to the person. The second part may also be subdivided into, 1st, Questions affecting the preservation of individuals; 2d, What relates to the health of men collected into communities.

It is obviously impossible, in the limits of a dissertation of this nature, to do much more than allude in general terms to most of the subjects included under these branches.

PART I.—FORENSIC MEDICINE.

SECTION I.—QUESTIONS AFFECTING THE CIVIL OR SOCIAL RIGHTS OF INDIVIDUALS.

Development of the Body.

I.—Development of the Human Frame.—The usual development of the corporeal and mental powers becomes of high importance in establishing personal identity, in determining criminal responsibility, and in giving validity to various civil contracts.

1. *Infancy* is the period from birth until the completion of the seventh year; and its progress is best determined by attention to the size of the body, the evolution of its proportions, and the state of the first teeth. Its conclusion is marked by the loss of the milk incisors, and coming of the first permanent teeth.

2. *Childhood* may be considered as extending from the last period to the 14th or 15th year, or the commencement of puberty. The expansion of the body, the state of the teeth, and of the genitals, are its principal characteristics.

3. *Adolescence* is marked by changes in the whole constitution, by the commencement of the beard in males, and of the catamenia in females; this is of uncertain duration, but may be considered, with us, as extending to the 17th or 18th year.

4. *Youth* is the period between adolescence and the full perfection of the bodily powers. In it the generative function is perfected. We may consider it as terminating with the age of legal majority, though probably it should be extended to the 25th year, as it is with some nations.

5. *Virility* is that period during which all the bodily powers are perfect, and the mental faculties are matured. It has no definite bounds in man; but the perfection of the bodily powers of the female may be considered as bounded by the time when the catamenia cease, or woman is incapable of being a mother. That period is usually about her 45th year. It is during this period that all the bodily and mental faculties have generally acquired their full perfection in both sexes.

6. *Old Age* has no absolute beginning, fixed by nature, except in what we have just noticed of the female. It is exceedingly difficult to ascertain the age of persons of either sex in this period of life, so that no general rule can be fixed, and the limits of old age on either hand cannot be determined. Its general characteristics are stiffness of the limbs, wrinkling of the skin, loss of teeth, blanching of the hair, impaired vision, and decay of all the bodily faculties. Its approaches are often marked by the appearance of fan-like wrinkles at the outer canthus of the eye, by increased obesity, and by the shoulders becoming round.

7. *Decrepitude* is the last stage of human existence, in which the bodily vigour is decayed; the knees and spine are curved, from the inability of the muscles to support the weight of the superior parts of the body, or by alterations in the form of the cartilages; the senses are blunted; and the only refuge is the grave. The periods at which these various changes take place are accelerated and retarded by constitution, climate, food, habits, education, and occupation.

Duration of Life.

II.—Duration of Human Life.—The ordinary chances of human life are an important subject of inquiry, deduced from accurate comparisons of registers of births and deaths. On this is founded the system of annuities, the principles of benefit societies, and of insurances on lives. Unfortunately these registers have been so ill kept in Britain, that our own tables have generally been calculated from foreign registers, especially those of Sweden and Finland. It is well known that Dr Price's calculations, from the Northampton tables, gave far too high a rate of mortality; and have caused much loss to the nation, in the payment of public annuitants. The later tables, calculated from the last Swedish and Carlisle registers, have proved this most decisively; and the labours of Messrs. Milne, Lyon, and Finlaison have since furnished us with surer data for our calculations of probabilities of survivorship, and the payment of benefit clubs. The important questions connected with this subject, and the light which a better system of registration is capable of throwing on many subjects connected with population, and the progress of medical knowledge, the important civil rights of individuals involved in the accuracy of registers of births, marriages, and deaths, has induced the government to take up the whole question of registration, and place it on a public and permanent footing.

Personal Identity.

III.—Personal Identity.—To those little familiar with such inquiries, the danger of mistaking one person for another will not appear very considerable; but the fatal errors which have arisen from this source are too well known in the jurisprudence of every country. It becomes, therefore, of consequence to point out the circumstances by which personal identity may be rendered doubtful, and to indicate the marks by which it is best established. The first may include the effects of age, climate, aliment, habits, passions, wounds, diseases, &c. The circumstances which chiefly enable us to identify one long absent from his native country are, accurate observation of his likeness to his family; his resemblance to what he once was; in some instances his dialect; his recollection of past events; but, above all, the occurrence of scars, or *nævi materni*, known to have been on the individual in question.

Marriage.

IV.—Marriage.—Under this head the principal business of the medical jurist is with the nubile age, according to nature, and legislative enactments; and with physical circumstances affecting the legality of marriages, which may justify divorce.

1. The nubile age, with us, is not below fourteen for the male, and twelve for the female, that being the ordinary period of puberty in our climate; but young persons may after this age be prevented from marrying till the age of majority, by parents and guardians, in England, though this seems doubtful in Scotland.

2. The physical circumstances which may invalidate a marriage are, lunacy in either of the parties at the time, and physical inability to consummate. There are instances of this last being pleaded and sustained in our Courts. Certain diseases, such as epilepsy, are held in some countries to invalidate marriage, but not with us.

Impotence

V.—Impotence and Sterility may arise from,

1. *Functional Causes.*—Of these, habitual intoxication, excessive venery, and diseases which greatly debilitate, or affect the common sensorium, are the chief. They are generally temporary only. In females the same causes may produce sterility; to which may be added excessive leucorrhœa, dysmenorrhœa, anaphrodisia, &c.

2. *The Organic Causes* are malformation of the genitals in both sexes, or total deficiency of some of them. We must be careful, however, not to infer the want of testes,

because none are found in the scrotum. In some individuals they have remained through life in the abdomen, as occurs in the unripe fœtus.

Pregnancy.

VI.—Pregnancy presents a wide field for medico-legal evidence.

1. *The limits* between which it is possible, belong to the province of the medical jurist. It may be limited to the period during which the catamenia recur; but this varies from under ten to more than fifty years of age. A few remarkable instances of impregnation after sixty are recorded; and instances of very early puberty also have occurred, even so early as about four years; but these are exceptions to a general rule, which should be kept in mind, in judging of imputed pregnancy.

2. *The signs* of true pregnancy should be impressed on the mind of the jurist; for he may be called to determine whether a capital sentence is to be suspended on this plea, or whether an accusation of pregnancy may not, from the effect of disease, be made against a virtuous female. It is in the early months that the principal risk of error lies. The usual signs are, the cessation of the catamenia, the darkening of the areola round the nipple, the general state of the breasts, the state of the os uteri, the form of the womb as felt over the pubes; and as the pregnancy advances, the tumefaction of the abdomen, and the motions of the fœtus. At this period, the stethoscope, applied to the abdomen, affords a certain indication. The female, for this last examination, should be in bed, lying on her back, with a sheet drawn smoothly over the abdomen: place the stethoscope between the navel and the pubes, and an attentive ear will readily distinguish two sounds; a *whirring* one, synchronous with the maternal pulse; and the pulsations of the fœtal heart, considerably quicker and of a sharper tone.

3. *Limits of Utero-gestation.* Pregnancy may be protracted beyond nine months, or forty weeks, its usual term; but not so considerably as was once imagined. The Justinian and some modern codes were very indulgent in this respect. Ten kalendar months, or three hundred days, is the extreme limit allowed by the present French code; the Prussian extends it to three hundred and two days, a period sufficient to include every case of protracted pregnancy. The law of England at present has no definite limit; but a case beyond the usual term would go to a jury. The difficulty of any female ascertaining the precise period of her conception is the cause of the discrepant opinions of the physiologists on this subject.

Parturition.

VII. Parturition. This subject is also one of great delicacy, and involves several questions.

1. *Whether it be approaching* in general, may be known by indications described in all books on midwifery. The steps of natural, protracted, and preternatural labour should be familiar.

2. *But the signs of recent delivery* are more important to the jurist. These are, the bruised state of the genitals, relaxation of the vagina and of the uterus, the presence of the lochial discharge, the general appearance of the female, and the formation of milk in her breasts.

3. *The viability* of the child is very important, and is recognized by the perfection of its organs, the position of the *mesial line*, the appearance of its nails, and skin, the cry of the infant, and its capability of sucking. This is a subject of interest; because in some instances, if a child be born *not viable*, it may affect the succession to property, when the mother dies in childbed; and it may bear on certain cases of alleged infanticide. One other question connected with this subject is, when there is a considerable interval between the birth of twins, whether these are to be considered as conceived at the same time. Many deny the possibility of *superfœtation*, which in such cases is contended for by others; but it is a subject involved in much obscurity.

Monsters.

VIII. Monsters and Hermaphrodites. No living human birth, however much it differ from human shape, can be destroyed without committing a capital crime. The law states that *monsters* cannot inherit; but it has left us in the dark, as to what should be considered sufficient deviation from the human form to constitute a monster. *Hermaphrodites* are now considered as beings with malformations of the organs of either sex: and physiology does not admit the existence of true hermaphrodites with duplex perfect organs in the human species.

Paternity.

IX. Paternity and Affiliation become medico-legal questions when a considerable interval has elapsed between the birth of a child and the death or absence of its reputed father: ten kalendar months being the utmost limit to which modern physiology would extend the period of utero-gestation. This subject involves questions respecting children born during a second wedlock of the mother, the circumstances of posthumous children, the laws of bastardy, and the mode of treating alleged cases of suppositious children.

Presumptions of Survivorship.

X. Presumptions of Survivorship.

1. *When a mother and her new-born infant are found dead*, important civil rights depend on the question, which lived the longest; as the husband's right to be *tenant to the curtesy*, or the descent of property derived *from the mother*. The law of England in such cases admits such slender proofs of life in the fœtus as would not be received elsewhere, and leaves much to the evidence of a medical witness. Elsewhere the child must either cry or look around, to constitute a quick birth; but in England a quiver of the lips has been received as a proof of life, in defiance of physiology.

2. *When two or more persons perish by a common accident*, without any but probable means of ascertaining who perished first, as in cases of shipwreck, or on a field of battle, the descent of property may become the subject of dispute. Such questions have been rarely decided in Britain; but probably should be determined on the principles laid down in ancient Roman law, or in the Code-Napoleon.

Mental Alienation.

XI. Mental Alienation. This interesting subject presents a wide field for speculation to the medical jurist.

1. He should be familiar with the four forms of insanity, *Mania, Monomania, Dementia*, and *Amentia*, and be able to indicate the leading symptoms and the most judicious treatment of each. He should be able to detect feigned cases of insanity, and to prevent real lunatics from being treated as criminals.

2. *The chief questions* that may fall under his decision are, how to distinguish the disease, and to prove a man insane; if there be a real lucid interval; what period of life is most liable to insanity; what diseases are most liable to be confounded with it; whether it has increased in these kingdoms.

3. *The nature and management of Lunatic hospitals* are also in his province. It must never be forgotten, that, in such establishments, no more restraint should be employed than is necessary to prevent the unfortunate being from hurting himself or others: while the order and economy of the house is to be maintained by a mild but firm administration; rather like the authority of a parent over children, than the rigid severity of a task-master towards a dependant.

Rights of Deaf and Dumb.

XII. The Rights of the Deaf and Dumb are secured by law; and if the intellect be perfectly sound, there is now no question of their perfect competence to enjoy all the civil rights of other subjects of the state. They can intimate legal consent by signs, or by writing; and should be considered as responsible agents.

Maladies Exempting from Public Duties.

XIII. Maladies Exempting from Public Duties belong to the medical man, both in his civil and military capacity. He may be called to decide whether a man be fit, without imminent injury to his health, or danger to his life, to perform the duties of a juryman, of an officer of justice, or to serve in the navy or the army. In all such cases the certificate of health must be carefully drawn up, on an honest consideration of each case, and a fearless determination to do justice.

Simulated Diseases.

XIV. Simulated Diseases present a field of investigation, requiring caution and discrimination. It may be the duty of the medical man to aid the magistrate in the detection of the guilty impostor, or the military tribunal in consigning to merited punishment the pretended invalid. No questions require more professional skill, more self-possession, or more knowledge of human character.

SECTION II.—INJURIES TO PROPERTY.

Nuisances.

I. Nuisances from Manufactories, &c. These may affect the property of our neighbour in different ways; or the nuisance may be a public one. The first is what is termed a private nuisance, and may be abated by an action for damages; the second is a common or public nuisance, and the proper remedy is by indictment. In certain cases the injunction of a court of equity will stay the nuisance in a summary manner.

It was at one time ruled, "that usefulness shall compensate for noisesomness, and that unless it could be proved *deleterious* to the health, a manufacture, however disagreeable, might be introduced into a town:" but by several later decisions of our judges, it is sufficient to prove that the nuisance complained of is very disagreeable, and renders the property of a neighbour less valuable, or diminishes in a marked degree the comfort of his life. In judging of such cases, a medical man is often on delicate ground, between parties deeply interested in the issue of the cause: but we may in general terms conclude, that what is very disagreeable to the olfactory organs of most persons is injurious to health; and now it is sufficient to prove the very offensive nature of the nuisance, to obtain its abatement or suppression.

The principal nuisances which are likely to become the subjects of an action are:

1. Establishments or manufactures in which offensive odours are either naturally given out, or generated by *putrefaction*,—such as the erection of privies, piggeries, cattle-pens, slaughter-houses, cemeteries, collections of decaying animal and vegetable substances, steeping of hemp and flax, starch making, dealing in various animal matters, as in the trades of the *knacker* and *gut-spinner*.

2. Manufactures which evolve noxious or offensive effluvia by the *aid of heat*,—as in sugar refining, dyeing, glue-making, hartshorn and ivory-black works, Prussian blue making, rendering of fat and tallow, boiling of whale and fish oil, leaf-horn manufactories, varnish making, soap works, acid making, alkali works, preparation of chlorine, smelting houses, coal-gas works, turpentine making, unconsumed smoke from steam-boilers, &c.

3. Manufactures which *corrupt or pollute streams or springs*,—as bleaching, dyeing, tanning, gas making, lime-burning, and the like.

4. Establishments that become nuisances from their *noises*—as the business of the tin-plate worker, the copper-smith, the trunk-maker, the boiler-maker, *tilting* machinery, &c.

Arson.

II. Arson. The crime of wilful fire-raising can rarely become the subject of medico-legal investigation, except when there is a doubt whether the alleged fire may have arisen from spontaneous combustion. Spontaneous combustion may arise in inert matter from

1. *Friction or percussion*, by which the latent heat of bodies is suddenly converted into sensible heat.

2. *By fermentation* of vegetable matter,—as in the firing of new hay, of collections of linen rags, roasted bran, and powdered charcoal; in which the heat excited appears to be owing to the rapid absorption of watery vapour, which, when condensed, gives out its latent caloric in sufficient quantity to cause ignition.

3. *By chemical action*,—as in the effect of drying oils on hemp, flax, cotton, and on some powders,—as that of charcoal, and black oxide of manganese; the action of nitric acid on essential oils, indigo, &c., or the mixture of oil with wool. Under this head also may be advantageously discussed the singular combustions of the human body, which have sometimes led to accusations of murder, when the event was due to spontaneous changes in the living body.

Forgery.

III.—Forgery and Falsification of Documents.—This may be of two kinds:

1. *Forgery of Engraved or Printed Bills.*—The importance of preventing forgeries, in a great commercial country, where public and private bills form an immense portion of the circulating medium, has given rise to various contrivances for the prevention of frauds. This has been attempted by introducing peculiarities in the manufacture of the paper, as the use of *water marks*, and colouring the pulp; but ingenious knaves have imitated both successfully. It has been also attempted by employing complicated designs, not easy of imitation. The most ingenious and successful effort of this kind is the multiplication of the same design, by Mr. Perkins's machinery, through which the *same figure* cut on steel afterwards hardened, may be indefinitely multiplied, by being transferred to copper. The success of this method is proved by the very few forgeries which have taken place on the banks which have employed his plates. Substitution of one sum for another has sometimes been made. This is easiest prevented by the multiplication of the word or figures on the face of the note, and also by care in the manufacture of the printing-ink. It is found that an ink composed of lamp-black, Prussian blue or smalt, with copal varnish, is more difficult of erasure than common printer's ink.

2. *Falsification of Deeds*, and forgeries of names, have been committed by the erasure of the common ink used in the signatures. Common ink is usually effaced by diluted nitric, or oxalic acids, by solutions of chlorine, by caustic alkalis, and by butter of antimony. All these substances soften or injure the texture of the paper, but the traces of this injury have been effaced by washing, sizing, and pressing the paper. If these steps have not been carefully performed, however, the writing may, in some instances, be restored; the erasure by acids, in that case, becomes manifest on the application of an alkali—the effect of alkalis by acids; but chlorine may leave no trace of its employment, except the extreme whiteness of the paper. In deeds and writings of importance the best preventive would be to use as an ink a solution of copal in oil of lavender, coloured by lamp-black. The defect of this ink is, that it is apt to become thick; and, on this account, a solution of gluten of wheat, as the vehicle, has been proposed. (See Ink.)

Coining.

IV.—Coining of False Money.—The care with which the die is prepared will not always secure against frauds of this sort, as the coin itself offers a ready means of obtaining a mould, of sufficient sharpness for the purpose of the coiner. The object of such persons is to pass off base alloys for pieces of gold and silver. These may be detected by deficient specific gravity; but, in the ordinary business of life, this is not a practicable test. Most of the base alloys are much less sonorous than the precious metals, and the sound is therefore employed to ascertain the genuine coin. All coin is alloyed with copper, which imparts hardness, and diminishes loss in *wearing:* this quantity, in our mint, amounts to two parts of alloy for every twenty-two of pure gold or silver, or 1-12th. The simplest method of detecting the intermixture of too large a quantity of alloy is by the change of colour produced when a streak is made on *touchstone*, and compared with the streak formed by needles of metal of ascertained purity; but chemical examination is to be preferred.

1. *Debasement of Gold* is ascertained by dissolving a given weight of the alloy, cut into small pieces, in pure nitric acid. This will leave the gold, but dissolve the baser metals; and the weight of the residue, washed and dried, gives the quantity of gold present. The nature of the alloy may be found by different chemical tests. There is only one debasement of gold coin not to be thus detected. Gold coin has been debased by platinum. If the attempt be made to form an alloy, it spoils the colour of the gold; but at Rouen it was accomplished by plating the platinum with gold so nicely, as to give the piece its due weight. Cutting such a coin will detect the fraud. If an alloy has been made, it may be detected by the colour being greyish, or by dissolving the whole in nitro-muriatic acid; when the addition of muriate of potassa, or of ammonia, to the acid solution, throws down a yellow precipitate, if platinum be present.

2. *Debasement of Silver* is usually detected by *cupellation*. The weight of the button of silver left on the cupel gives the quantity of silver in the alloy. It may also be found by dissolving the alloy in nitric acid, and precipitating the solution by muriate of soda: the precipitate blackens by light, and affords the means of ascertaining the quantity of silver in the compound.

SECT. III.—INJURIES AGAINST THE PERSON.

These may be A, such as do not imply the loss of life; or B, such as usually endanger or destroy life.

A.

Defloration

I.—Defloration.—The signs of defloration are obscure. The state of the sexual organs have been chiefly relied on as indications of the loss of virginity, and in particular the rupture of the hymen; but the hymen has been found entire in some females who have had carnal intercourse with man, and is sometimes naturally wanting, or may be destroyed by disease. The appearance of the nymphæ, and the size of the vaginal orifice, are not certain indications, any more than the appearance of the carunculæ mystiformes, or the firmness of the mammæ. It is only by considering all the signs together, that we can arrive at any just conclusion.

Rape.

II.—Rape.—This crime consists in the forcible knowledge of a woman against her will; her resistance must be continued to the utmost, while she retains her senses or the power of struggling with the ravisher, unless she may have yielded to the immediate fear of death. It is not a *rape*, without these conditions being complete; the woman otherwise is supposed to have consented to the act, which may indeed have commenced in violence, but have terminated with her consent. An *infant*, however, under ten years of age, cannot give legal consent; and whoever has carnal knowledge of such an infant, either with or without her consent, is guilty of a felony. The proofs of rape, besides the consistency of the woman's story, mainly depend on the marks of violence on her person. If a virgin hath been violated, the injury to the sexual organs, with the precautions mentioned under defloration, will be taken into consideration. If a married female be the victim, we must look for bruises on her own person, or injuries she may have inflicted on the ravisher during her resistance, which last are accessory proofs of no small importance. The crime may even be perpetrated on a prostitute. It is rape, if the act be forcible, and against her will. The slightest penetration is sufficient; emission is not now required to be proved. The physical signs of rape soon pass away; and unless the female be inspected within ten days after the alleged violence, we shall, in most cases, vainly seek for confirmation of the allegation from inspection. The charge of rape is not invalidated by the female conceiving, nor by the occurrence of syphilis in the woman.

Mutilation.

III.—Mutilation.—*Demembration*, mutilation of the face, cutting or maiming, were capital crimes by Lord Ellenborough's act; but are not now capital felonies under Lord John Russell's act. The extent of the injury may often be referred to a medical man; and in a case of *slitting the nose*, an English judge overruled the objection of the prisoner's counsel, "that the nose was only *cut*," by stating, "the surgeon sware it was *slit*;" and that slit was anciently synonymous with cut. Castration was always in Britain considered as a capital offence, even when other *mayhems* (as mutilations are termed in English law) were punished by fine and imprisonment. In France, the perpetrator is condemned to hard labour for life, except where it has been "immediately provoked by an outrage against modesty." Castration, long after the infliction, may be recognised by the cicatrix of the wound.

B.

Criminal abortion.

IV.—Criminal Abortion.—The laws of Britain recognise this crime only after the period of *quickening*, on the false idea that then only life enters into the fœtus. Quickening is merely the mechanical escape of the gravid uterus from the pelvis into the abdomen, and usually takes place in the fourth month of utero-gestation. Before this has taken place, causing a woman to abort was not a crime in our code, until the act of 1st of Victoria, where no mention is made of *quickening*, which has nothing to do with the life of the fœtus: and the penalty for causing abortion is transportation for a period not less than fifteen years. The chief means by which abortion is sought to be accomplished are, by blows and bruises on the abdomen, by the administration of drastic purgatives, or other medicines acting violently on the human frame, by repeated venesection, and by the introduction of pointed instruments into the womb. None of the means, except the last, are certain in their operation, but all are highly dangerous to the mother; and one who only essays abortion may thus commit a double murder. In cases of alleged abortion, the medical witness has to consider the involuntary causes which may produce it; as accidental falls and blows, strong mental emotions, errors of diet and regimen, or spasmodic diseases; and he should balance these against the marks of premeditated design.

Infanticide.

V.—Infanticide.—By the laws of Britain, the mother who concealed her pregnancy till she was delivered of a dead child, or who, during labour, failed to cry out for assistance, or whose infant disappeared after birth, was formerly held guilty of infanticide; and many convictions and executions took place on this cruel statute. In later times very moderate proof of these three circumstances was held sufficient to invalidate the capital charge. Even in England, in cases of the murder of bastard children, contrary to all the usual forms of justice, a statute of James I. threw the *onus* of proving her innocence on the mother; and it was not until the 43d year of George III. that this iniquitous law was repealed, and the same rules of evidence here applied as in other cases of murder.

This subject involves some very nice points of legal medicine. The proofs of the child being born alive enter into the case. It must be proved to have arrived at the period when there was a probability of its living; its body should be carefully inspected for marks of wounds or bruises; its cavities should be opened, lest there be traces of injuries sufficient to have caused death, found in the head, abdomen, or chest; the state of the peculiarities in the fœtal circulation, and of the organs of respiration, must be examined; and we must observe whether the lungs seem to have been dilated by breathing, or remain in the dense condition and backward position they have before respiration has commenced. This leads us to consider the celebrated *docimasia pulmonum*, or test by their sinking or floating in water, which was at one time regarded as indisputable proof of the death of the child, before or after birth, but has now been considered as ambiguous. If, however, we try the lungs together with the heart, with that organ separated, each lung separately, and also detached portions of the lungs, we shall generally find little difficulty in deciding the important question, especially if attention be paid to the quantity of blood in the lungs, and the state of the *ductus venosus* and *d. arteriosus*, the contents of the air-tubes, and of the alimentary canal. We must carefully distinguish between the effects of artificial insufflation of the lungs after death, and their floating from respiration, or from incipient putrefaction. In cases of artificial insufflation, the whole lungs will not float, and the air may be squeezed out of a cut portion of the lungs, so as to sink in water; whereas, it is not possible, by compression with the thumb and finger, so to free from air a portion of lung that has respired, that it will not float. Putrefaction may be distinguished by the smell, and the air not being in the cells, but in oblong globules in the cellular tissue uniting the cells.

Infanticide from strangulation, from drowning, and from mephitic air, may be distinguished by the marks to be mentioned under *asphyxia*. Infanticide may be produced by *omission*, as by neglecting to tie the navel string; in which case the body will appear bloodless, the great vessels near the heart, and that organ itself will be empty. The child may perish, if not removed from the discharges which accompany delivery; and the possibility of this happening, without any fault of the mother, must be taken into consideration. The infant may die from exposure to cold. If it be found in a remote or sequestered situation, that would be ground for suspicion. If there be meconium discharged from its bowels; if it exhibit marks of starvation, in the emptiness of its alimentary canal; or if it appear to have been fed, we may be sure that it was born alive, and probably perished from criminal neglect. Any artificial objects, such as articles of dress, found near the child, should be carefully preserved, as one means of identifying the exposer; and if foot-marks are seen there, they should be accurately measured and noted.

In cases of exposed infants, it is very important to ascertain the real mother. As such exposure usually takes place soon after birth, comparing the age of the infant with the signs of recent delivery on the suspected mother, is the best method of proving the connection between them.

Homicide.

VI.—Homicide.—It is only with culpable homicide, and with murder, that the medical jurist has to deal. When a person is found apparently dead, a medical man may be required to inspect and report on the cause of death. He should, of course, first ascertain whether it be a case of real or only of apparent death. This sometimes is not easy. Singular instances of resuscitation from apparent death are noticed by Winslow, Bruhier, and others, which should make us pause ere we hastily pronounce a person dead, without evident causes for his death appearing on his body. Neither pallor of the face and lips, insensibility to stimuli, cessation of the organs of respiration and circulation, loss of heat, nor even stiffness of the limbs, are infallible criteria. Until, along with these, we have marks of incipient putrefaction or decomposition, we cannot be absolutely certain that a person is quite dead; and, in all cases of doubt, we should wait for incipient putrefaction ere we sanction interment. Where the symptoms appear at all equivocal, we should scarify, or apply hot oil to some parts of the skin.

Here it may be proper to describe the general method of carrying on the *medico-legal* examination of a body.

In cases where a person is found dead, the body should be carefully inspected for external wounds or marks of contusions. Any wound, however minute, should be traced with a probe, and followed to its termination by the knife. Blackish marks should be cut into, in order to ascertain whether they be the effect of the effusion of coagulated blood, or merely the consequences of that infiltration of the skin which takes place in the depending parts of bodies after death. The first is termed *ecchymosis;* the latter may be distinguished from the former by the name of *sugillation.* In the subsequent examination of the head, the hair should be removed, the scalp inspected, and afterwards divided from ear to ear, over the vertex; the skull-cap removed; the state of the brain and its membranes carefully marked, and especially any unusual appearances noted down. All should, on the spot, be committed to writing —nothing trusted to the memory, however tenacious. The inspection of the larynx, trachea, and gullet, is best performed by making a cut through the lower lip, and down the fore part of the neck and chest, to the xiphoid cartilage. Transverse cuts should then be extended from the longitudinal one, along the edges of the lower jaw and the collar bones, so as to enable us to turn back the integuments of the neck. The symphysis of the chin should then be sawed through, and the soft parts divided. We can thus separate the two sides of the lower jaw. When the tongue is pulled forward, the fauces, and upper part of the œsophagus and larynx, are freely exposed, and the introduction of acrid poisons, or of foreign bodies, may often be thus detected. The state of the cartilages of the larynx and trachea should be noted, as fracture or displacement of these has occasionally detected strangulation. A ligature should be put on the lower part of the gullet, and the tube divided above the ligature.

The abdomen may next be opened, by a cut through the skin from the sternum to the pubes. In new-born infants the whole skin and abdominal muscles may at once be cut through, along the cartilages of the ribs on each side, and thence to the anterior edge of the ileum, curving downward to the pubes. This will, when the flap thus formed is turned down, expose the abdominal viscera sufficiently, without disturbing the vessels of the umbilical cord. In the adult, we may first separate the skin of the abdomen from the muscles, in one line from the sternum to the pubes, and, as it is easily extensile, cut out a flap of the muscles of the abdomen, as above directed, so as to expose the viscera. The skin so divided makes a neater appearance when sewed up, than when the muscles and skin are divided together, as in the infant. A ligature should be put on the duodenum, and division of the intestines made below the ligature; so that we may remove the stomach and its contents, and reserve them for subsequent examination. The other viscera should also be carefully inspected. The thorax should be last examined; because this enables us the better to ascertain the descent of the diaphragm, and the arching of the chest, which takes place in asphyxia, than when we open the chest before the abdomen. The cartilages of the ribs should be divided as close as possible to the ends of the ribs, as thus a larger opening is made in the chest. The position and appearance of the lungs and heart should be noted, and their engorgement with blood, or the emptiness of the great vessels, ascertained. When it is necessary to examine the spinal canal, the body must be laid on a table with the face downwards: an incision is to be made along the whole spine, from the occiput to the sacrum, the integuments are to be separated on each side, so as to expose the posterior portion of the vertebræ, which may be divided near the transverse processes by a saw, the *rachitome*, or by cutting plyers. A triangular piece should also be sawed out of the occipital bone at the foramen magnum. This will expose the whole spinal canal.

Homicide may be accomplished by several modes that may sometimes be ascertained by examination of the body.

Death from Suffocation

Death by *Asphyxia* or suffocation may be produced by drowning, by hanging, by strangulation, and by mephitic air.

1. *Drowning* may produce the fatal effect in two different modes. In some the suddenness of the shock, or the surprise instantaneously arrests both the functions of circulation and of respiration; no struggle precedes death. This species of drowning has been justly compared to syncope; and hence has been by Desgranges termed *asphyxia syncopalis.* In others the circulation goes on for some time after the respiration has been interrupted; the animal struggles, makes vain efforts at inspiration, and portions of air are forced out of the lungs by a convulsive effort of the muscles of respiration. The circulation of unoxygenated blood through the brain seems to act as poison on that delicate organ; and the consequence is diminution of nervous energy over all the body, by which the play of the heart is enfeebled and the animal soon dies. In this case the brain is usually found congested with dark blood. This state has been aptly termed *aphyxia congestiva.* This difference in the phenomena may account for the great difference perceived in the bodies of drowned persons, and also for the difference in the chances of recovery after submersion. In the first species the pallor of the countenance is marked, and the features little altered. In the latter, the face will often appear swelled and livid, the tongue be protruded, the nose and air passages filled with frothy mucous, the brain and right side of the heart gorged with black blood. The body which has been sometime immersed is generally pale, the eyes are half open, and the pupils generally much dilated, the chest arched, and the diaphragm pushed down into the abdomen. These last signs are most conspicuous in those who have perished from *asphyxia congestiva.* When the person has retained his sensibility after falling into the water, the ends of the fingers are often found excoriated by his grasping at any object within his reach; and mud or gravel will often be found lodged below his nails. The blood in drowned persons generally remains fluid. These are the principal signs by which we can distinguish the extinction of life by drowning, from the cases in which the person has been thrown into the water after death. If we find in the stomach water containing any foreign bodies, such as fragments of straws or weeds, similar to those in the water in which the body was found, we may be sure that the person was living when immersed in the water: for no water will enter the stomach after death.

It may, however, be very difficult to distinguish a murder by drowning, from death by accidentally falling into water, or from a suicide. The most material circumstances will be, the marks of struggle near the spot where the body has been immersed, the obstacles in the way, the impressions of the feet of more than one person leading to the water. We must also pay attention to appearances of injuries on the body, which could not have occurred from simply falling into the water; such as marks of strangulation on the neck, or wounds inflicted by deadly instruments.

2. *Hanging* produces most of the internal appearances just described; such as turgescence of the vessels of the head, livor of the face, fluid black blood in the lungs and right side of the heart, protrusion of the tongue, and the nose loaded with mucus: but besides these, we usually find a mark round the neck; and when the person has undergone a public execution, especially when the *drop* is employed, there is often luxation of the neck, and fracture of the *processus dentatus.* Ecchymosis is generally found under the mark of the rope: sometimes this mark is not apparent until some hours after death, but dissection will shew the cellular tissue, beneath the rope, dry and compressed. The face is generally less distorted, the eyes less prominent, in those in whom luxation of the neck is produced by the drop, than when the struggle is more protracted. Recovery is hopeless in the first case, but has sometimes followed the asphyxia produced by mere strangulation, which seems to cause a stupor, that is, however, soon fatal, if the person be not soon relieved.

In examining the body of a person found suspended by the neck, we must determine whether this be really the mode in which life was extinguished, or whether the body was suspended after death. The absence of the usual marks of hanging, the position of the rope-mark on the neck, the presence of other mortal injuries, the appearance of the rope are all important objects of consideration. These become of the utmost importance in the difficult cases, where there is a doubt whether the person was murdered or committed suicide. We must rely for a solution of the problem on the indications just noticed, and the previous history of the individual.

3. *Strangling* may be accomplished by drawing a rope tightly round the neck, or by forcibly compressing the anterior of the windpipe, after the manner of Burke and his imitators. In the first, the mark round the neck will generally be nearly circular and not inclined to the ear or occiput. In the latter, marks of fingers will often be perceived on the neck, or a circular depression will be found on the front of the windpipe, and sometimes some of its cartilaginous rings will be broken or displaced. The signs of suffocation will be equally present, as in hanging; but if the mark of the cord be on the *lower* part of the neck, it cannot be a case of death by hanging.

Suffocation has sometimes occured from bulky substances sticking in the gullet, and compressing the trachea. Assassination has also been effected on infants, or on feeble individuals, by covering up the mouth and nose. This last mode leaves no external marks of violence, and can scarcely be detected, except by the appearances of suffocation found after death.

4. *Mephitism*, or death from irrespirable gases, often happens accidentally, but is seldom the mode of assassinaation, except in cases of infanticide: and will be noticed under Toxicology.

In every case of suffocation our attempts at reanimation should be directed to renew respiration by inflation of the lungs, to restore the animal heat by exposure to warm pure air, and by assiduous frictions of the surface, to rouse by stimuli, and by brushing the soles of the feet and palms of the hands, to relieve cerebral congestion, when necessary, by moderate and cautious bleeding.

Death from Starvation.

VII. Death from Starvation. Cases may occur where it is important to distinguish this from other modes of the extinction of life. In such cases the cutaneous veins disappear, the skin has become harsh and has a shrivelled look; the fat has disappeared, and the soft parts are mostly wasted; the gums desert the teeth; the eyes are commonly more or less open and bloodshot; the tongue and fauces are dark and dry; the stomach shrunk, blackish and ulcerated on its internal surface; the intestines resemble a cord; the gall bladder is gorged with bile, which stains the intestines to a considerable extent; the heart is wasted, and the great vessels are almost empty; the body exhales a most offensive odour of putridity, even before life is extinct.

The period required to destroy life in inanition is very various, and appears to be shorter in the young and vigorous than in persons of middle life, in men than in women. In some comatose diseases, and in persons reduced by previous illness, the life under inanition has occasionally been greatly protracted; and when there has been stupor with occasional intermissions, an astonishingly small quantity of liquid aliment has prolonged life for many weeks, months, or even years. Some of the published cases of *fasting* are apocryphal; but in others where the quantity of nutriment has been extremely small, the individuals may be considered as in the state of hybernating animals, where the diminished nervous energy renders the waste of the system exceedingly slow. Those who are deprived also of drink perish soonest of inanition; and those who are confined in dry warm air, than those exposed to a moist, cool atmosphere.

Death from extremes of Temperature.

VIII. Death from Extremes of Temperature.

1. *From extremes of cold.* After the sensation of tingling in the fingers and toes, exposure to extreme cold is soon followed by languor, loss of sensation, and irresistible propensity to sleep, which is so oppressive, that even the known fatality of the indulgence while exposed to the cold is insufficient to prevent the sufferer to seek repose. Cold does not seem to produce a painful death. In arctic regions the best preservatives against extreme cold are, woollen garments next the skin, with furs and dressed leather over them, a free use of warm diluents, and avoiding wine and spirits.

2. *From a much increased temperature*, the fatal effects may be *scalding* or *burning*, according to the medium applied. This mode of extinction of life leaves very obvious traces on the body. Sometimes fire has been applied to the body after death, to conceal a murder. This fact suggests the propriety of the medical man examining a scorched body minutely, lest there be wounds on its surface, inflicted during life. If the person has lived sometime after the scorching, in general there will be found a ring of inflammation surrounding the eschars: but this only takes place when the burning has not been so severe as to sink the powers of life beyond the capability of reaction.

An increased temperature may be insufficient to vesicate or destroy the skin, yet may prove fatal; as is well known in what is termed a *coup de soleil.* This is a species of apoplexy, chiefly induced by the direct influence of the sun on the head, and appears to be similar to the effect of the *Khamsin* or *Simoon* of the desert.

3. *Death from lightning* is not wholly to be attributed to the high temperature, but partly to the impulse or shock instantly affecting the brain, and paralyzing the heart: yet as the marks of singeing are often observed on the bodies of those killed by lightning, it may be here considered. The skin is sometimes discoloured in stripes or oblong patches; at other times the surface has no mark of injury, but the viscera have been observed more or less affected, and occasionally there is a small perforation on the skin. The blood is described in every case as remaining fluid, and the corpse runs rapidly to putrefaction.

Wounds.

IX. Wounds. The examination of wounds, whether fatal or not, often becomes an important branch of legal medicine. Wounds are usually divided into contusions, lacerations, incisions, stabs, gunshot and poisoned wounds. Each kind requires to be minutely examined, and described, as they are in approved works on surgery. The degree of danger from each should be familiar to the jurist; and he should recollect that there is scarcely any wound which may not become *incidentally* fatal from improper treatment, or peculiarities in constitution. Punctured wounds or stabs require minute attention; for there have been instances in which death has been produced by an instrument not thicker than a pin, thrust into the brain, the spinal marrow, or the heart.

Poisoned wounds belong to Toxicology.

Wounds are more or less dangerous according to their locality.

1. *Wounds of the head* are always dangerous, especially if the blow has been considerable. The person so wounded may die without separation of the integuments or fracture of the bone; as happens in what is termed *concussion* of the brain. Contusions which do not divide the skin may fracture the skull; or the inner table of the skull may be fractured without the outer being broken or depressed. Even wounds of the integuments may prove fatal, from inflammation extending inwards to the brain. Punctured wounds of the head are more dangerous than cuts, as more likely to excite fatal inflammation. When the brain or its meninges are injured, all such wounds are generally fatal.

Wounds of the face or organs of sense are often dangerous, and always disfiguring. Malicious disfiguring of the face was made a capital felony in the reign of Charles II., by the *Coventry act;* but the monstrous anomaly pointed out by Filangieri, that disfiguring *with the intent to disfigure* was punished with death, while *the intent to murder* was not capital, no longer disgraces our statute book. Wounds of any of the organs of sense are generally dangerous, and always produce serious inconvenience.

2. *Wounds of the neck* are always very serious wherever more than the integument is divided. The danger of opening large blood-vessels, or injuring important nerves, is imminent: even the division of a considerable vein in the neck has proved immediately fatal, from the entrance of air into the vessel, and its speedy conveyance to the heart. A blow on the side of the neck has instantly proved fatal, either from the blood being forced back into the brain, or from injury to the superior parts of the par vagum, the great sympathetic, or the other cervical nerves. Dislocations and fractures of the bones of the neck prove instantly fatal.

3. *Wounds of the Chest* are always serious, when the cavity is penetrated, though persons have recovered from wounds of the lungs, and have even survived for some time considerable wounds of the heart. This last is an important fact; because we are not always to consider the spot where the body of a person killed by a wound of the heart, and apparently remaining where he fell, is found, as that in which the death-wound was inflicted. Instances have occurred of persons surviving severe wounds of the heart for several days. Fractured ribs are never without danger; and the same may be said of severe contusions of the chest, from the chance of inflammation extending inwards. Wounds penetrating both sides of the chest are generally considered as fatal, though animals have recovered after having both sides of the thorax penetrated, and the wounds kept open for some minutes.

4. *Wounds of the Abdomen*, when they do not completely penetrate, may be considered as simple wounds, unless when inflicted with great force, so as to bruise the contents of the cavity; in that case, they may produce death without breach of surface, as sometimes happens from blows or kicks on the belly. Wounds injuring the general peritonæum, or that duplicature of it investing the stomach and intestines, are highly perilous, from the risk of severe inflammation. Wounds of the stomach or intestines, or of the gall bladder, generally prove mortal, from the effusion of their contents into the general cavity producing fatal inflammation. Wounds of the liver, spleen, or kidneys, are generally soon mortal, from the great vascularity of those organs.

5. *Wounds of the Extremities*, when fatal, may generally be considered so from excessive hæmorrhage, from the consequences of inflammation and gangrene, or from the shock to the system, when large portions of the limb are forcibly removed, as in accidents from machinery, and in wounds from fire-arms.

X.—Toxicology.—This most important branch of legal medicine has been more thoroughly investigated than any other part of Medical Jurisprudence. A poison may be defined *a substance capable of impairing or extinguishing the vital functions, in a great majority of cases.* This limitation is necessary, because some of the most deadly substances, in small doses, may be taken not only with impunity, but with salutary effects; and habit renders doses of them innocuous, which would destroy an individual unaccustomed to their use. Some poisons act directly on the organs to which they are applied; others appear to act by their influence on the nervous system. Some appear to act merely as irritants or escharotics; others by directly impairing vital functions; and some have a twofold action. The manner in which poisons affect the system appears to be either through their direct influence on the extremities of the nerves to which they are applied, or by absorption, and consequently by the circulating fluids. The rapidity with which some poisons, as hydrocyanic acid, act, favours the opinion that their influence is instantaneously conveyed to the vital organs by nervous communication. The detection of poisons, in some instances, in the blood, or in the exhalations or secretions, favours the opinion of the circulation being one channel by which they are carried to the system; a fact which is further confirmed, by the effect of ligature, or of division of vessels, in preventing the constitutional affection of the poison on the system. Some poisons exert their deleterious influence on one organ, or set of organs; others generally affect the system. Poisons, classed according to their effects, may be divided into *irritants, narcotics, narcotico-acrids*, and *septics*. Their action is modified by the tissue to which they are applied, the constitution of the individual, the quantity of the poison, and its mechanical state.

The mode of treatment of poisoned persons depends on the nature of the poison. The first indication is undoubtedly to evacuate the poison as speedily as possible, by the stomach-pump or by emetics; the second, to administer antidotes, if any such be known for the particular poison; the third, to shield the stomach and *primæ viæ* against the acrimony of the substance; and, lastly, to obviate any violent or untoward symptoms they may produce, by all the resources of our art.

The evidence of poisoning may be presumptive, or positive, physical, or moral. The physical proofs are derived from the symptoms, from experiments on the lower animals, and from a chemical investigation of the *ingesta* or *egesta*. The symptoms, however, only supply us with probable evidence; but the most important inferences they afford are deduced from the simultaneous occurrence of similar symptoms, in more than one individual previously in good health, soon after a meal on the same articles of diet. Experiments on the lower animals with the remains of the ingesta, or portions of egesta, are not much to be relied on, as all animals are not equally susceptible of the same poisons; and what is deleterious to one is innocuous to another. Some poisons, however, such as arsenic and corrosive sublimate, are equally poisonous to all. Such experiments we consider as scarcely justifiable, except in the cases of some vegetable poisons, which cannot otherwise be readily detected. The evidence from chemical analysis of the stomach, of the ingesta or of the egesta, is the most unexceptionable. The refinements of modern chemistry have enabled us to detect surprisingly minute quantities of inorganic poisons, and even of some vegetable poisons. In such investigations, the contents of the stomach, or egesta, should be put into clean vessels; if too thick, diluted with distilled water, boiled, and when cold, filtered through muslin, and then through paper. If the filtered liquor contain much animal matter, this must be separated, as it obscures the various tests to be applied. This in general is best done by acidulating the liquor with vinegar, by again boiling and filtering. Sometimes it requires to be further clarified, by the addition of animal charcoal, or of nitrate of silver, which separate all the animal or vegetable matter. To portions of the clear and colourless liquid thus obtained various tests are applied, the effects of which will decide the nature of the poison. Sometimes the whole poison may have been so evacuated by vomiting, or taken up by absorption, that not a trace remains in the contents of the stomach. In this case we can occasionally detect it, by cutting the stomach into pieces, boiling them in distilled water, purifying the liquid by some of the processes already described, and then applying the tests. Narcotic poisons are easiest detected by their smell; sometimes we can eliminate one or more of their peculiar ingredients by chemical means, but frequently we have no better means of detecting them than by the symptoms they produce, and the moral evidence of the case, or the morbid appearances on the body after death.

We are not to regard the livid appearance of the body as evidence of poisoning; it is not always present in cases of poisoning, and may arise from other causes. The rapid putrefaction of the body is as fallacious an indication. The very reverse is sometimes the fact. The classes of irritant and narcotico-acrid poisons are usually indicated by inflammatory appearances in the primæ viæ, but these are not invariably present; and cases often occur of which the moral evidence may be strong, yet the direct evidence may amount to no more than a probability.

The moral evidence of poisoning may sometimes be best collected by the medical attendant. He may be the only witness to the conduct of the accused; he may have observed him suspiciously active in removing every trace of the potion administered, or of the egesta in which a poison might be detected; he may have observed the guilty confusion of the suspected person, or heard his attempts to explain a fatal mistake, if the administration has been traced to him; or the physician may have been the chief depositary of the dying declaration of the sufferer. All these things it is his duty to note down, and to transmit to the proper authorities.

Poisons are derived from the inorganic or organic kingdoms of nature. The first class may be metallic, earthy, alkaline, and simple chemical substances, and gaseous bodies: the second vegetable and animal poisons.

Metallic Poisons.

i.—Metallic Poisons.—Of these arsenic, quicksilver, copper, lead, antimony, zinc, tin, bismuth, chrome, silver, gold, are the most important.

1. *Arsenic* is poisonous in all its combinations. Its most usual preparations given as poisons are, the blackish oxide or fly powder, the white oxide or arsenious acid, the sulphurets, and the combination of arsenious and arsenic acids with alkalis. All are very deadly, even in small doses, whether swallowed, introduced into the anus or the vagina, applied to the abraded surface, or even when extensively applied to the whole skin. The symptoms commence usually within an hour after the administration; and are, nausea, vomiting, great heat and pain in the stomach, purging, intense thirst, severe spasms in the limbs and body, prostration of strength, pallor of the face, a feeble pulse; sometimes convulsions precede death. In a few cases the symptoms of an irritant poison are wanting, and the arsenic appears to be fatal by immediately inducing paralysis of the heart.

The fauces, gullet, and stomach are often found marked by inflamed patches of a deep vinaceous colour, produced by blood effused under the villous coat of the stomach. Sometimes the villous coat appears corroded or thickened, but the stomach is seldom perforated. When the villous coat has suffered erosion, the poison has generally been given in the solid form, and grains of it may often be picked off the surface of the stomach for analysis. The inflammation seldom reaches to the jejunum; but, though the greatest portion of the small intestines and the colon escape, marks of irritation are often observed about the rectum, especially if the purging has been violent. Various antidotes have been proposed, such as charcoal and magnesia; but the only substance that seems to deserve any reputation is the recently prepared *hydrated peroxide of iron*, promptly administered in large doses.

The means of detection, when the arsenic is solid, are easy. Introducing it, with charcoal powder if it be white arsenic, or with black flux if it be orpiment, into a small tube, and applying gradually the heat of a spirit lamp, will afford a blackish, shining, metallic crust, the interior of which is crystalline. A portion of this, exposed to heat, exhales as a white smoke, and gives out an alliaceous odour. Another portion, slowly heated in a tube open at both ends, is converted into minute tetrahedral crystals. When it exists in solution in the contents of the stomach, we have to clarify the liquid, by the means already mentioned, and to apply tests; of which the most approved is a stream of sulphuretted hydrogen, which throws down a lively yellow precipitate; the ammoniaco-nitrate of silver, which gives a yellow precipitate, that soon fades to a brown; ammoniaco-sulphate of copper, which gives a green precipitate. Either of these precipitates heated with black or soda flux, in a glass tube, will afford the crust already described. These indications leave no doubt of the presence of arsenic; and from the $\frac{1}{200}$ or $\frac{1}{300}$ of a grain may be converted into a sensible metallic crust. Arsenic seems to have a tendency to preserve from putrefaction the stomachs of persons poisoned by it; and it has been detected in bodies that have been from four months to two years buried.

2. *Mercury or Quicksilver.*—This metal in its pure state has been supposed innocent; but when in the state of vapour it is well known to be speedily deleterious, and to produce all the symptoms of mercurial poison. The most usual mercurial poisons are corrosive sublimate, or bichloride of mercury, its oxides, and sub-salts. The long-continued use of calomel is capable also of acting as a poison; but almost the only mercurial poison criminally administered is corrosive sublimate, though, from its detestable taste, it cannot be given by the mouth as a secret poison.

The usual indications are a styptic taste, then burning of the throat, violent vomiting, great distress in the stomach and bowels, violent cholic and severe purging, blood mingled with the matter brought up by vomiting, or ejected by stool. The symptoms often simulate dysentery: the face at first is often flushed, the eyes sparkling; soon the powers of life sink, the voice is lost, cold clammy sweats bedew the surface, perception of external objects is lost, and convulsions close the scene. When the substance is given in small doses, or if the mercurial be a milder preparation, after dysenteric symptoms ptyalism supervenes; the person may sink from the violence of that affection, the fauces may become ulcerated, and gangrene may ensue. If ptyalism follow the administration of a single large dose of mercurial, it is always to be regarded as a formidable symptom. When the person survives, he may suffer from mercurial palsy.

The effects of mercurial poisons are indicated after death by the following appearances. The fauces are generally more affected than from arsenic, and the inflammatory appearances are more diffused over the alimentary canal. Destruction of the coats of the stomach are often observed, either the consequence of the escharotic power of corrosive sublimate, or of ulceration. Peritonæal inflammation is not uncommon; and irritation of the urinary organs, perceived during life, is marked by inflammatory indications found after death.

We possess in whites of eggs, milk, and gluten of wheat, very effectual antidotes for the poison of corrosive sublimate, provided they be given soon after the poison. The first is the most powerful. The secondary symptoms must be met by antiphlogistic remedies and venesection.

Mercurial poisons are easily detected when we obtain them in substance, but not so readily when mingled with the contents of the stomach. Corrosive sublimate is readily decomposed by several animal substances, and therefore we are not likely to detect it unchanged in the contents of the stomach. It is there usually converted into calomel, either in whole or in part. When held in solution, it is easily detected by Sylvester's method, *i.e.* by dropping a little of the suspected liquid, slightly acidulated, on a gold plate, or a gilt card, and touching the gold surface, through the liquid, with a piece of zinc or iron wire. Professor Traill employs a similar method to separate the whole mercury from its solution. He wraps a gold leaf round a slip of zinc, and immerses it in the suspected liquor, slightly acidulated—the mercury is precipitated; and scraping off the gold and the tarnished surface of the zinc, he introduces them into a small tube, and the heat of a spirit lamp is sufficient to produce a ring of brilliant metallic globules. He has employed a similar method to separate arsenic from its solutions.

In all probability the mercurial will not be found in the stomach in a soluble state. In this case we have to form the contents of the stomach into a pulp, and to pass a stream of chlorine through the mass, when the mercurial present will be converted into bichloride, which may be separated by filtration; drive off the excess of chlorine by boiling the liquid, and then either precipitate the mercury, by introducing into the liquid a cylinder of pure tin, according to Devergie's method, or by Traill's combination of zinc and gold leaf. The tarnished surface of the metals in either case is to be scraped, and the powder so obtained introduced into the tube and heated, as already described.*

When we have much corrosive sublimate to operate on, we may try it by lime water, which throws it down of a deep yellow; by alkalis, which form with it an orange precipitate; by protomuriate of tin, which gives a slate-grey powder; and by hydriodate of potassa, which forms a splendid scarlet precipitate.

3. *Copper.*—The poisonous effects of the salts of copper have long been known; but though little likely to be used as secret poisons, they sometimes produce death from being accidentally mingled with food, as in the use of culinary utensils of copper. The symptoms are those of other irritant poisons, to which is added spasmodic rigidity of the limbs, in some cases amounting almost to tetanus. Salts of copper may produce salivation, and also jaundice. The morbid appearances are not very characteristic.

Albumen of eggs appears an antidote of some power against the salts of copper, and therefore, after evacuating the stomach, the whites of raw eggs should be administered. Inflammation should be obviated by antiphlogistic means.

The poison of copper may be sought for by boiling the contents of the stomach with acetic acid; this will dissolve every preparation of copper, and enable us to separate them from animal and vegetable matter by the filter. We may, if necessary, concentrate the solution by evaporation; and if the addition of ammonia give the solution a blue colour, we may be satisfied that it contains copper. A stream of sulphuretted hydrogen throws down a brown precipitate from the solution of copper; and if the quantity of copper be considerable, a piece of bright polished iron will become coated with a film of copper.

4. *Lead.*—The poison of lead is of considerable consequence, although never used as a secret instrument of revenge. Its oxides and salts all appear to be deleterious, but those from which accidents have most commonly happened are litharge, white lead, and sugar of lead. These

often find their way into the stomach, from little-suspected sources, and produce a species of poisoning with very peculiar symptoms. Leaden pipes and cisterns are acted on by water, especially by soft rain-water, and the carbonate of lead thus formed being soluble in an excess of carbonic acid, is liable to enter the human system with the food. Acescent articles of diet act on leaden vessels, and, when aided by heat, on the plumbiferous glazes of our earthenware. These are the most general sources of this poison; but persons engaged in works where white lead is largely used, smelters of lead ores, painters, and potters, are liable to the same deleterious influence. The symptoms produced are obstinate constipation, severe tormina, with the symptoms commonly known by the name of *painter's colic, colic of Poitou*, and of *Devonshire*. After these have subsisted for some time, the person begins to have paralysis of the limbs, first of one or both arms; in general the extensor muscles suffer before the flexors, and the palsy may then become general in that limb, or extend to other parts. The preparations of lead, when given in large doses, appear to act as irritant poisons.

Orfila found that animals poisoned by sugar of lead had a preternatural whiteness of the villous coat of the stomach, if they perished speedily; but, if their death were protracted, the inner coat of the stomach was reddened. The stomach has often been found corrugated after death.

Frequent ablution of the surface is the best prophylactic for those much exposed to the powder of the preparations of lead; and when lead has been introduced into the system with the food, the best means of obviating the return of the evil is by rigidly excluding lead from all culinary and economic purposes. Hard water is less liable to act on lead than soft water, and hence the impropriety of lead cisterns for rain water. Mercury seems to have a beneficial effect in lead colic, especially when conjoined with opium.

Lead is easily detected. To whatever articles it is suspected to enter add vinegar, and boil; filter the solution and all the lead will be in the clear liquor. If in large quantity, it may be detected by the sweetish astringent taste of the liquid; part of which may be tried by the addition of a solution of sulphuretted hydrogen, or of hydrosulphuret of ammonia, which instantly darkens the most dilute solution of lead; another portion may be tried by bichromate of potassa, which throws down solutions of lead of a brilliant yellow; a similar colour is formed with them and hydriodate of potassa.

5. *Antimony* is rarely a poison; because its most active and best known preparations are violently emetic, and thus counteract its effects. Emetic tartar, when given to the lower animals, if vomiting be prevented by tying the gullet, causes inflammation of the lungs and stomach; and this would probably be its effects on man. The lungs appeared a mixture of orange-red, and violet-blue, and they were gorged with blood, which prevented the usual crepitus. It was also fatal when applied to a wound. The stomach was violet coloured, thickened, and covered with tough mucus, the intestines empty, in a man killed by emetic tartar.

The best antidote for this poison is decoction of peruvian bark, especially of *cinchona cordifolia*.

The detection is not difficult: sulphuretted hydrogen throws down a rich orange-red precipitate. When the antimony is mixed with animal and vegetable matter, add first a little muriatic acid to precipitate the contaminating substances, and then tartaric acid to dissolve any antimonial present. This will afford by filtration a clear liquid for the application of the tests. The sulphuret is best reduced by Dr. Turner's process; *i. e.* passing a stream of hydrogen over it when heated to redness in a tube.

6. *The other metals*, though affording some poisonous salts, scarcely require notice in this place. *Zinc* in solution may be detected by a stream of sulphureted hydrogen affording a whitish precipitate. *The muriate of tin* affords one of a rich purple, the powder of Cassius, with deuto-muriate of gold; and when strong, coagulates milk completely. *Sub-nitrate of bismuth* may be detected by calcining in a moderate heat the contents of the stomach, and adding diluted nitric acid to form a solution, from which water throws down a white precipitate. The soluble *salts of silver* are thrown down by alkaline and earthy muriates; and the precipitate is easily fusible into *horn-silver*. A plate of copper becomes silvered by immersion in the solution of silver. *Gold* may be detected by solution in nitro-muriatic acid; which solution affords the purple powder of Cassius with muriate of tin; and the neutral solutions of gold instantly gild silver or copper immersed in them.

Earthy and Alkaline Poisons.

II. EARTHY AND ALKALINE POISONS.

1. *Baryta.*—Both the carbonate and pure baryta are very poisonous, as are the soluble salts of this earth. The symptoms are those of irritant poisons: the senses then become blunted, the respiration feeble, and convulsions close the scene. The stomach is found inflamed, and the brain shews congestive apoplexy. The antidotes are any of the alkaline sulphates, which instantly form with all the poisonous salts of baryta, insoluble, inert compounds. Sulphuric acid, or sulphates, are also the tests of this earth: but it might be confounded with strontia, the salts of which do not seem poisonous, except in as far as they are acrid. The best distinction is obtained by procuring a muriate of the suspected salt, and dissolving it in alcohol. The muriate of baryta imparts a yellow colour to the flame of spirit; the muriate of strontia, a fine red.

2. *Lime* is only poisonous as an acrid. The antidotes for it are phosphates of soda or potassa, and water impregnated with carbonic acid. The detection of the salts of lime is easy. Its properties when pure are alkaline: it forms with sulphuric acid a substance of little solubility; but phosphoric and oxalic acids precipitate it from all its soluble combinations.

3. *Potassa* and *Soda.*—The pure alkalis and their carbonates are poisonous. Several fatal accidents have happened from them. They act as strong irritant poisons, producing intense heat and pain in the abdomen, then cold sweats, tremors, and convulsive twitchings in the limbs, the stools are tinged with blood, and membranous flakes are mixed with the egesta. When the person lives some time, general peritoneal inflammation is observed after death. Nitrate, and chlorate of potassa are irritant poisons in large doses, producing dangerous inflammation of the stomach and bowels.

The best remedies are large quantities of mild oil. The tests of the alkalis are obtained from their combinations with different acids, and the manner in which they colour the flame of the blowpipe. When nitrate or chlorate of potassa can be had in the solid form, the first may be known by its ready deflagration with charcoal in a crucible; the second by putting a drop of sulphuric acid on a mixture of the salt with sugar, which it instantly ignites.

4. *Ammonia and its salts.* They all act rapidly as irritant poisons, and have besides a violent effect on the nervous system, especially on the nerves of the spinal cord. This last effect is principally produced by pure ammonia and its carbonate. Convulsions are caused by the too long continued inhalation of the vapour of ammonia, which has several times proved fatal to man, terminating in severe bronchitis. For this species of poisoning, muriatic acid vapour is the best remedy. On the reception of carbonate of ammonia in the stomach, we should administer diluted vinegar instantly.

We detect the presence of ammonial vapour by the smell, and by a rod dipt in muriatic acid, which gives rise to white fumes of muriate of ammonia.

5. *Alkaline sulphurets* are all poisonous, chiefly from the

readiness with which they give out a large quantity of sulphuretted hydrogen gas, which is poisonous when inhaled, and when injected in quantity into the alimentary canal. The villous coat of the stomach, in cases of poisoning by alkaline sulphurets, resembles in colour the skin of a toad, and the muscular coat is congested with blood. The alkaline sulphurets act as narcotico-acrid poisons. Their presence is ascertained by a weak acid, and exposing a piece of paper dipt in sugar of lead to the fumes.

Acid Poisons.

III. Acid Poisons. The three mineral acids are only poisonous from their corrosive qualities, destroying rapidly the tissues to which they are applied.

1. *Sulphuric acid*, when strong, decomposes and blackens animal matters by evolving their carbon. It disorganises the fauces, gullet, and stomach; when not speedily fatal it lays the foundation of stricture of the gullet, and the patient is long harassed by dysuria and constipation. It is a felony to throw acid maliciously in the face.

2. *Nitric acid* destroys the animal tissues, and gives them a yellow hue, especially in the fauces, and when applied to the skin.

3. *Muriatic acid* destroys the tissues also, but renders the fauces usually whitish, as if the surface were of ivory. The symptoms produced by the three acids are similar, and the best remedies are the same for all, viz.—the copious use of mixtures of chalk or magnesia with milk.

The three acids destroy the clothes, corroding them when strong, and when diluted, staining them of a reddish brown. This circumstance becomes of importance in cases of maliciously throwing acid on any person, when no part of the acid liquid has been preserved. The stained portions of clothes, soaked in distilled water, will give out the acid; if sulphuric acid be present, it is best detected by nitrate of baryta, which gives a white precipitate, insoluble in pure nitric acid. Muriatic acid is detected by the addition of nitrate of silver, which throws down insoluble muriate of silver. Nitric acid is best recognised by its effect in destroying the colour of sulphate of indigo, when heated with it in a tube.

4. *Oxalic acid* is a most deadly poison. It differs from other acids derived from the vegetable kingdom in not containing hydrogen; being like the mineral acids, a binary compound. Its taste is so intensely sour that it cannot be employed as a secret poison; but it has been swallowed by mistake for sulphate of magnesia, so as to prove fatal. Its alkaline salts are almost equally poisonous, especially the binoxalate of potassa, or salt of *sorrel*, and they are speedily fatal when applied to wounds. Oxalic acid renders the tongue red and inflamed, and it corrodes the stomach; burning pain in the primæ viæ speedily come on, cold clammy sweats, a faint and fluttering pulse succeed, and palsy of the heart soon appears; proving that this substance is not only an acrid but a true narcotic. Unfortunately its effects are so violent and sudden that there can little be done by art to save the patient. Instant evacuation of the stomach, and the exhibition of chalk mixtures are the best means to be employed. Even when the person survives the immediate effects, he often dies of the inflammation or the corrosion of the alimentary canal.

The best mode of detecting oxalic acid is to precipitate portions of it by solutions of lime and magnesia. The precipitate by the first is not decomposable by any acid: sulphate of copper gives a precipitate with oxalic acid, insoluble in a little muriatic acid; and the precipitate with nitrate of silver, when dried, deflagrates with a gentle heat.

Simple Substances with Poisonous Qualities.

IV.—Simple Substances with Poisonous Qualities.

1. *Phosphorus*, even in very small quantities, is poisonous: two grains have proved fatal to a man. In that case there were sugillations on the belly and thighs, the scrotum was bluish and phosphorescent, the chest contained much fluid, dark blood, and the muscular coat of the stomach appeared inflamed, with dark spots about the cardiac and pyloric orifices. Evacuation of the stomach, and the administration of mucilaginous, but not oleaginous substances, are all the means we should employ to give relief in such cases. When the patient lives for some time, it will be difficult to detect the poison, unless the morbid appearances above noted may be considered as characteristic. Solid phosphorus is easily detected, by its inflammability.

2. *Iodine*, and *Hydriodate of Potassa*, are active substances, which, if given in excess, are apt to produce irritation of the system: vomiting, excessive languor, a feeble pulse, pains in the stomach, and cramps in the limbs; bilious vomiting and purging have followed large doses of iodine. It stimulates the liver, causes absorption of indolent glandular tumours; and, it is said, that its long-continued use has caused the disappearance of the testes and mammæ.

In dogs poisoned by it, the stomach was found inflamed, with numerous ulcerated points on its villous coat. No antidote is known. Its detection is easy. Boiled solutions of starch are delicate tests of the presence of iodine, or of hydriodic acid, by the intense blue colour produced. If hydriodate of potassa be present, the colour is evolved, on adding to the starch a drop or two of sulphuric acid.

3. *Bromine* is more poisonous than the last substance, but it is so rare a substance, that it is unnecessary to describe its effects or mode of detection.

Gaseous Poisons.

V.—Gaseous Poisons.—Of these some are fatal from the irritation they produce, A; others are narcotic, B.

A.

1. *Chlorine.*—This gas destroys life, if incautiously inhaled, by the irritation it produces. It causes violent constriction of the epiglottis, and severe pain in the chest, even when diluted. It disinfects air contaminated by animal emanations. Its solution in water kills dogs; and when injected into a vein, it speedily destroys life. It is most certainly detected by its smell.

2. *Hydrochloric gas*, or *muriatic acid gas*, is still more irritating and destructive. It is largely emitted in the manufacture of soda from salt, and is then most hostile to vegetation; $\frac{1}{36000}$ of it contaminating the atmosphere, so as to destroy plants.

3. *Sulphurous acid gas* is also most suffocating; is, even when much diluted, very destructive to vegetation; and has, as emanating from burning sulphur, sometimes been employed to commit infanticide. It renders the lungs very livid.

4. *Nitric oxide, and nitrous acid vapour*, are poisonous irritant gases, that cannot be respired, unless largely diluted. The attempt to respire the former nearly proved fatal to Davy. The fumes of the latter have accidentally proved fatal to individuals, producing burning sensations in the throat and chest, an expectoration of yellowish matter, and alvine dejections of a bright yellow colour. Before death the body becomes livid, the breathing laborious. Vapour of ammonia cautiously inhaled may relieve from the effects of this gas, of hydrochloric, and of sulphurous acid gases: but we have no means of detecting any of these poisonous gases, in the small quantity they ever can exist in the human chest, except by the sense of smell.

5. *Ammonia* is not only irritating when received into the lungs, but is, as we have already said, narcotico-acrid.

B.

6. *Nitrous Oxide*, the exhilarating gas of Davy, is narcotic, yet can scarcely be considered as poisonous, since it may be inhaled several times a-day without injury; but it seems to have a tendency to cause cerebral congestion.

7. *Sulphuretted Hydrogen* is one of the most poisonous of gases, destroying life when injected into the intestines, or into the cellular tissue, when received into the lungs, or even when extensively applied to the surface of the body. It is largely given out in the corruption of some kinds of animal matter. Many serious accidents from this gas have happened in clearing out the Parisian *fosses d'aisance.* The symptoms are instantaneous asphyxia, with discharges of bloody froth from the mouth, and convulsive movements of the limbs; motion and sensibility soon cease, the lips become livid, the eyes close, and lose their lustre, the surface becomes cold, the action of the heart is tumultuous, then feeble, and before death complete tetanus often comes on. Even when the gas does not kill, it produces severe tormina, nausea, and drowsiness. The body of one killed by it quickly becomes putrid; the skin is livid, and soon meteorized; the brain tender, and of a greenish hue. The proper treatment of persons suffering from this gas is to carry them into pure air, to dash cold water and vinegar over the body, to rub the surface diligently with warm flannels, but to admit air freely to the surface, while the palms and soles are to be strongly brushed. Lavements of cold water and vinegar should be first used, and then lavements containing common salt; when the heart beats violently blood should be abstracted.

This gas is well known by its smell resembling that of rotten eggs. Solutions of sugar of lead are very delicate tests of its presence in minute quantity.

8. *Carburetted Hydrogen*, of various qualities, is given out by stagnant waters. It is one of the results of combustion, and is abundantly produced in coal mines, where it is the formidable *fire damp.* When the atmosphere is much contaminated with it, it oppresses the breathing, and produces headache and giddiness. When mixed in the proportion of about $\frac{1}{12}$, with the atmosphere of mines, it will explode on the approach of a flame; yet in such an atmosphere persons will continue to work for some time with impunity; but even if there be no risk of explosion, the narcotic effects of the gas begin to be perceived on those long exposed to it.

9. *Carbonic Oxide*, mixed with other gases, is given out by burning fuel, especially if moist, and burning slowly. It scarcely becomes an object to the toxicologist in its pure state. It is inflammable, rather lighter than atmospheric air, and has a disagreeable smell. It may be respired when diluted; but produces temporary intoxication, and when injected into the veins gives the blood a brown colour.

10. *Carbonic Acid.*—This gas is well known to be heavier than atmospheric air, to be totally irrespirable when pure, and to be speedily fatal to animals plunged in it. It is always present in the air in minute quantity; but is largely given out by the burning of all sorts of fuel, is produced in every species of fermentation, is formed in the respiration of all animals, and, under certain circumstances, it is given out by plants, particularly in the dark. From these sources, the air, in confined situations, may become impregnated with it, in a proportion inconsistent with the safety of man. Numerous instances of its fatal effects have been observed in the neighbourhood of large fires, in breweries, in crowded apartments; and in rooms where many plants are growing, it is unhealthy to sleep. When a confined atmosphere is much mixed with it, uneasy respiration is speedily felt, and the person may escape the danger by seeking the open air; but at other times drowsiness or stupor comes on, before any warning is given, and the individual loses the power of attempting his escape. When the gas is undiluted, it is almost immediately fatal to animals immersed in it; and even if the animal be made to respire pure air, while the whole body, except the head, is immersed in carbonic acid, life will be extinguished. After death from this gas, the features remain placid, the eyes open and brilliant, the body long retains its heat and flexibility. When the person has not been exposed long enough to extinguish life, the breathing may be stertorous and oppressive, the face flushed, the pulse feeble, the eyes prominent and wildly rolling about, the tongue swollen, and the saliva flowing out of the mouth.

The proper treatment consists in removing the patient into the open air, or into a well-ventilated room; the surface should be sprinkled with vinegar and water, and every few minutes rubbed dry with hot towels. If the valve bellows be at hand, the foul air should be first drawn from the lungs, and its place immediately supplied by fresh air, thrown in by the same machine. This alternation may be two or three times repeated, and then we should imitate natural respiration as much as possible, throwing in air by the bellows, and aiding the expulsion of the air by gentle pressure on the chest. Brushing the soles of the feet and palms of the hands with stiff brushes, stimulating the nose by a feather, or by ammonia, are useful auxiliaries. When animation is restored, it is time enough to put the patient to bed.

Vegetable Poisons.

VI.—VEGETABLE POISONS.—These include most of the narcotic and narcotico-acrid poisons of Orfila. Narcotism begins with a sense of fulness in the head, then succeed a sort of intoxication, dizziness, headache, loss of voluntary motion, almost amounting to paralysis, sometimes convulsions, and finally, stupor and coma. These symptoms may not all be present; for each poison has its peculiar modification of the general symptoms. The *post mortem* examinations of those who perish by narcotic poisons do not generally throw much light on their mode of destroying life; and there are some diseases that bear considerable resemblance to narcotism. Thus, *Apoplexy* chiefly differs in there having usually been some warning before the fatal attack, and in coming on during a meal. Narcotism is generally perceived from half an hour to one hour, or more, after taking the poison. Narcotism is more gradual than apoplexy, and at first the person may be roused from his stupor. Apoplectics generally survive for a day, or often much longer. *Epilepsy* may generally be distinguished by the history of the case, by the abruptness of the attack, by the person being instantly rendered insensible, and by its rarely proving fatal on the first attack. One species of fatal *syncope* is more difficult to be distinguished from narcotism; and if it has not been witnessed, we do not know how it can be recognised after death.

1. *Opium.*—The deadly effects of this substance have been long known; and it was supposed to be a proximate vegetable principle, simple in its nature, and peculiar in its effects. Modern chemistry has shewn that opium, like many other active vegetable substances, owes its qualities to an *alkaloid*, which may be separated, by chemical processes, from many other ingredients. The first of these alkaloids was detected in opium about 1812; and the care with which this important drug has been since examined, has shewn it to be an exceedingly compound substance, consisting of not less than of sixteen, or perhaps of seventeen different vegetable principles, of which nine are crystallizable. Of these, in a toxicological point of view, the most important are *Morphia* and *Meconic acid.* These two ingredients appear to exist in combination in opium; and when magnesia is added to a watery solution of opium, an insoluble meconate of magnesia is formed, from which the morphia, sparingly soluble in water, is taken up by alcohol; or, if we add muriate of lime to the liquid, instead of magnesia, we obtain meconate of lime, as an insoluble precipitate, and a soluble muriate of morphia; which last, when purified by several nice chemical manipulations, is obtained in minute, white, silky crystals. This is the valuable part

of opium to the medical practitioner, as it is powerfully hypnotic, and is less liable to cause headache, nausea, and itching of the skin, than crude opium.

When either this substance or opium are administered in an over-dose, the symptoms are drowsiness and insensibility, but this state is often preceded by a slight excitement: the face assumes a ghastly hue, the jaw falls, the eye-lids remain half open, the pupils are strongly contracted, stupor and complete coma succeed; convulsions are rare in adults, but often are seen in infants. Adults in general die easy from this poison. Opium produces its fatal effect, however introduced into the system, and even when applied to a raw surface, has destroyed life. Morphia is stronger than opium, in the proportion of 6 to 1.

The principal morbid appearances are great turgescence of the vessels of the brain, and sometimes serous effusion between its membranes, or in its ventricles; the lungs are gorged with blood, the stomach rarely appears inflamed, the blood is found fluid in the heart, and the body runs rapidly to decay.

Evacuation by the stomach pump, or by emetics, is the remedy chiefly to be trusted; and after the patient is roused, we must prevent him falling asleep while any tendency to stupor is perceived. Artificial respiration appears to have saved one person who was found comatose. No antidote is known.

The best tests of crude opium are those which shew the presence of morphia and meconic acid. The contents of the stomach, in a case of the poisoning with opium, may have the smell of that drug. The whole should be emptied into a clean mortar, and reduced to a thin pulp by the addition of distilled water; acidulate the whole with acetic acid, strain and filter, then reduce the liquor to the consistence of a syrup by a gentle heat: add alcohol gradually, boil, and filter when cold. The spirituous solution will contain all the morphia. Again, evaporate to the consistence of syrup, and add magnesia, which will throw down meconate of magnesia and the morphia in the form of a greyish powder, which may be freed from much of its colouring matter, by washing it with cold water, and then with cold proof spirit. The morphia may now be separated from the meconate of magnesia by hot strong alcohol: concentrate this last solution, which will have a bitter taste, which, on adding a drop of nitric acid, will strike an orange yellow colour, soon passing to golden yellow; and will give a duck-blue with permuriate of iron.

The meconate should be decomposed by muriate of baryta, which will form an insoluble meconate of baryta; from which the addition of very diluted sulphuric acid separates the meconic acid. This acid has a silky lusture in the state of crystals, and affords, with permuriate of iron, a very intense red. There is only one source of fallacy in operating with meconic acid from the human stomach, which must be guarded against, namely, that the sulphocyanates of the alkalis precipitate permuriate of iron of a red colour, and some of the secretions, as the saliva contain a sulpho-cyanate. If the solution of morphia be strong there is no danger of mistake; because of the intensity of the colour produced. Professor Forbes has also shewn that the two solutions affect the prismatic spectrum in a different manner; though perhaps this test is less applicable to medico-legal causes, where the quantity of ingredients is generally very minute.

2. *Hyoscyamus niger.* The whole plant is narcotic, especially the roots, which have several times caused fatal effects, by being eaten instead of parsnips. The symptoms are active delirium, in which persons have danced and reeled about until stupor supervened. In persons fully under this stupor, stimuli cease to rouse, and the eye is insensible to light, or even to being touched. Emetics are the reme dies; but we have no particular tests of this poison.

3. Besides Hyoscyamus, other *solaneæ* are narcotic. This is especially the case with *solanum nigrum* and *s. mammosum.* Both owe their activity to an alkaloid, *Solanea;* which is capable of exciting vomiting, hurried respiration and stupor.

4. *Lactuca virosa* is a poisonous plant, with a juice that is highly narcotic, and has the smell of opium. This juice, when inspissated, forms the *lactucarium* of the shops, which was at first derived from the *lactuca sativa,* but is obtained in greater quantity, and of precisely the same quality, from *l. virosa.* Stupor and coma follow an over-dose of lactucarium.

5. *Hydrocyanic acid,* or *Prussic acid* forms the poisonous ingredient in an important class of vegetables. It is yielded by the kernels of the *bitter almond,* and of several other species of that genus; by the leaves of the cherry laurel, or *prunus lauro-cerasus,* by the *prunus padus;* and probably is contained in the seeds of the *pomaceæ,* and in all vegetable productions with the odour of bitter almonds. The acid, when concentrated, is the most deadly of all poisons; producing almost instant death, whether swallowed or introduced by a wound. Even the diluted hydrocyanic acid of the apothecary's shop is fatal in a very moderate dose; and the essential oil of bitter almonds is not less so. An infusion of the leaves of cherry-laurel is a very deadly poison: bitter almonds have sometimes proved fatal; and the same effect has followed on eating the blossoms of the common peach, *prunus persica,* in a salad. When the preparation is concentrated, the death is very speedy: the breathing immediately becomes laborious, convulsive movements of the limbs come on; in dogs it ends in violent tetanus. After death the eyes are glistening, the pupils dilated, the muscles of the spinal column stiff, the countenance pale and often composed, the abdomen drawn in; the veins of the brain are found to be loaded with black blood, and the blood in the heart and great vessels is generally fluid. In some instances the blood and cavities of the body have exhaled a strong odour of prussic acid; and the blood has been said occasionally to have exhibited a bluish tint when the strong acid has been administered. The bile has often been observed to be of a dark blue hue in such cases.

No remedy can be of service in poisoning by this substance, unless instantly administered: but ammonia appears to have a great power in alleviating the symptoms when the quantity of hydrocyanic acid has not been very great. Ammonia diluted with water should be introduced into the stomach; its fumes sufficiently diluted with air allowed to enter the lungs, taking care not to excoriate the air passages by the too free use of the ammonia. Another very powerful antidote is chlorine. It is most advantageous to employ the vapour of water containing about one fourth part of its volume of chlorine gas. This may be inspired without risk; it has saved the lower animals when the poison had been administered for five minutes before its application, even after the convulsive stage had passed, and that of insensibility had supervened. In Orfila's experiments, in ten minutes after inspiring diluted chlorine in this manner, the recovery of the animals was certain. Herbst of Göttingen states, that dashing cold water on the surface of the body, is a powerful antidote in such cases: it is most successful *before* the convulsive stage, but is useful during the spasms.

The tests of hydrocyanic acid are certain when we can obtain it in quantity: but when we must look for it in the body, the smell is its best criterion. The stomach and the blood will sometimes have its peculiar odour for more than three days after death; and if the body has been buried within twenty-four hours, the odour will occasionally remain till the eighth day. When we can obtain a little of the liquid acid; nitrate of silver is a very delicate test. A white precipitate is formed, which, when dried and heated in a tube, gives off *cyanogene*, a gas that burns with a rose-coloured flame. If we add to the suspected liquid sulphate of copper, a rich emerald green solution is formed: and if to another portion of the liquor we previously add a drop or two of potassa, that test will throw down a greenish salt, which is partially dissolved by hydrochloric acid, leaving behind a cyanide of copper, which will yield cyanogene like the precipitate of silver. This test will detect prussic acid in 20,000 times its weight of water.

Strychnia, and the Plants from which it is obtained.—This alkaloid, and the plants producing it, all act in the same manner, being very poisonous, and causing speedily severe spasms, ending in tetanus and asphyxia from fixation of the muscles of respiration. Strychnia was first obtained from the seeds of *Strychnos nux vomica* in 1818, by Pelletier and Caventou; but it exists in still larger quantity in those of *Strychnos Ignatii.* The powder of the seeds is first exposed to the action of nitric æther, to separate a large quantity of oil, and is then digested with diluted sulphuric acid; the acid is next separated by means of lime or magnesia, and the alkaloid taken up by boiling alkohol. This was supposed to be pure *strychnia;* but it was afterwards found to be mixed with another alkaloid of somewhat similar properties, which was first obtained from a bark imported into Europe as that of the true angostura bark, or *Galipea officinalis.* It was found to be very poisonous, and was supposed to be the bark of *Brucea antidysenterica.* Hence this new alkaloid was named *Brucia.* But it has been more lately discovered that the bark was not a production of South America, but of India, and really was the bark of *Strychnos nux vomica*, which contains a larger quantity of brucia, with some strychnine, than the seeds of the plant. According to some, the poisonous energy of the strychnia to brucia is 6 to 1; others say as 24 to 1. The two alkaloids, when mixed, as they always are in the strychnia of the shops, may be separated by dissolving the impure salt in very diluted nitric acid to saturation, and crystallizing the solution; the nitrate of brucia forms short, solid prisms, while the salt of strychnia exists in soft silky tufts, which, by agitation, may be poured off with the mother water from the crystal of nitrate of brucia. Both alkaloids may be obtained pure by carbonate of soda, and taken up by boiling alkohol.

Pure strychnia is a most deadly poison: a single grain would probably destroy a man, and even less if inserted in a wound; but it is still more fatal to dogs and to cold-blooded animals. Yet this energetic substance is used, in minute doses of one-eighth grain, as an internal remedy, and also externally, for the cure of paralysis; but its effects must be carefully watched. Its taste is so intensely bitter that it may be thus detected when diluted in 100,000 times its weight of water. No antidote is known for this deadly poison, though some have supposed that iodine may be useful, as in some other instances of vegetable poisons.

The powder of the seeds of *Strychnos nux vomica*, or of *S. Ignatii*, are deadly poisons. Fifteen grains of the former, and still less of the latter, have proved fatal to man, with tetanic symptoms, after anxiety, spasms of the muscles of the limbs, rigidity of the spinal column, livid face, and impossibility of breathing. These symptoms come on in paroxysms, with intervals of relaxation that become shorter towards the fatal termination. The intervals are marked by nausea, profuse perspiration, and a very feeble pulse; and the victim from a large dose seldom lives an hour. When the death is rapid, the body exhibits little marks of inflammation; but when it has been lingering, the stomach shows traces of violent inflammation in its violet colour, and in some cases gangrene, with a serous effusion in the head and spine, while the blood generally remains fluid. The human body usually retains the rigidity of the muscles after death; but in dogs they have sometimes lost their stiffness just after death.

The celebrated Javan poison is prepared from the juice of *Antiaris toxicaria* and *Strychnos tieuté*, or *chetik*, plants belonging to the natural order of *Apocyneæ;* and another plant of the same order, *Cerbera tanghin*, is said to be so poisonous that a single seed will destroy twenty persons.

The *woorali*, or *wourara* poison of South America, has been found by Schomburgh to be prepared from a decoction of a new *Strychnos*, which he names *S. toxicaria;* and we are informed by Hillhouse and Waterton, that the Indians, during its inspissation, add the juice of bulbous roots and the poison of snakes. We have found very small quantities of this poison, though kept for years, speedily to destroy animals, without violent convulsions.

It becomes of much importance to be able to detect the administration of strychnia and brucia; and the following is an outline of the method, premising that they are less liable to lose their qualities by decomposition in the dead body, than most of the vegetable alkaloids, and may be detected in very minute quantity.

When the powdered seeds of any of the *Strychneæ* are administered, they are usually found adherent to the coats of the stomach, and may be recognised by giving an intensely bitter taste to alkohol, and by forming a deep yellow colour with nitric acid; and the alkaloids may be obtained from them as above.

Strychnia and brucia may be separated from the contents of the stomach by boiling that with vinegar, which will dissolve the alkaloids, while it coagulates the animal matters present; and the mass in the filter may be again boiled with alkohol, and this filtered liquid added to the acetous solution, concentrated by a moderate heat, and the residue will have an intensely bitter taste. 1. To one portion add nitric acid, which will, if brucia be present, give a deep yellow colour. 2. To another portion add chloride of gold, which will throw down a rich yellow precipitate with strychnia; but brucia is not precipitated by this reagent. 3. Acidulate bichromate of potass with sulphuric acid, and add this to a third portion: no precipitate falls; but where strychnia is present, the mixture becomes of a pale blue colour, and retains its transparency. 4. The most decided test of all is the introduction of a few drops of the liquid into the thorax of a living frog, as proposed by Dr Marshall Hall; and even the $\frac{1}{18000}$th of a grain of strychnia will thus produce violent convulsions in the animal.

7. *Tobacco*, a well known narcotic, of difficult detection, except by the smell. Nicotine is its poison.

8. *Atropa Belladonna*, or deadly nightshade, is a strong narcotic poison. All the plant is poisonous, especially the leaves and the fruit. The symptoms produced are delirium, dilated pupils, and loss of vision. Sometimes it causes hysterical bursts of laughter; the lips, tongue, and throat are parched; there is a great sense of sinking, with tremulous movements of the hands; but convulsions are rare. Many instances of poisoning have happened from eating the berries and the young shoots. The active principle is an alkaloid, *atropia.*

9. *Datura Stramonium* is another poison sometimes employed on the Continent to facilitate robbery or rape; and in this country it has been administered by mistake. It owes its activity to an alkaloid, *daturia*, which abounds also in *D. tatula.* The extract of stramonium produces dryness of the fauces, intoxication, and active delirium, with cerebral congestion.

10. Various *umbelliferous plants* are poisonous; such as *Conium maculatum*, *Æthusa Cynapium*, and *Lactuca virosa.* The roots and leaves contain a poisonous juice; and the symptoms are those of narcotics, with some degree of irritation. Various authors have spoken of the *Œnanthe crocata* as very poisonous; but Dr Christison gave it largely

to dogs without killing them. *Conium maculatum* owes its activity to an oily alkaline principle, *conia*, which smells strongly of mice, and becomes, though a clear liquid when cold, opaque on being heated.

11. Several of the *Ranunculaceæ* are acrid and narcotic, as the *Ranunculus sceleratus, R. flammula, R. bulbosus, R. lingua, R. acris*, and *R. arvensis;* but we have no mode of detecting their poison.

12. *Aconitum napellus* produces delirium and stupor, with burning in the throat, vomiting, and purging.

13. *Helleborus niger* is a narcotico-acrid poison of great activity.

14. Several other poisonous plants may be mentioned, such as *Anemone pulsatilla* and *Cytisus laburnum;* the seeds of the latter are narcotic. In all these cases the best remedies are emetics.

15. *Digitalis purpurea* owes its activity to *digitalia*, an alkaloid which may be obtained from it. The chief characteristic of digitalis is its extraordinary power in reducing the force and frequency of the pulse; on which account it is used in medicine; but it is poisonous even in small doses.

16. The other narcotico-acrid poisons of the vegetable kingdom we shall briefly notice, indicating such as have yielded alkaloids to analysis. Of these, *Menispermum cocculus* is one, the active principle of which is *picrotoxia: Delphinium staphysagria*, the seeds of which yield *delphinia; Chelidonium majus; Arum maculatum; Juniperus sabina; Veratrum album*, which yields *veratria*, an alkaloid lately introduced as an external application, and nearly resembling another poisonous alkaloid, *colchicia*, obtained from *Colchicum autumnale; Bryonia alba*, said to afford *bryonina; Euphorbia officinarum; Hippomane mancinella;* various species of *Jatropha*, which yet by cooking yield wholesome food; the seeds of *Ricinus communis;* seeds of *Croton tiglium; Cucumis colocynthis; Momordica elaterium; Scilla maritima;* various species of *Daphne;* several species of *Rhus; Hebradendron gambogioides; Convolvulus jalapa*, and *C. scammonea*. To these some add *Narcissus pseudo-Narcissus, Gratiola officinalis, Caltha palustris*, and *Lobelia inflata*.

17. *Poisonous Fungi.*—Several of this natural order are poisonous, especially those belonging to the genera *Amanita* and *Agaricus*. Their poisonous qualities appear to depend on two principles; one of which is volatile, and disappears on boiling, drying, or macerating in a weak acid. To this principle Le Tellier ascribes the irritant quality of poisonous mushrooms. The other is not volatile, is soluble in water, unites with some acids into crystallizable compounds, and appears to be an alkaloid now termed *fungia;* on this the narcotic properties of these plants depend. The time in which the symptoms occur, after the fungi have been eaten, is very various; often not until twelve or even twenty-four hours. The sufferers are often relieved by vomiting; but if not, the surface becomes livid and cold, violent colic ensues, and death is preceded by delirium and deep coma. The corpse is livid all over, the blood fluid, and sanguine discharges are apt to flow from the mouth, nose, and eyes.

18. *Secale cornutum.*—The *ergot of rye* produces, when eaten in bread, many of the symptoms of mushroom poison. Decandolle ascribes this disease of grain to a fungus of the genus *Sclerotium;* and it has been found to yield a principle resembling fungia. The tendency of this substance to produce dry gangrene is generally admitted by German and French writers. There is a learned dissertation on it by Dr Wiggers, in which its fungoid origin, and its peculiar action in promoting the expulsive efforts of the gravid uterus, seem to be established.

19. *Alkohol and Æther* may be here considered, as being derived by art from vegetable matter. They are well-known narcotics, producing at first intoxication, and afterwards stupor and cerebral congestion. They are also irritants; the stomach of persons killed by them being often inflamed. When the moderate use of spirit does not produce death, it may give rise to *delirium tremens*. The smell of spirit is often perceived in the cavities of the chest and abdomen of those who have died from drinking. The stomach-pump and milk are the best remedies.

20. *Camphor*, a concrete essential oil, has pretty strong narcotic qualities. It is best detected by its peculiar odour.

VII.—Animal Poisons.

Animal poisons.

1. *Cantharides.*— An acrid poison, is contained in the body of the *Cantharis vesicatoria*. It is found to reside in a whitish matter, resembling spermaceti in colour and consistence, which is united to three other marked principles. The first is a green oil, soluble in spirit, but not in water; the second a blackish matter, soluble in water, not in spirit; the third a yellowish viscid matter, soluble both in water and in spirit. This last is united in the insect with *cantharidine*, and renders it soluble in water, which it is not when pure.

The symptoms of poisoning by cantharides are intense burning heat in the primæ viæ, painful deglutition, pain in the stomach and bowels, bloody vomiting, painful micturition, and priapism, intense desire to void urine, and distressing pain in the whole urinary organs: frightful convulsions and tetanic spasms usher in the fatal termination. When the flies in substance have been swallowed, the fragments of their green *elytra* are found adhering to the villous coat of the stomach; and this has been observed even after the body has been buried for months. There is no antidote for this poison. Evacuants and mucilages are the best remedies. Oil given by the mouth increases the evil by dissolving the cantharidine; but oil thrown into the bladder is useful in allaying the irritation.

2. *Fish Poison.*—This singular subject is little understood, except that, in certain seas, and in certain seasons, fishes, at other times wholesome, prove deadly poisons. This is chiefly the case with the *yellow-billed sprat*, the *barracuta*, the *grey snapper*, the *Sparus venenosus*, and *grey labrus* of the West Indies; with several species of *Diodon* and *Tetrodon*, and with *Aplodactylus punctatus*, of the Southern Ocean. The rapidity and fatality of the poison has been described by Chisholm, Ferguson, and Thomas. The symptoms are,—irritation in the throat, tingling of the surface, burning heat in the stomach and bowels, colic, nausea, spasms, giddiness, coma, and death. It is said that persons have died whilst masticating a portion of the fish, ere any of it was swallowed. The juice of the sugar-cane, and various sweet liqueurs, are said to be useful in the slighter cases.

Fishes in this country are sometimes poisonous; and mussels have occasionally with us produced death, with less rapidity, but with symptoms of the same kind. The cause of the poisonous quality of fish is, with some probability, attributed to their having fed on acrid mollusca.

The flesh of birds is occasionally poisonous; as happens to the *Phasinanidæ* of North America when they have fed on the buds of the *Kalmia latifolia*. The honey of the bee, in like manner, is poisonous when it has fed on the sugar of the *Rhododendron* and *Kalmia*, as is described by Xenophon, Pallas, and Dr Smith Barton. In the former case the honey produced a species of madness; in the latter the symptoms were similar to what occurred to the soldiers of Xenophon.

3. *Animals have a poison generated in them by disease*, which is capable of infecting those who eat, or even touch their flesh. The best known instances of this is in the *Pestis bovilla* or *murrain* among domestic animals, by which their flesh and juices become deadly poison to other ani-

mals. This appears somewhat analogous to the accidents that happen in dissection.

4. *The bites of rabid animals* belong to the same class of poisons. The bite, for instance, of a rabid dog will destroy other animals; after some time they become delirious, than paralytic, and invariably die rabid. In man similar symptoms occur, to which is superadded hydrophobia,—a symptom never observed by Mr Youatt in any animal except *man.* Excision of the wound, or destruction of the part by caustic, is the best prophylactic; *Belladonna* and *Scutellaria lateriflora* seem to have some preventive power, according to the same authority; and excessive bleeding seems to have arrested or cured the disease in India.

5. *Bites of Snakes.*—Poisonous snakes are provided with two or more teeth placed on a moveable bone, on each side of the upper jaw, and corresponding to the maxillary bones of other animals. These teeth or fangs are hollow, and have their roots connected with a duct that conveys the poison from a bag placed under the principal muscles that close the jaws; so that when the animal bites, the poison is squeezed from the bag, and is instilled, through the hollow of the fangs, into the wound. The symptoms, in general, are in proportion to the quantity of the poison compared to the size of the animal bitten; the smallest animals suffering most. The general symptoms are,—pain in the part wounded, trembling, weakened respiration and circulation, and coma. The most poisonous snakes are the *rattlesnake* and *trigonocephali* of America, and the *cobra de capello* of India: the *viper* of this country and of France sometimes produces fatal accidents. Excision of the part, sucking, or cupping the wound are to be tried; and both ammonia and arsenic given internally appear to have considerable power in curing the bites even of the most deadly snakes.

6. *The stings and bites of Arachnidæ and Insecta* are poisons of a similar kind. The complex apparatus of the sting of the bee and wasp convey poison to the wound so acrid that horses, asses, and also men, have died from numerous stings. The sting of the scorpion, and bite of *Scolopendra morsitans,* as well as of spiders, are inflicted with a poisoned apparatus analogous in structure to the fangs of snakes.

Imaginary poisonings.

VIII. Imaginary, Pretended, and Imputed Poisonings, require much patience and attention on the part of the medical jurist. To them no general rule can be applied, but they must be treated according to the nature of each peculiar case.

PART II.—MEDICAL POLICE.

SECTION I.—CIRCUMSTANCES AFFECTING THE HEALTH OF INDIVIDUALS.

Cleanliness.

I. Cleanliness.—This subject may be considered under three heads.

1. *Personal Cleanliness* is valued by all nations in proportion to their advance in civilization, and exercises an important influence on the health of individuals. Most savage nations are disgustingly deficient in this virtue; but the polished nations of antiquity paid great attention to it, as is evinced by their general use of baths, the stupendous ruins of which still surprise us in the remains of their cities. In modern times, especially in Great Britain, warm and cold bathing are far less employed than is desirable; and we cannot help regretting the want of public baths for all ranks, especially in our manufacturing towns, where the luxury of warm or tepid bathing might be very cheaply obtained, by collecting the waste water from the *condensing backs* of steam-engines. Bathing, by removing sordes and remains of perspiration, keeps the skin in a fit state for its important functions. Public baths should be established in every town, and all children should be taught to swim. The warm and vapour baths of Northern Europe prove how cheaply such luxuries might be obtained for the great mass of the community.

2. *Domestic Cleanliness* is perhaps better understood by the Dutch and the English than by any other nations in the world. This virtue has been long practised in Holland, but is comparatively only of late origin in Britain. The picture which Erasmus draws of English manners is not very flattering; and our own historians prove that it was not until after the civil wars of the seventeenth century that the English became a cleanly people. Now no nation can surpass them in domestic cleanliness, and none equal them in domestic comfort. The effect on the health of the inhabitants is shown by the less frequent attacks of severe epidemic diseases in modern times, and perhaps also by the increased value of life annuities.

3. *Ventilation of Habitations* is one important part of domestic economy, now better understood; and Strutt, Sylvester, and Murray have taught us how ventilation may be combined with warmth. The renewal of the air, vitiated by respiration and combustion, is secured by simple contrivances, and the air admitted into apartments is warmed by passing between a close stove or cockle and an exterior covering.

Aliment.

II. Aliment.—Under this head may be considered,—

1. *Preparation of Food.*—Alimentary matters are rendered more wholesome and nutritive by cooking; and the mystery of that art is not unworthy of consideration, even were it not also the means of economizing the sustenance, and increasing the gratification of man.

2. *Culinary Utensils* deserve attention here, because the wholesomeness of aliment often is materially affected by them. There is risk of cooking food, especially of the acescent or oleaginous kinds, in copper vessels, though the danger is diminished by keeping the utensils always bright, and not suffering the food to remain in them after removal from the fire. Vessels of lead and pewter should be entirely banished from the kitchen, as they are never without danger, from the ease with which they are acted on by acids. Tinning copper vessels renders them safe as long as the coating of tin lasts; but the vessels usually made of pewter, an alloy that contains lead, should be replaced by those of block-tin or of tinned iron. The objection to the last kind of vessels is their little durability, and the lead solder with which they are put together. Vessels of iron are durable and cheap, but they blacken some kinds of food: this is best obviated by a coating of tin. Vessels of gold and silver are far too expensive for ordinary use; but copper is often covered with a thin plate of silver, forming what is termed plated ware, which is excellent while the silver remains on the copper. A thinner coat of silver is applied in some instances by means of an amalgam of silver, and a similar process is commonly used to gild the inside of silver or of plated ware. *Pottery* is a valuable addition to culinary utensils. It is of all qualities, from the purest porcelain of China or of Europe to the coarsest earthenware. The glazes which contain lead are objectionable where acids are to be used; but if well baked, such glazes are not readily acted on. For chemical experiments the porcelain of China or of Germany, in which there is no lead, is always preferred, and it would be so also for culinary purposes but for the expense. These glazes are made with felspar, or with mixtures of flint and alkalies.

3. *Adulterations of Food* may be accidental or designed. We have just stated how lead and copper may find their way into food; but there are other accidental adulterations. Farina or flour may be rendered unwholesome by the pre-

sence of the *ergot*, the *smut* of wheat, and the seeds of *Lolium temulentum*; which last acts as a narcotic. Flour may also be mixed with sand, from the use of too soft millstones, with other impurities, from want of care in winnowing or grinding; or by fraudulent mixtures of chalk and gypsum. Bread may be mixed with chalk, magnesia, potassa, soda, or alum, to conceal bad flour; and it has been sometimes adulterated with white lead. These adulterations are easily detected. On rubbing down the bread into a pulp with water, the heavy particles will subside to the bottom and may be collected; the alum, alkalies, or lead may be detected by chemical tests. Butcher meat may be unwholesome from disease in the animal, or by long keeping. Butter may be deteriorated by containing too much salt or water. Water may be unwholesome or disagreeable from corrupting animal or vegetable matter; from being too hard,—that is, containing too much saline or earthy ingredients. Soft water may be adulterated by passing through leaden pipes, or standing in cisterns of that metal. Milk may be fraudulently mixed with water, or with magnesia and chalk. Malt liquors have been purposely adulterated by *Cocculus indicus, Lolium temulentum*, &c., to increase their intoxicating qualities. Wines have been chiefly adulterated by brandy, to give them strength; by preparations of lead, to correct acidity and impart astringency. This last ingredient is best detected by a test consisting of a solution of tartaric acid impregnated with sulphuretted hydrogen. The chief adulterations of spirit are by water, which is detected by the hydrometer; and by lead, accidentally introduced from the worms of the stills. Lead is readily thrown down by infusion of galls, which will convert new unwholesome spirits into good spirit. Vinegar is liable to contain lead and copper, from the pipes and cocks through which it flows. These metals are easily detected by sulphuretted hydrogen and ammonia.

Police of drug-shops.

III. POLICE OF APOTHECARIES' SHOPS.—The supply of good drugs is regulated in many countries by the government. Inspectors are appointed, who examine and report on the state of the drugs found in the premises of dealers, and any infringement of the laws is rigorously punished. In our country the inspections are a mere form, of little or no utility. They should be made by persons paid by the state and competent to the task, whose office should be honourable.

Clothing.

IV. CLOTHING.—The importance of paying attention to the qualities of clothing is generally admitted. The advantage of flannel or cotton next the skin to persons of a consumptive habit, or of otherwise delicate constitutions, and also to soldiers and sailors, or other persons whose occupations are laborious, is acknowledged. The use of linen next the skin is suitable for the young and robust; but as persons advance in life, cotton or woollen under-garments are advisable.

1. The *Male Dress* should afford sufficient protection to the parts it covers, and should not impede the free use of the limbs. The covering of the head should defend the eyes from excess of light, and the head from the sun. Anything tight about the neck is injurious. Those who take much exercise will find useful support from broad belts round the waist; especially as they advance in life.

2. The *Female Dress* should keep the body comfortably warm. Compression of the chest and abdomen of females is far too general; and the ribs of most of our ladies are deformed by tight lacing. This practice diminishes the cavity of the chest; it confines the stomach and liver excessively, and has a tendency to contract the width of the pelvis. By the first, consumptive diseases are induced; by the second, the function of digestion is injured; by the last, the perils of child-bed are increased. The practice of tight lacing is ancient. It is severely stigmatized by Juvenal; and is condemned by all modern authors. Excessive exposure of the bust is also too general among women, and often lays the foundation of disease.

Temperance.

V. TEMPERANCE.—Its importance to health, to vigorous youth, and to honoured age, need not be insisted on. Gluttony is not less destructive, and is even more disgusting than drunkenness: both are sure to end in debasement of the mental faculties, and destruction of the bodily health.

Exercise.

VI. EXERCISE.—Regular exercise in the open air is highly conducive to health; and those who are interested in the improvement and happiness of the lower classes in our towns cannot help lamenting the little that has been done to encourage our artizans and shopkeepers to take outdoor exercise in pure air.

The philanthropist must remark with regret the circumscription of the means of enjoying fresh air, which the inclosure of commons and of waste lands near towns and villages has produced, and the discouragement by officious magistrates of the outdoor games and pastimes of the lower orders. Part of the sums so frequently left to endow hospitals and alms-houses would be more rationally expended on gymnasia for the encouragement of healthy sports in the open air, or on public walks for the recreation of our citizens.

Prostitution.

VII. PROSTITUTION.—In most parts of the Continent the state has interfered, not, as is falsely alleged by some, to raise a revenue from this polluted source, but to secure the rising generation, as much as possible, against the fearful consequences of diseases that sap the foundations of a nation's strength, by impairing the sources of a healthy progeny. The unfortunate class of females, who may generally be considered as the victims of male licentiousness, are there regularly registered, and subject to domiciliary visits of the authorities, who send them to hospitals when disease first makes its appearance. The arguments against this practice are not more rational than it would be to forbid the medical practitioner to lend his aid in other cases where the imprudence of the sufferer was the cause of his malady.

Celibacy and marriage.

VIII. CELIBACY AND MARRIAGE.—In the most polished states of antiquity marriage was enjoined by positive enactments, and enforced by penal statutes; in modern times legislators wisely leave it to the sense and discretion of individuals. In fact, the propensity to celibacy is so small in most persons that marriage may be safely entrusted to individual will. The tendency to increase and multiply is so forcible, that it will generally be found to produce a population up to the very limit of the means of providing for children. It was for advocating this philosophical truth, and for pointing out the natural checks to a redundant and miserable, because destitute, population, that Malthus has been abused by sciolists and pretended philanthropists, who appear, from their senseless declamations, either never to have read his works, or not to have comprehended their import.

Lactation.

IX. LACTATION AND CARE OF OFFSPRING.—The important duty of rearing the helpless infant devolves by nature on the female parent; and in general it can never be so well performed by any other individual. In an artificial state of society, however, many females become mothers who are not able to nurse their children. In such cases we would recommend the employment of a wet nurse, as affording the best chance of rearing the infant. The child should not be long fed *exclusively* from the breast, because its stomach should be gradually accustomed to other food before it is weaned. The infant is totally dependent on the care of those around for its preservation. To retain it healthy, it should undergo daily ablutions, have its clothes of suitable warmth, easy, and frequently changed. Its food should be chiefly of milk and farinaceous matter for the first two or three years. It should have regular exercise in the open air; and not be confined in its early years to too sedentary occupations. The dreadful mortality in foundling hospitals proves the importance of the circumstances alluded to under this head.

Profession and trade.

X. Effects of Profession and Trade on Health.—This is a very important consideration, and may be divided into various heads.

1. *Diseases incident to affluent idleness* are chiefly such as arise from indolence and want of some definite object of pursuit: hypochondriasis, tedium vitæ, dyspepsia, gout. For these the best remedies are, rural amusements, intellectual pursuits, mingled with sufficient inducements to take exercise in the open air.

2. *Diseases of Literary Men* are chiefly produced by want of attention to regular exercise in the open air, giving rise to dyspepsia and constipation; by inequalities in the time of eating and sleeping; and by excessive use of the eyes in artificial light. They are best obviated by abridging the hours of study, and mingling sedentary avocations with active and social occupations. Literary men, however, especially in France, have been a long-lived race.

3. *Clergymen* have a wholesome intermixture of sedentary with active duties; and, if their lungs be sound, they are generally long-lived.

4. *Lawyers*, when their occupations are chiefly at the desk, are subject to the diseases of sedentary persons; but barristers, when not excessively harassed by toil, may generally be considered as engaged in a healthy occupation. Many of our judges attain extreme old age.

5. *Medical men*, from the general activity of their pursuits, their knowledge of the causes that promote health, and the wholesome exercise of mind and body induced by their profession, are generally considered as a long-lived class; but in this, as in other learned professions, small account is made of those who die before they have become known, of those who pine away from penury and hope deferred, or whom a desire to better their condition sends abroad to perish on inhospitable or pestilential shores. Yet, taking the whole together, the medical profession is certainly favourable to longevity.

6. *Schoolmasters, Clerks, &c.*, are subject to the usual diseases of sedentary persons, and to those produced by passing a great part of the day in vitiated air, with the sternum leaning on a desk. Such persons should live at some distance from the scene of their labours, that they may be compelled to take exercise in the open air.

7. These observations apply also to *Merchants*, to *Master-manufacturers*, and *Shopkeepers*. A British merchant has, when successful, an enviable life. The morning is dedicated to business, and the afternoon to his family and friends; while his home is usually remote from the crowded streets in which his counting-house is necessarily placed.

8. *The Shopman*, however, generally leads a very different life. He is late and early in the shop, the whole day is spent in serving customers, and in many instances his hours of rest are abridged by the duties of his business, which afford him no time to take exercise in the open air. This is peculiarly hard on young persons, perhaps sent from the country to be immersed in the smoky atmosphere of a crowded, narrow street. Multitudes of both sexes annually fall victims to this change.

9. *Soldiers and Sailors*, when they escape the perils of training to their laborious occupations, are often healthy, if temperate, and if care be taken of their health by their superiors. Their ailments often arise from their own intemperance, as much as from the casualties of their calling. Excessive fatigue is certainly unfavourable to longevity; and when we find very old persons in this class, we may attribute it in a great measure to the iron nature of their constitutions, which have enabled them to resist the hardships to which they must have been subjected in their younger years. Soldiers on duty are more exposed than sailors to wet and cold, to unwholesome climates, and to bad fare. A sailor carries with him his provisions and his change of raiment; and in the British navy he has much attention paid to his health while on board his ship. Long marches are apt to produce diseases of the hip joint, and hernia, especially in young soldiers. The sailor is liable also to hernia from strains in the course of his laborious duty.

10. *Agricultural Labourers* have generally a very healthy occupation. When the returns of their industry afford them sufficient aliment and comfortable clothing, their situation is much more favourable to health than that of the town mechanic. The same may be said of carters, postilions, and coachmen; except that the latter are often exposed at night to the inclemencies of the weather, and are not always remarkable for sobriety.

11. *Quarrymen and Stone-masons* are liable to serious injury from the minute dust they create entering the air passages along with their breath. This often gives rise to a species of consumption; and such persons are seldom long-lived. It affects the stone-masons of Scotland more than those of England: the former work under sheds, the latter in the open air. Marble-cutters for the same reason are unhealthy; and even the employment of a sculptor cannot be considered as a good one for a person of delicate lungs.

12. *Carpenters* and *Joiners* exercise healthy trades, because they require activity, and are freely exposed to the air in many of their operations. It is very different, however, with artizans whose trades are chiefly carried on in a vitiated atmosphere.

13. The trade of the *Weaver* is always rather unhealthy from his working in a confined space; but the introduction of machinery has reduced the pittance of the hand-loom weaver below what can support life with any comfort, and his habitation is proportionally wretched. There is in this occupation exercise to the limbs; but the breast leans against the beam, which, with wretched fare and depressed spirits, render the trade of the weaver unfavourable to health.

14. *Milliners and Tailors* are confined in hot and ill-ventilated rooms, they work too many hours in the day, and often have the natural hours of rest greatly abridged. Milliners are liable to become short-sighted; and the practice of biting the thread generally injures their front teeth. The lives of young females are often sacrificed to this business. Tailors assume a faulty position whilst at work; and the consequence is, that when they walk they have a peculiar strut; the increased power imparted to the muscles of the back, from long supporting the weight of the head, causes the shoulders to be preternaturally drawn back. They are also very subject to phthisis.

15. *Shoemakers* are more healthy; but the pressure of the *last* against the sternum and stomach is sometimes injurious.

16. *Miners and Well-sinkers* are engaged in laborious trades, in which they are exposed for considerable periods to breathe a vitiated atmosphere; and are further liable to the bad effects of inhaling dust, which predisposes to asthma.

17. Artizans working amidst *putrid animal matters* seem more liable to plague and typhoid fevers than most other classes.

18. Artizans exposed to inhale *minute particles of dust* are very liable to pectoral diseases. This is especially the case with knife and needle grinders. They are subject to the disease called *grinder's rot*, an incurable consumption, which renders this occupation most deadly. Currents of air, and interposed plates of glass, have been used to remedy this evil. Large magnets have been employed to arrest the iron dust, but it cannot abate that from the grindstone itself, which is not less fatal.

19. *Workers in lead, brass, and copper,* are subject to disease, from those substances finding their way into the system, as already stated.

20. *Bleachers and Dyers* are liable to suffer from acrid fumes, in some instances, and also from sudden changes of temperature.

21. *Snuffmakers and Millers* are exposed to dust; and the former to the consequences of inhaling also a narcotic; but the effect is seldom very marked on either.

22. *Chimney-Sweepers* are liable to consumption, and to a peculiar cutaneous disease, the *chimney-sweeper's cancer,* which chiefly affects the scrotum. Early excision removes it; but it is liable to recur.

23. *Cotton, silk, and flax spinning* by machinery expose the operatives to bad air, dust, and confinement in hot rooms. This is especially injurious to the young, who are much employed, from eight years and upwards, in such manufactories. The hours of work of all classes in them are too long. Woollen factories seem to be less unhealthy on the whole; but in them the employment of very young children, and too long hours of labour, are to be regretted.

24. *Persons exposed to a high temperature,* such as *Cooks, Confectioners, Bakers,* are liable to rheumatism, from sudden changes of temperature. Bakers were remarked to be the most general victims of the plague at Marseilles in the beginning of the last century. *Sugar-refiners* are exposed to much heat, and to sudden chills. *Smelters of iron* and other ores are subject to the same; to cough, from dust, especially if they be founders; and their eyes become weak, from the intense glare of the metal. *Glass-blowers* not only suffer from these causes, but also from the excessive exertions of their lungs, which often give rise to hæmoptysis and asthma.

SECTION II.—CIRCUMSTANCES AFFECTING THE HEALTH OF COMMUNITIES.

Climate.

I. CLIMATE.—The effect of climate, the most general of these circumstances, depends chiefly on the temperature, the hygrometric state of the air, and the general force and direction of the winds. The temperature of any place is well known to depend, in a great degree, on its latitude. The inclination of the earth's axis to the plane of its orbit has diffused the influence of the sun's rays more extensively over the surface than if the same points had always a vertical sun. The changes in temperature had been marked long before there was an instrument for measuring their extent, and hence the distribution of the earth's surface into parallel zones denominated *climates;* but the invention of the thermometer showed how ill this arrangement accorded with observation; and it was soon found that there were very different climates under the same parallels. The average or mean temperature is obtained by a series of thermometrical observations, carried on in the open air and in the shade. Large springs and deep caverns usually have the mean temperature of the place where they occur; and it has been found that a series of observations made every hour through April will give a pretty accurate mean temperature of that place for the whole year.

Temperature, however, is also considerably modified by longitude. Thus it is found that the mean temperature of any latitude in Western Europe is higher than that of the corresponding latitude in Eastern Asia, or in America, as may be seen by casting the eye over Humboldt's chart of isothermal lines. A comparison of similar observations indicated to Sir David Brewster that there were in each continent certain meridians on which the mean temperature is the lowest in that parallel. These he termed the *cold meridians,* in approaching to which the mean temperature falls on either hand.

But the principal circumstance which modifies the effect of latitude is elevation above the sea. As we ascend mountains, the temperature falls; and in every region, if its mountains be sufficiently lofty, they are the abodes of perpetual congelation. The limit varies with the latitude: it is highest under the equator, and diminishes as we approach the poles: thus, at the equator, the point of perpetual congelation is more than 15,000 feet above the sea; in Britain it is about 5000. The climate of a place, then, varies with the latitude, with the longitude, and with the elevation.

Even when the mean temperature is the same, places may differ greatly in the extremes of heat and cold in summer and in winter. The chief agent in equalizing heat is the ocean, the temperature of the mass of which remains nearly the same in all latitudes. This renders the summers of islands less hot, and their winters less cold, than that of continents under the same parallels. The peculiarities of climate affect the vegetable productions of a country, and its salubrity is greatly modified by the nature of its surface. A region shrouded in forests is generally colder than one exposed to the rays of the sun; and the exhalations from swamps and marshes materially affect its fitness as a residence for man. Such countries are subject to violent intermittent and remittent fevers, especially when the marshes are acted on by intense solar heat; and in tropical regions such places are pestilential. Several other diseases appear to depend on climate, as the *goitres* and *cretinism* of the Alps and other mountainous countries, the *elephantiasis* of Africa and the West Indies, and the strumous affections of cold climates.

All these peculiarities must be considered by those consulted on.

The sites of towns.

II. THE SITES FOR TOWNS AND HABITATIONS.—If the medical man be asked to give an opinion on any particular site, let him consider—

1. *The Purity and Hygrometric state of the Air.*—The average proportions of the cognisable ingredients of atmospheric air are,—

	Measure.	Weight.
Nitrogene	77·50	75·55
Oxygene	20·00	23·32
Carbonic acid	0·08	0·10
Aqueous vapour	1·42	1·03

The proportions of the gaseous ingredients are nearly the same everywhere; but the proportion of aqueous vapour varies greatly, according to the temperature and pressure of the atmosphere. It is the source of clouds, dew, fog, and rain, according to the suddenness of its precipitation. The quantity present in air may be estimated by Leslie's *hygrometer.* The quantity of rain which falls in any place should be ascertained by the *rain guage*; and the quickness of evaporation by experiment, or by observations with Leslie's *atmometer.* The number of rainy days should also be noted; for the quantity of rain is not proportional to the number of wet days. In hot climates it rains more seldom, but more falls than in temperate regions. Thus, the mean annual rain in the West Indies averages 120 inches; at Calcutta it is = 81; at Rome = 39; at Liverpool = 33; at Edinburgh = 24; at Petersburg = 16. In any climate, more rain falls in mountainous districts than in plains. Thus, 50 inches fall in Argyllshire; whilst at Glasgow the rain is about = 30; at Elgin = 24 inches.

The changes in barometric pressure should also be noted. These are extremely small within the tropics, or even in Southern Europe, but fluctuate in Northern Europe, even to $\frac{1}{10}$th of the whole column.

2. *A Supply of potable Water* is a most essential requisite. It should not be *hard,* it should be free of any peculiar taste or smell; and the nearer its specific gravity approaches 10002, to distilled water as 10000, so much the better.

Medical Police.

The capability of carrying water through pipes, to any station, is important, when a colony is to be founded. Running water of a good quality is also very important; but it should be recollected that stagnant water is not wholesome.

3. *Fuel* is another essential requisite, both for cooking and for warmth. A plentiful supply of wood, coal, or peat is indispensable where many human beings are to be congregated. Open fire places are cheerful, but not economical modes of warming apartments; stoves are more frugal; hot-air flues combine ventilation with warmth, but require considerable attention in their management; steam-tubes convey an equable temperature, but are less convenient than the circulation of hot water, in the apparatus devised by Mr Perkins.

4. *Vicinity of Trees* is an important circumstance; but it must not be forgotten that a station buried in deep forests is seldom wholesome, and in hot climates is often pestilential.

5. *Vicinity of Hills and Mountains* is also deserving of consideration. If they be very lofty, in hot climates, the plains at their feet are often pestilential, producing *black vomit* and *jungle fever;* yet removal to the mountains immediately relieves the sufferer, as is witnessed in the ascent from Vera Cruz to Xalapa, and from Southern Hindustan to the Neilgherries.

6. *Vicinity of Marshes*, in every country, is to be shunned in fixing on a site for human habitations. Marshes produce malignant remittents in hot seasons, and give rise to severe hepatic disease. The marsh fevers of Walchern, and the *malaria* of Italy, originate in stagnant water; and the fatality of some of our stations in the West and East Indies are to be attributed to swamps. Some of them, as British Guiana, have become more healthy as the country is more drained and cultivated.

7. *Vicinity of the Sea* is always an important element in choosing a station. In hot climates the sea-breeze mitigates the heat of day, and renders it endurable. This breeze in summer is very regular, even at Gibraltar. The vicinity of the sea also mitigates the cold of winter. Sometimes it renders a station unhealthy, when the recession of the tide exposes a great extent of a muddy beach. This is especially the case at the mouths of great rivers; yet such stations, though unwholesome, are often politically important as naval stations, or as keys to the back country. Marshes into which sea-water occasionally enters are observed to be more pestilential than mere fresh-water swamps.

Drains and sewers.

III. Drains and Sewers are important public works, on the proper construction of which the salubrity of a station may greatly depend. They should have such a fall as to carry off impurities, and to prevent an accumulation of stagnant water. The Greeks and Romans excelled in their attention to such works; but the unhealthiness of many places in Italy, in the present day, is owing to the neglect of those useful structures. Egg-shaped drains are the best.

Public ways.

IV. Paving of Streets, and Care of Public Ways, are objects also worthy of the attention of the medical man, though chiefly in the province of the civil engineer.

Cemeteries.

V. Cemeteries.—Little attention has been, in this part of Europe, bestowed on the police of repositories for the dead. Burial in churchyards, in the midst of a crowded population, and even within churches, is still suffered to disgrace our cities. The French have set a good example; and the Turks have been long noted for the decent propriety and judicious position of their cemeteries, which are always beyond their towns. The same is the practice of the Chinese, and of many nations whom we call barbarous. A better system has commenced among us, in the new cemeteries of Glasgow, Liverpool, Newcastle, Edinburgh, and London; and it is fervently to be hoped, that ere long our towns will cease to be infected with putrid emanations from crowded churchyards, and the temple of God to be polluted with the frail remains of mortality. The cemeteries in London are a disgrace to the metropolis; but the new cemeteries are at a good distance from the metropolis, and are remarkable for their elegance and appropriateness, especially those of Norwood and Kensal Green; while those on each side of Edinburgh are distinguished by their propriety and neatness. The best mode of sepulture is probably in the earth, without vaults; but anything is preferable to the horrid practice in Rome, of disposing of the carcases of the poor in huge caverns, often opening into the very churches.

Hospitals.

VI. Hospitals.—The erection of hospitals is intimately connected with the subject of medical police. We cannot enter on a consideration of each sort of hospital, but state in general terms, that the wards should be lofty, with windows on one side, and galleries on the other for exercise to convalescents. Ventilation should be secured by some of the means already indicated; the wards should be provided with privies, and baths appropriated to each; the bedsteads should be of iron, as less liable to harbour vermin; airing grounds and convalescent rooms should be attached to all hospitals. In a lunatic asylum, each class of patients should have separate airing grounds; and occupations suited to their cases should be provided for convalescents. Foundling hospitals, from the mortality in them, even under the best management, seem to be amongst the most pestilent institutions of mistaken benevolence. Such considerations induced a German author to propose as an appropriate inscription over the gates of such establishments, "Children murdered here at the public expense." Hospitals for the sick, military hospitals, and barracks, all may fall under medical police.

Schools.

VII. Schools.—Seminaries for the instruction of youth merit more attention from the legislature than they have received. The rooms are often defective in ventilation; and the modes of warming them in cold weather are often very inefficient. In some schools too little attention is paid to vary the diet of children; and though seldom deficient in quantity, at large public and private schools, there often exists inattention to render it palatable, or to suit it to peculiarities of constitution. In many schools the hours of study, for very young children, are too long. The degrading practice of public flogging, even almost to manhood, in some schools, is brutalizing to the inflictor, and destructive of the delicate sensibilities of ingenuous youth. We must also stamp with our strongest disapprobation the practice of *fagging*, which prevails at some English schools, and is calculated to foster the vices of both tyrants and slaves. In female seminaries the lessons are generally too long, the pupils too sedentary, too little in the open air; and many female *accomplishments*, as they are termed, are apt to produce lateral curvature of the spine, as was fully proved by the late Mr Shaw.

Prisons.

VIII. Prisons.—The state of our prisons is much improved since the time of Howard. The principal improvements are in the county prisons of England, in many of which much attention is paid to preserving the health of prisoners, by clean rooms, commodious airing-grounds, and humane regard to their diet, and the cleanliness of their persons. In most of the prisons of this country, however, much is still defective, in what relates to the classification of prisoners, and separating juvenile delinquents from hardened offenders. In the county jails of Lancashire and Cheshire much has been done to render prisons what they ought to be; but even in some of the best English prisons there are still no hospitals for the sick inmates; and the jails of Scotland are far behind those of the two counties alluded to in every respect. As far as lodging and diet go, there is no room for improvement in many British jails; and this humane attention is rewarded by the disappearance of jail-fever from our island. The subject of prison discipline is a wide field. The benevolent exertions of the late Mrs Fry and her Quaker associates prove that much good would flow from attention to the instruction and moral improvement of the unhappy inmates of our prisons.

Lazarettos.

IX. Lazarettos and Quarantine Establishments are of Italian origin, at the period when the commerce of the East was engrossed by the free cities of Italy. The doctrine of contagion is not of modern origin, as has been ignorantly alleged. Notwithstanding the clamour of interested individuals a few years ago, no rational medical man denies the contagious nature of the plague; and we have no doubt that the immunity of this island from that dreadful scourge for 170 years, notwithstanding our multiplied relations with the East, is mainly owing to the rigour with which the quarantine laws have been enforced. Some of these regulations may err on the side of excess of caution; but this is far preferable to rash experiments, prompted by crude medical speculations, and supported, as they were attempted to be, by distortion of facts. The quarantine laws were revised in 1825, and the code is now, upon the whole, good. The quarantine stations for Britain are Standgate Creek, Deal, Milford Haven, Liverpool, Holyloch in the Clyde, and Inverkeithing Bay in the Forth.

Punishments.

X. Punishments.—This subject, the last of the present dissertation, is worthy of the attention of the legislator and of the medical jurist.

1. *Corporal Punishments*, inflicted by sentences of our courts, extend to imprisonment, whipping, and forced labour.

Imprisonment is adjudged for several offences, and even for inability to pay a debt. When the health of a prisoner might suffer from confinement in a damp or unwholesome jail, the humanity of judges has frequently mitigated the severity of the sentence, on the representations of medical witnesses. It would be unjust to inflict a greater punishment than the law contemplated, by the mode of confinement; but in general our jails are far more comfortable as far as lodging and diet are concerned, than the usual habitations of the very poor; and therefore imprisonment, in some instances, may have lost some of its salutary terrors in preventing crime.

Whipping is sometimes inflicted by sentence of the court, either publicly or privately; it is now generally applied to juvenile offenders in prison, and is far less frequently inflicted in public than formerly, especially since the abolition of the pillory for ordinary crimes. Flogging is still permitted to a limited extent both in our army and the navy. A medical man is always by on such occasions; and should he declare the punishment *enough*, even one lash more at that time inflicted is a crime, and would subject the officer who ordered it to indictment for murder, should the sufferer die. *Hard labour* is now generally inflicted by the *tread-mill*, a contrivance by which the united weight of the prisoners condemned to it puts in motion a wheel, which moves machinery. The defect of this punishment is its inequality. To active persons, accustomed to walking, it is a light exercise; but to sedentary persons it is a most grievous punishment, giving intolerable pain to the muscles of the legs and the spine. To the disgrace of our country it has been inflicted on females. Their muscles are too weak, and their habits little inured to such labour; and it is liable to induce *prolapsus uteri*, or miscarriage, if the prisoner be pregnant; or serious diseases of the female system, in various ailments of the sex. It arms, too, with a dangerous and tyrannical power ignorant justices and unfeeling magistrates. The law should forbid this infliction on females in all cases, and prevent the erection of tread-mills in all prisons not liable to the legal inspection of grand juries, which it seems *houses of correction* in England are not, they being "not under the jurisdiction of the sheriff of a county." The beating of hemp was formerly with us the infliction for petty crimes; and in Holland it was rasping of dye-woods in the *Rasphaus*, which was always considered as a severe punishment. In America the penitentiary system of forced labour has been tried, and is still a subject of discussion. Solitary confinement has also been employed there, which some have considered worse than death.

2. *Capital Punishments.*—In this country, excepting in cases of nobles for treason, *hanging* is invariably the mode employed by law. This is with justice preferred to any other mode of public execution, as the evidence of those who have recovered after suspension renders it probable that the person suffers very little pain, from his becoming speedily insensible; and when the *drop* is employed, the injury to the neck seems generally to extinguish life instantaneously.

Beheading is in this country performed with the axe, in Germany with the sword, and in France with the guillotine; the prototype of which seems to be the Scottish *maiden*, still to be seen in the Antiquarian Society's Museum in Edinburgh. The axe often requires a repetition of the blow, and the sword is liable to the same objection. The maiden chopped off the head by the descent of an axe loaded with lead. The guillotine slices it off, entering one side of the neck by an oblique edge. All sorts of beheading present a very ghastly spectacle, and habituate to the sight of human blood; besides which, serious doubts have been started as to the possibility of the head for a short time retaining its sensibility.

3. *Pleas in bar of Execution.*—When a person is condemned to die, execution of the sentence may be deferred on three pleas.

Insanity may be pleaded by the relatives of the condemned, and a jury may be appointed to try the sanity or insanity of the prisoner.

The *youth* of the party is the second. There is no age fixed by British law at which the perpetrator may not be executed for heinous crimes. In 1629 a child between eight and nine years of age was executed in England for an atrocious murder; one of ten years was condemned in 1748 at York; and a boy of sixteen was executed in Edinburgh, in 1812, for a murder. Blackstone states the lowest degree of non-age, by the practice of the English courts, to be seven years.

Pregnancy is the last plea admitted in our courts. When this is alleged, a jury of matrons is appointed by the judge to inspect the party, and if the allegation be found true, she is respited till after delivery. These persons are very incompetent to so delicate a task. It should be intrusted to accoucheurs, who, from the appearance of the mammæ, and the application of the stethoscope to the abdomen in the latter months, will readily ascertain the truth or falsehood of the allegation.

(T. S. T.)

MEDICI, Family of, celebrated in the history of Florence and Tuscany during the fifteenth century, was one which, by its extraordinary industry and activity at a time when the Florentines extended their commerce over the known world, rose to be one of the first in the republic. This opulence secured to its members so great an influence in public affairs, that they became the most powerful and the most highly respected of the many citizens whose public virtues were such as free and popular governments alone can develop. It was through the sincere attachment of their ancestors to the more democratic party of the democratic republic of Florence, that the House of Medici, in after generations, acquired its extraordinary popularity. The origin of its influence may be traced to Giovanni de'

Medici, who in 1342 was in the service of Gauthier de Brienne, Duke of Athens, and tyrant of Florence. Gauthier having been chiefly indebted to him for the power he enjoyed, resolved to get rid of this obligation. Accordingly, under pretext that Giovanni had not with sufficient vigour defended Lucca against the Pisans, he caused him to be put to death. The Medici swore to be avenged, sided with the people, and by their powerful influence were chiefly instrumental in freeing their country from that tyrant. Soon after this the nobility, who had for fifty years been excluded from all share in public affairs, attempted to regain their ancient authority, but found a powerful opponent in Alamanno de' Medici, the head of the family, who called the people to arms, and finally expelled the nobles. Some time after, when the two factions of the Ricci and the Albizzi were struggling for power, this house, though not so strong, remained faithful to the people; and in 1360 Bartomoleo de' Medici, son of Alamanno, conspired against the Albizzi, who were at the head of the government. The conspiracy was discovered; but he escaped capital punishment through the protection of his brother Silvestro de' Medici, a man high in office and greatly esteemed. Silvestro further increased his popularity in 1378, when, having been appointed gonfalonière of justice, he thought it necessary, for the liberty of his country, to lower the authority of the Albizzi, and to raise the democratic party. After Silvestro's death, the aristocratic Albizzi having attempted to regain the power they had lost, the people revolted; and in 1393 chose Veri de' Medici, son of Silvestro, as their chief. This good citizen, however, instead of making himself master of the republic, as he could easily have done, modestly used his influence to calm the agitation and restore peace and unanimity. But the nobility did not fulfil their promises, and fearing the popularity of the Medici, banished the family of Silvestro from the republic. In 1397 one of them, Antonio de' Medici, having tried to get back to Florence, fell into the hands of his enemies, and was forthwith executed. Several conspiracies were attempted up to the year 1440, which effected nothing but the destruction of the more influential members of the family. The few who now remained in Florence were too insignificant to be suspected or feared. One of them, Giovanni de Bicci de' Medici, born 1360, belonged to a branch of the family that, either from want of genius, or from poverty, had never been distinguished in public life. Giovanni passed his youth in obscurity, became a small merchant, rose to be a third-class banker, and by constant application and prudent economy gradually improved his fortune. Having visited Bâle and Constance, where the famous councils were being held, he took advantage of the high rate of exchange, and greatly increased his wealth. On his return to Florence, where his name was dear to a people who still held Silvestro and Veri in grateful remembrance, Giovanni was regarded by all, from his wealth and wisdom, as well as from his firm traditional attachment to pure democracy, as the only man in the entire republic capable of putting an effective check upon the growing influence of the oligarchy. The Albizzi, still in power, reluctantly yielding to the popular feeling, accepted Giovanni as one of the priors of Florence in 1402, 1408, 1411. This new position in public life gradually restored the declining influence of the family of the Medici. Giovanni went as ambassador to Naples in 1406, was governor (*podestà*) of Pistoja in 1407, and was sent ambassador to Pope Alexander V. in 1409 to congratulate him on his elevation to the papal chair. In 1412 he went to the congress of Pietrasanta to settle the dispute with the Genoese, who would not suffer Portovenere to be given to the Florentines. In 1420 he was one of the deputies appointed to accompany to the confines of the state Martin V., who had just been elected at the council of Constance; and finally, in 1421, he became gonfalonière, and one of the ten who had to direct the war against Milan in 1423. He died in 1429, at the age of sixty-nine. From this Giovanni de Bicci descended that double line of the Medici who, till a very recent period, ruled over Florence and Tuscany. He left two sons, Cosmo and Lorenzo, the former of whom may be considered as the founder of the family's greatness. Cosmo de' Medici, born in 1389, and elected one of the priors of Florence in 1416, became at the death of his father leader of the Medicean party. A banker, like his ancestors, he followed their example in liberality and splendour. In his palace, one of the finest in the world, he assembled the artistic, the literary, the learned, and the scientific men of Italy. The Greeks who had left the fallen empire of Byzantium sought refuge under his hospitable roof, and found in him a generous patron. He collected ancient books and works of art from all parts, and greatly contributed to the revival of learning in Europe. Knowing that patronage is more indispensable for the progress of the fine arts than for that of literature, he rewarded artistic genius with the utmost munificence. He distributed his bounty with an unsparing hand, often advanced money without security, and when he knew his claim might be disputed, he did not ask for a return. By these means he gained immense popularity, and was enabled to become a formidable opponent to Rinaldo degli Albizzi, at that time head of the Florentine republic. Rinaldo thought it necessary for his own safety to get rid of him; and having in 1433 succeeded in obtaining as magistrates of the *Signoria* men who were of his party, he summoned Cosmo to the palace, and, among other things, accused him of having caused the failure of the war against Lucca. The sentence of death was about to be pronounced, when the gonfalonière, Bernardo Guadagni, bribed by Cosmo's friends, proposed that he and all his partizans should be exiled.

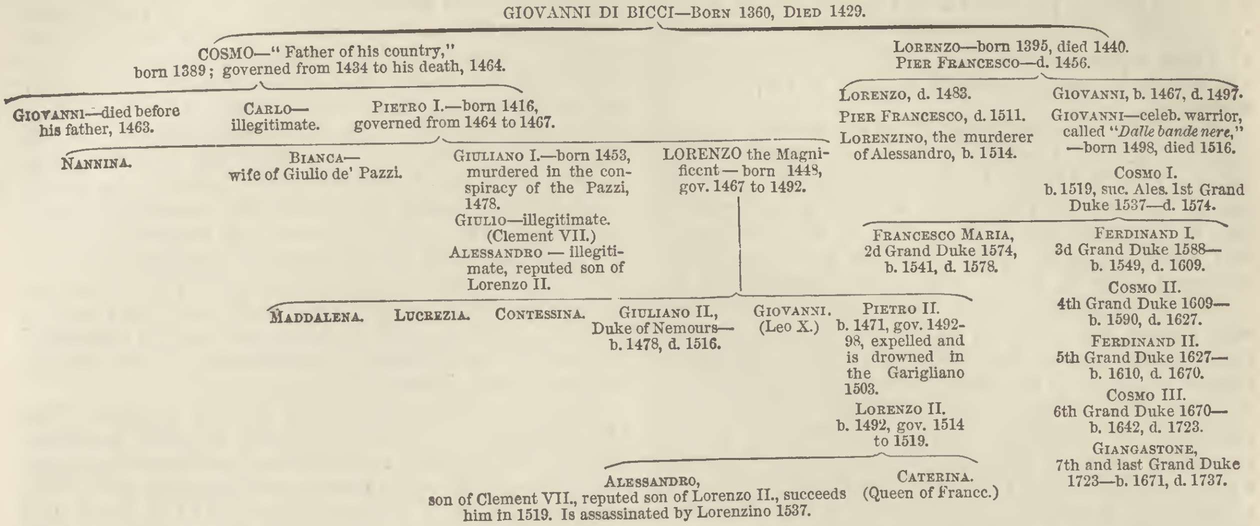
Cosmo retired to Venice, the ancient ally of Florence, and there, living in splendid exile, he built new palaces, gathered around him artists from all parts, collected books and manuscripts, employed learned men to correct them, and kept up a more active correspondence than ever with his friends and partizans both in and out of Florence. A year had scarcely passed, when, despite the exclusion of Cosmo's known friends from the ballot, the people elected a body of magistrates, or *Signoria*, less hostile to his family, by whom he was desired to return. Thus formally recalled, he triumphantly entered his native town, was enthusiastically received by the democratic party, and in 1434 intrusted by the priors to reorganize the state; while Rinaldo degli Albizzi and his friends were driven into exile. "This was a revolution," says Sismondi, "without bloodshed, but a revolution which laid the foundation of the Medicean tyranny, and sealed the death-warrant of the republic." After having ruled Florence for thirty years, he died in 1464, bequeathing his power to his eldest son Pietro. Cosmo was called by public decree the "Father of his country." His chief object, before his exile, was so to centre all the interests of Florence in himself, that he might become the soul of the political, monetary, commercial, artistic, literary, and scientific activity of his country. On his return, having defeated all rival factions, and assumed the supreme power, he thought Florence would never be tranquil, or maintain her ascendancy, so long as internal factions leagued themselves with neighbouring hostile potentates, who made party struggles subservient to their policy of repressing the Tuscan republic. The project he then formed of restraining the mutual jealousies of the Italian states by bringing them to a better understanding of their common interests, of making Tuscany the centre of a system of political equilibrium, or, in other words, making Florence the ruling power in Italy, while he himself was at head of affairs,—has been considered by some as Cosmo's principal title to political fame; while others more justly see in him the author of that centralization which, by destroying individual activity, prepared the way for the despotism of his descendants. He devoted himself very much to the study of Plato, whose philosophy he laboured to restore with all the energy he was accustomed to give to everything he undertook.

One of the most illustrious, if not the greatest member, of this family was LORENZO I., afterwards called the Magnificent, born in 1448 of Lucretia Tornabuoni and Pietro son of Cosmo. In 1467, when scarcely twenty years of age, he succeeded his father, a man of weak and irresolute character, who, during the short period of his government (1464 to 1467), had greatly impaired the popularity of the reigning family. Surrounded by false friends, who envied the greatness of the pretended democratic family, Pietro had not sufficient penetration to perceive his difficult situation, or the talent to make himself master of it. Seeing his patrimony had been greatly reduced by the prodigality of Cosmo, he, to regain wealth, and keep up the family influence, asked all the old debtors of Cosmo, which included a vast number of the people of Florence, to return the money which had been lent to them. Discontent, prosecution, conspiracy, and bloodshed were the only result of this policy; and on the death of Pietro, Lorenzo became heir to an inheritance of discontent and disaffection, which, if not speedily put down, was likely to prove fatal to his rising ambition. Lorenzo set to work with all the energy of a youth of twenty. His experience of state affairs dated as far back as Cosmo's death in 1464, when, at the age of sixteen, he had been often called upon to take part in important affairs in place of his infirm father. His youth induced the true friends of the Medici to associate with him his younger brother Giuliano. Having enjoyed the advantage of a first-rate education in literature, science, and philosophy, they learned early to imitate the literary and artistic munificence of their grandfather as well as his political wisdom. No sooner, however, had the two young brothers been placed at the head of the government, than the famous conspiracy of the Pazzi broke out, by which Giuliano lost his life in the church of Santa Reparata; while Lorenzo, although wounded, succeeded in saving himself by taking shelter in the sacristy. The people, who loved the Medici, put all the conspirators to death on the spot; "and more than sixty persons," writes Machiavelli, "either real or suspected accomplices, were executed by the infuriated mob, among whom was Francis Salviati, Archbishop of Pisa." Pope Sixtus IV., who seems to have encouraged the murderous attempt, and who was as much the avowed friend of the conspirators as the enemy of the Medici, exasperated at the ill success of the plot, excommunicated Lorenzo and the Florentines, under pretext that they had hanged the archbishop in his episcopal robes, and detained the Cardinal Riario in prison. Spiritual arms having proved ineffectual, he had recourse to temporal means, and by persuasion, exhortation, and menaces, induced some of the Italian potentates to raise an army against the Medici. Ferdinand, King of Naples, having become the principal ally of the pope, Lorenzo turned to France and Lombardy, and urged them to join him against the pope. The disasters experienced by the republic during the first campaigns only added to the excitement of the Florentines, who aided Lorenzo with the utmost enthusiasm. The evil, however, became too evident. Italy was about to become a battlefield, and civil progress would have been suspended, commerce and industry destroyed, the fortunes of the rising family endangered, if not annihilated, had not Lorenzo resolved by a bold and unprecedented act to extinguish the spark before it should burst forth into a flame. Without giving previous intimation, he set forth alone for Naples, and trusting to the faith of a noble adversary, put himself in the hands of his enemies. He went to the palace of King Ferdinand, and pled his cause in person, showing that the condition of Italy and the disposition of her princes and people were equally adverse to a general war; while the advantages of peace were as great as they were honourable. The king, struck with the ardour, eloquence, and political wisdom of the youth, not only consented to make peace, but immediately framed a treaty of mutual friendship between the two states (1479). The pope, thus left alone, was obliged to yield. Lorenzo returned to Florence, where he was looked upon with that respect which is the sure reward of successful daring. The policy of Cosmo now began to triumph: the influence of the Medici extended beyond the walls of Florence; their reputation became Italian; their preponderance was felt throughout the whole peninsula; and by their means the republic of Florence served to maintain a political equilibrum among the Italian states. The dream of Cosmo was thus realized by Lorenzo.

He now turned his attention to the arts of peace. Italian literature, which had shone with so much splendour through the genius of Dante, Petrarca, and Boccaccio, during the thirteenth century, had suddenly fallen into mediocrity and contempt. The study of Greek and Latin, which had been revived by the large-minded Cosmo, had perhaps tended to this injurious result. The *lingua volgare* was not yet considered noble; and no philosopher or scientific man could write his works in his native tongue. The learned language of the time was Latin, and all literary men, inspired by the example of Cosmo, gave their serious attention to its revival. Lorenzo, however, with a truer perception of the changes demanded by the progress of modern society, restored the Italian language to honour, wrote poetry in it himself, and led the way for Poliziano and Pulci, poets that will be read as long as the Italian language is known. He did not, however, neglect the classics; and he even vied with his grandfather in his zeal for collecting manuscripts and books; thus laying the foundation of the Laurentian Library, which, after all it has suffered from ruthless spoliation, is still the admiration of the world. Poliziano, in one of his letters, declares that Lorenzo used to say he would sell his furniture to buy new books, if he could not otherwise find means to do so. He sent Giovanni Lascaris, a learned Greek, twice to the East, at his own expense, to collect manuscripts. In addition to these services, this munificent patron of learning established schools in all parts of the Florentine republic, and founded the university of Pisa, from which were disseminated through Italy, and thence through the rest of Europe, that taste for art, science, and literature, which has done so much for modern European civilization. It was to him that Machiavelli dedicated his famous book *Il Principe*, and the celebrated secretary characterizes him as "eloquent and witty in discussion, wise in resolve, prompt and courageous in action." So great was the influence of Lorenzo's reputation, that he succeeded in causing his son Giovanni to be created cardinal at the age of thirteen, who became afterwards the celebrated Leo X.; and likewise put forward Giulio de' Medici, the illegitimate son of his unfortunate brother Giuliano, who became the no less celebrated Clement VII. Lorenzo died in 1492, at the age of fourty-four.

From Cosmo issued in direct succession the Dukes of Florence until 1537, when the Duke Alexander having been assassinated by Lorenzino, a descendant of the younger branch, the authority passed to that branch in Cosmo, who was the first of that series of grand dukes who ruled till 1737.

The Medici first gained absolute preponderance over the Florentine republic by their wealth, their patriotism, and their attachment to the democratic party. When their power was consolidated they became aristocratic, and finally upheld their authority by despotism and tyranny. Their influence having become, with Cosmo, a definite power, their history belongs to that of Italy and Tuscany. The following is the genealogical table of the two branches of the Medici family who governed till its extinction in 1737:—



GIOVANNI DI BICCI—Born 1360, Died 1429.
COSMO—"Father of his country," born 1389; governed from 1434 to his death, 1464.
Lorenzo—born 1395, died 1440.
Pier Francesco—d. 1456.
Giovanni—died before his father, 1463.
Carlo—illegitimate.
Pietro I.—born 1416, governed from 1464 to 1467.
Lorenzo, d. 1483.
Pier Francesco, d. 1511.
Lorenzino, the murderer of Alessandro, b. 1514.
Giovanni, b. 1467, d. 1497.
Giovanni—celeb. warrior, called "Dalle bande nere," —born 1498, died 1516.
Cosmo I. b. 1519, suc. Ales. 1st Grand Duke 1537—d. 1574.
Nannina.
Bianca—wife of Giulio de' Pazzi.
Giuliano I.—born 1453, murdered in the conspiracy of the Pazzi, 1478.
Giulio—illegitimate. (Clement VII.)
Alessandro — illegitimate, reputed son of Lorenzo II.
LORENZO the Magnificent — born 1448, gov. 1467 to 1492.
Francesco Maria, 2d Grand Duke 1574, b. 1541, d. 1578.
Ferdinand I. 3d Grand Duke 1588—b. 1549, d. 1609.
Cosmo II. 4th Grand Duke 1609—b. 1590, d. 1627.
Ferdinand II. 5th Grand Duke 1627—b. 1610, d. 1670.
Cosmo III. 6th Grand Duke 1670—b. 1642, d. 1723.
Giangastone, 7th and last Grand Duke 1723—b. 1671, d. 1737.
Maddalena.
Lucrezia.
Contessina.
Giuliano II., Duke of Nemours—b. 1478, d. 1516.
Giovanni. (Leo X.)
Pietro II. b. 1471, gov. 1492-98, expelled and is drowned in the Garigliano 1503.
Lorenzo II. b. 1492, gov. 1514 to 1519.
Alessandro, son of Clement VII., reputed son of Lorenzo II., succeeds him in 1519. Is assassinated by Lorenzino 1537.
Caterina. (Queen of Francc.)

Among the numerous works referring to this subject the following are the more important:—Nestor, *Histoire des Hommes Illustres de la Maison de Medici*, Paris, 1564; Ruby's *Discours de la Maison de Medici de Florence*, Lyon, 1604; Strozzi, *Della Famiglia Medici*, 1618; Ammirato, *Ritratti d' Uomini Illustri di Casa Medici del Ramo de' Duchi di Firenze e Granduchi di Toscana*; D'Aulberoche, *Eloges de Princes de la Famille de Medici*, Paris, 1627; J. M. Bruti, *Florentinæ Historiæ*, libri viii., Lyon, 1562; Varillas, *Les Anecdotes de Florence, ou l'Histoire Secrete de la Maison de Medici*, Haye, 1687; Varchi, *Storia delle Rivoluzioni di Firenze sotto i Medici*, Cologne, 1792; Bianchini, *De' Granduchi di Toscano di Real Casa Medici protettori delle Lettere e delle Belle Arti Ragionamenti Storici*, Venezia, 1741; Boissat, *Le Brillant de la Reyne, ou la Vie des Hommes Illustres du nom de Medici*, 1646; Galluzzi, *Storia del Granducato di Toscana sotto i Medici*, Firenze, 1781; Tenhove's *Memoirs of the House of Medici*, translated from the French by Sir C. Clayton, Bath, 1797. For the Life of Cosmo the Ancient, see Rozzi Silvano, *Vita di Cosimo de' Medici il piu vecchio*, Firenze; Maffei (Timoteo) *In Magnificentiæ Cosmi Medicei detractores libellus*, ibid.; Fabroni, *Magni Cosimi Medicei Vita*, Pisis, 1789, the best work on the subject; Cavalcanti, *Del Carcere, dell' ingiusto esiglio, e del trionfat ritorno di Cosimo Padre della Patria*, an old MS., published by the Canon Moreni, Firenze, 1821. For the Life of Lorenzo, Roscoe's *Life of Lorenzo de' Medici*, 2 vols. 4to, 1796, and the Italian translation of Milan, with many additions and corrections. *The Life and Pontificate of Leo X.*, by Roscoe, contains one of the most interesting accounts of the revival of letters and of the progress of the fine arts in our language, and has added much to our accurate knowledge of that important historical epoch (4 vols. quarto). See also Litta, *Famiglie Celebri Italiane*, Milano, 1832-38. (E. F.)

MEDICINE.

INTRODUCTION.

We propose to abandon the plan hitherto followed in previous editions when treating of Medicine, and to consider it rather as a branch of politics and of political economy, of singular interest to the citizen and statesman, than as a mere matter of science and art. It has a large encyclopædic literature of its own, to which our restricted space would not allow us to do justice in any degree. We propose, therefore, to give a general summary of the development and present condition of medicine and of the medical profession, with a more especial reference to their social and political relations. To this end we have traced their advancement and progress from the earliest period concurrently with fundamental changes in creeds and governments, so as to show under what conditions of society they rose and fell, and what their future development may be. The review is necessarily very general.

The term Medicine.

The word "Medicine," in its narrowest sense, signifies anything taken or applied by a person suffering from disease, with a view to relief or cure. Thus used, it expresses the *means* available in the art of healing. In a wider and philosophical sense it signifies all the *knowledge* applicable to the exercise of the art. This knowledge constitutes the science of medicine. Medicine is a term, therefore, which has a very varied and comprehensive signification, and includes every branch of medical science and every division of medical art. Practical psychology, surgery, midwifery, and pharmacy, and medical chemistry, botany, and zoology, are consequently departments of practical medicine.

Physic includes surgery.

Medicine, in this comprehensive sense, is synonymous with the Theory and Practice of Physic. By the 32d Henry VIII., cap. 40, § iii., the members of the London College of Physicians had expressly reserved to them the right to practise surgery. It runs as follows:—"And forasmuch as the science of physick doth comprehend and contain the knowledge of surgery as a special member of the same; therefore be it enacted, that any of the said company of physicians, &c., may, from time to time, as well within this city of London as elsewhere within this realm, practise and exercise the said science of physick in all and every her members and parts," &c.

Medicine the science of human nature.

When we examine in detail what is the knowledge that is necessary to this end, we find that it is, in fact, nothing less than a knowledge of the nature of man, and of its relations to all nature around him. Hence *physics*, the old term for the science of nature, was formerly synonymous with medical science, and the *physician* was but another name for the medical practitioner. This grand old name for the students of the science of human nature is so comprehensive, and so clearly indicates the duties and privileges of him who has to apply that science to the welfare of man, that it is to be hoped it will not be permitted to pass out of use, but, on the contrary, the physician shall henceforth be, as his name implies, able and fit for the practice of medicine "in all and every her members and parts."

First principles of medicine.

The physician looks at the human body as an artificer would look at a complicated piece of machinery, the construction of which is unknown to him, but which he has to keep and maintain in good working order, and, if possible, to render more perfect. He studies the preservation of the vital machinery in health, the restoration of it to health when disordered, and the development of it to greater perfection. These constitute the three great branches of medicine,—the prevention of disease, the cure of disease, the improved condition of man. Every man desires to enjoy and continue in life. Now, life is the continuous co-operation of those various organs which make up the body, and is enjoyed when they work harmoniously together. When this harmonious co-operation is interrupted, disorder or disease arises, and the vital functions are performed with pain, or at least languidly, imperfectly, and uneasily. It is one of the primary conditions or laws of life that the organism shall aim at the maintenance of the healthy or harmonious working of these various machines. The fulfilment of this condition has been attributed to variously designated powers, as—the vital principle, the archæus, the soul, instinct, the *vis conservatrix naturæ*, and the like. It is a law of existence common to all organisms, whether animal or vegetable, and is fulfilled by them all with little or no knowledge of the end of the law, or of the means by which it is attained. An infinite number of processes are going on in man, in fulfilment of this law, of which he is even yet wholly ignorant; and it is only by the most assiduous observation of the order of succession of vital phenomena and of their relation to various organs, that he has been enabled to determine in any degree the extent to which this law of existence is operative, and to learn the conditions under which it is fulfilled. It is by no means necessary to man's existence, when in health, that he should even know that he has organs. He is so little cognisant of the working of the brain as the organ of the mind, that to this day the greater number of mankind are practically of opinion that the soul can and does act independently of any organ whatever. As to the heart, lungs, stomach, and other viscera, it is a sign of perfect health when the man knows nothing whatever sensationally of their existence, and when their functions are performed wholly without his cognisance or aid. But these various organs are apt to be thrown out of gear. Then sensations are felt other than those of health, and a fundamental law comes into operation, in virtue of which the organism works to the beneficial object of repairing the disorder, and so removing those sensations. This is but a modification of that law of life in virtue of which the healthy action is maintained. The fulfilment of this law has therefore been attributed to the same forces; that is to say, to nature, the vital principle, an archæus, a *vis medicatrix naturæ*, *vis conservatrix naturæ*, &c. Nature appears to be the best of these terms, inasmuch as it more simply than others expresses the general law itself, without particularly specializing a subordinate agent. Nature, then, may be said to indicate what is necessary to be done in cases of disorder in the working of the viscera. If the disorder arises from mechanical causes, then in the lower animals—and in man when ignorant of medicine—the natural instruments or weapons are used for medicinal purposes. Thus the dog licks a wound it has received; the man covers it with his hand, supports the wounded limb, and the like. This is natural or instinctive surgery. *Surgery*, as a branch of medicine, includes the treatment of all mechanical injuries, together with all strictly external diseases, and the use of all mechanical or instrumental means of cure. *Medicine*, in its restricted sense, excludes these external diseases and remedial agents; as distinguished from the surgeon, and as a specialist, the physician neither treats them nor applies the remedies. His sphere of study is the great group of internal diseases, and their cure by drugs, together with the general principles of medical art—a knowledge as necessary, indeed, to the surgeon as to the physician. When, then, the cause of the disorder is not external, but within the organism,—that is, either in the fluids or the tissues of the body,—an attempt is equally made by nature to remove it. Now, noxious agents are formed within the organism during the natural processes, but in the state of health they are eliminated as rapidly as they are formed, constituting the secretions. If they are not eliminated, but accumulate in the organism, they cause disorder and disease. Again, noxious agents may be received from without (such as poisons, irritants, &c.), and these will generally operate in like manner as the retained secretions. In either case nature seeks the restoration to health by attempts at elimination or removal. These are often of a painful character, as coughing, vomiting, purging, and similar processes. It was considerations like these that induced the most distinguished physicians the world has ever seen to look upon the phenomena of disease as results of the efforts of nature. *Νουσων φύσιες ἰητροι*, is the pithy remark of Hippocrates—"Our natures are the physicians of our diseases." Sydenham (often designated the modern Hippocrates) adopted and promulgated the same theory. It has also been made the basis of modern systems of practical medicine. Unfortunately, the theory is only true in part; it applies strictly to individuals passing from a state of health to a state of disease, and who are living under the natural conditions favourable to health and to the exercise of the restorative powers of nature. But civilized men are surrounded by circumstances adverse to healthy function or structure; are in a large proportion not strictly healthy; and are therefore in a condition of body unfavourable to the exercise of the natural restorative powers, so that these natural efforts at cure are usually more or less imperfect. Nor even in the healthy is it a process to be implicitly trusted, for in them a temporary functional disease of an important organ may embarrass the action of other organs, and lay the foundation of chronic disease; and thus, if not arrested at the outset, may render nature's efforts more or less incompetent to restore to health. Medicine, then, seeks to know the natural processes, or physiology, so as to determine when the aid of art may be limited, or when it may be fully used.

CHAPTER I.—ANCIENT MEDICINE.

SECTION I.—ORIGIN OF MEDICAL SCIENCE AND ART.

Instinctive Medicine.

Origin of medical art.

Instinctive Medicine.

A knowledge of the conditions of health and of the curative uses of drugs is instinctive. Both the dog and the cat take remedies when ill; the dog, in particular, selects a certain grass and eats it medicinally. In the Greek mythology we find that a shepherd (Melampus) discovered the use of white hellebore by noticing that his goats purged themselves by eating it. He applied it to the cure of the daughters of Prætus, who, having taken vows of celibacy, appear to have become hysterical and monomaniacal. Bees apparently display in their political arrangements a knowledge of the laws of health, or of public hygiene. They ventilate their hives by a process admirably adapted to the desired end; they inclose dead animals which they cannot remove from the hive in hermetically sealed coffins.

In man a simple reason takes the place of the instinct in the lower animals. Thus, if he is nauseated, he thinks he will be easier if he could vomit, and accordingly looks about for some means to fulfil his purpose. The historians of medicine have found it necessary to go back for its origin to a very early period in the history of mankind; but this seems hardly necessary to the philosophical inquirer, because modern society, and the most highly civilized races, present the science and art in every stage of development.

An unlettered peasantry, remote from towns, and without a resident clergyman or practitioner, exhibits the practice of the art in all its simplest and primary forms. The sick rely upon their own experience or upon that of their neighbour, of whom one may be more sagacious or more pretentious than the rest. To this experience are added traditional medical knowledge of unknown origin, a belief in occult and mysterious agencies for evil and for good, a superstitious dread and worship of those agencies, and therewith superstitious practices and remedies. The "wise man" of the Christian village is a witch-finder, a meteorologist knowing in storms and strange appearances, a herbalist, a cunning trader on the superstition and ignorance of the people, and not without power to compel obedience to his commands. Many such still exist in every part of civilized Europe, as they have existed everywhere from the remotest history of society.

Origin of Scientific Medicine, and of a Medical Profession.

Natural development of medicine.

The development of scientific medicine, and of a medical profession, always takes place through successive phases. The simplest form of medical art readily passes into the patriarchal, in which the head of the tribe or community is the healer of disease and the depositary of all power. To this, in a more developed state of society, succeeds the sacerdotal, in which the heads of the people bear predominantly a sacred character. Out of the sacerdotal body next arises a distinct professional body, separate from it, and therewith a distinct science of medicine; and then, as the latter is developed, antagonism and conflict takes place between them. Next society passes into the phase of high civilization, and finally falls under the power of the military hierarchy. Concurrently with this change, religion, civilization, science, and medicine decay, to rise again from a renovated society. We have glimpses of this succession of phases from an early period of history. The earliest historical development of scientific medicine is everywhere traced from a priesthood, and the development of a priesthood to that combination of mental qualities and duties exhibited in the village *magos*. The "medicine man" of the Indian tribes in North America indicates what must have been the germ of the great sacerdotal caste which ruled so long and so powerfully the great nations of the east. Politics and law, religion and science, and (in close connection with religion and science) medicine, both as a science and an art, were all in the hands of the priesthood. This is the stage in human society of sacerdotal predominance. To this union of the priest, lawgiver, and physician, we owe that remarkable remnant of medical science found in the Mosaic writings—the system of public and domestic hygiene established amongst the Hebrews on a religious basis, and manifesting a very practical knowledge of various diseases and their origin. Learned as Moses was in all the knowledge of the Egyptians, it is more than probable that his system, in all essential details, was a reflection of the Egyptian doctrines and polity. Seventeen hundred years before the birth of Christ, Joseph commanded "his servants, the physicians," to embalm his father; a command sufficiently indicative of chemical science. Recent researches into the natural history of parasitic animals—the *Entozoa*—have rendered it probable that the Mosaic laws regarding clean and unclean animals had a foundation in a knowledge of these organisms—their nature, habitats, and the diseases they induced. We also get glimpses of the medical knowledge of the Egyptians in the older Greek authors. In the fourth book of the *Odyssey*, mention is made of Jove-descended Helen putting into wine a drug "that frees men from grief and from anger, and causes oblivion of all ills." This and other excellent drugs were given to her by the wife of Thone, "an Egyptian; where the bounteous land produces very many drugs; many excellent when mingled, and many fatal; and each physician is skilled above all men."

Early Egyptian medicine.

The cultivation of science could only be carried on through records of observation and experience. It was amongst the priesthood that writing arose and was first practised. Medicine, as an important branch of natural science, was necessarily a constituent element of the hieroglyphical or sacred literature, and was studied by the priests and priest-kings with ardour and success. Samuel was the chief of a school of prophets or *magoi*-priests; Solomon, King of Israel, was a great botanist, zoologist, and pharmaceutist, as well as pontiff, ruler, legislator, and moral philosopher.

Origin of a Medical Profession and Medical Literature in Asia.

Early Asiatic medicine.

The Levites, or sacerdotal caste of the Hebrews, appear to have practised medicine exclusively in the earlier period of the Jewish nation. To what extent the books of Hermes are authentic and ancient admits of question; but there is no question that the sacerdotal or hierarchical division of the people into castes extended over the whole of Asia, as well as through Egypt, during the earliest periods of civilization, and that the study of philosophy and the practice of medicine passed into the hands of a subdivision of the priestly caste, and thus the profession arose. The *Ayur Veda* appears to be the most ancient of the Hindu sacerdotal medical writings. Its date has been fixed at not later than the fourteenth century before Christ—that is, 900 years anterior to Hippocrates; but it appears to have been nothing more than a summary or abridgment by professional writers of still more ancient medical doctrines and practice. It contained eight divisions. The first two were surgical, including obstetric surgery; the third contained general pathology and the practice of physic; the fourth, pyschological medicine, or the treatment of insanity, founded on the theory of demoniacal possession, so prevalent throughout the east amongst all nations; the fifth treated of the cure of infantile diseases or prædiatrics; the sixth was devoted to toxicology; the seventh to personal hygiene and metallurgical chemistry; and the eighth to the diseases of the generative functions. The medical caste (*Vaidya*) amongst the Hindus received their designation from this ancient work—the term meaning one who understands the *Vidya*,—*i.e.*, the *Ayur Veda*. Besides the matters detailed, this ancient Veda contained anatomy, systematic general pathology, materia medica, and therapeutic hygiene. The ancient Hindu philosophers who lived subsequently to this work were termed *Rishis;* they also appear to have been a distinct body or college of commentators on the *Ayur Veda*, and teachers of philosophy and medicine. The *Charaka*, an ancient Hindu cyclopædia of medicine, was written by one of them; it is in the form of a dialogue. Another ancient standard work of this kind is the *Sushruta*. It is also a commentary on the *Ayur Veda*, but treats more especially of surgery, in addition to other branches of medicine. The *Rishis* were peripatetic lecturers on medicine; they also travelled about, like the ambulant physicians of Greece, curing diseases, and illustrating the influence of customs, manners, climate, and the like, on health. Their pupils went with them and took notes of their lectures. Many of these, in the form of compilations, are still in existence.[1] Hindu medicine has been stationary or degenerate for a lengthened period. Its origin is wholly lost in a remote antiquity.

The Ayur Veda. 1400 B.C.

Hindu medical profession.

SECTION II.—ORIGIN AND DEVELOPMENT OF ANCIENT EUROPEAN MEDICINE.

European Medicine in Greece.

Ancient European medicine.

European medicine dates as to its literature from the time of Hippocrates. The Hippocratic writings constitute a very complete summary of medical doctrines and practice as they were taught in Greece about 500 years B.C. The origin of Greek medicine and medical literature is as mythical to us as the origin of the *Ayur Veda* is to the Hindus. The first founders of it are also equally mythological personages. Chiron evidently corresponded to the Brahmans and to the priests of Egypt in his knowledge, and to the ascetic *Rishis* of the Hindus in his life and conduct. The myth is, that he held a school of physics in a grotto in Thessaly, and taught philosophy, music (or the principles of art), astronomy, the military art, political science, and medicine. A majority of the Argonautic heroes, and of the commanders at the siege of Troy, are represented as having been his pupils. Hercules and Æsculapius are also mentioned amongst the number. It is probable that the name indicates an ancient learned class, or incorporated body of professional teachers, rather than an individual, and points especially to the science and practice of surgery; for Chiron was celebrated for his surgery, as were his pupils. Hermes, like Chiron, was a mythical personage; and the books which bore his name in ancient Egypt are believed to express nothing more than the literature of the sacerdotal or learned corporations of Egypt. Sanchoniathon, the name of another author of this class, it is said, is a Phœnician word which signified a *magus* (philosopher or priest). The Phœnician writings that go under that name date probably from the age of the *Ayur Veda*. Whatever Chiron may have been, his successor Æsculapius was certainly already a purely mythical person in the time of Plato, and probably for 800 years previously.

Sacerdotal stage of Greek medicine. 1200 B.C.

The sacerdotal period of Greek medicine commences in the twelfth century B.C. with the erection of a temple to Æsculapius, about fifty years after the Trojan war. These were shortly multiplied throughout the then civilized world, and the priests were designated Asclepiadæ, or descendants of Æsculapius. They were in all particulars a sacerdotal medical caste. Their method of treatment being carried on in the temples, comprised all the essential elements of modern systems of empirical medicine. They had hydropathic establishments situated at or near thermal springs or fountains of living water, or upon the sea-coast, or amidst beautiful mountain scenery. Diversion of the mind, exercise of the body, regulated diet and regimen, friction and inunction of the skin, sea-bathing, mineral baths, and waters,—these and similar agencies constituted their remedial means. Besides these, they acted upon the imaginations of their patients by nocturnal religious solemnities and illusions of an impressive character, performed within the sacred precincts of the temple. Modern mesmeric processes and false miracles are, in some of the details, analogous to these, and wholly so as to the general principle upon which the method of treatment is founded. These delusions of the imagination were made subjects of ridicule amongst the Greeks at a later period of national culture. Aristophanes, in one of his comedies, puts an absurd description of the whole affair into the mouth of one of the characters who had been a patient. "The priests of the temple of Æsculapius," he says, "after having extinguished all the lights, told us to go to sleep, adding, that if any one should hear a hissing, which indicated the arrival of the god, he should not move in the slightest manner. So we all laid down without making any noise; but I could not sleep, because the odour of an excellent broth that an old woman held near me agreeably excited my olfactories. Desiring most ardently to slide along to it, I raised my head very quietly, and saw the sacristan going the round of the altars, take away the figs and cakes from the sacred tables, and put into a sack everything that he could find. I believed that I had a right to follow his example, so I rose up to go to the old woman's pot."

Origin of a lay Greek profession, and stage of conflict with Sacerdotal power.

Origin of lay Greek profession. 500 B.C.

These temples of Æsculapius being hospitals, were also the medical schools of the time. History has preserved the memory of four of the most celebrated;—that of Rhodes was the most ancient, and was already extinct at the time of Hippocrates; that of Epidaurus was consulted by the Romans; the school of Cnidos originated a small treatise of practical aphorisms—the *Cnidian Sentences;* and that of Cos gave birth to Hippocrates. It was at this school that the greater number of the Hippocratic treatises were commenced, if not written, although some are doubtless of a subsequent period. The appearance of these treatises therefore indicates one of those epochs in science, like that of Sanchoniathon and the *Ayur Veda*, in which the accumulated knowledge of a people is re-cast and digested by professional men. It was the age of Pericles,—that age in which the Greeks attained to so high a position both in arts, war, and philosophy,—the age when Socrates brought moral philosophy so near to Christian truth, and when natural history, logic, and metaphysics received a definite culture. The whole period during which the Hippocratic writings appeared extends, in fact, from the time of Pythagoras, about 500 B.C., to the death of Aristotle, 322 B.C.

Greek science in conflict with sacerdotal power. 500–300 B.C.

This advance in Greek philosophy and science appears to be mainly due to Pythagoras in the first instance, who, having studied philosophy and medicine in the then existing schools of Egypt, Phœnicia, Chaldea, and India, returned with an ample knowledge of Hindu, Chaldean, and Egyptian science and philosophy. From the fragments that are left, we may conclude that the philosophy and system of teaching of the Brahmans was that which he adopted. His philosophical views as to the transmigration of souls, his novitiate, code of morals, rules of abstinence, temperance, and purity of person and conduct, are very similar. He also, like the ancient *Rishis*, travelled from town to town as a teacher or lecturer, and established communities, apparently of a monastic character, in the principal cities of Magna Græcia. Pythagoras seems to have been contemporary with Confucius, the great reformer of religion and morals amongst the Chinese, and to have closely resembled him in essential particulars. But Pythagoras and his followers were not so successful in politics as the Chinese reformers. So soon as they interfered with the established religion and governments, they became obnoxious to the priesthood and to the tyrants who governed through them; so that the Pythagorean communities were broken up, and not a few of the sect were driven into exile or put to death. The life, trial, and death of Socrates may be taken as an example and illustration of the conduct, moral philosophy, religion, and fate of the followers of Pythagoras. Science had departed from the priesthood, and was already in antagonism to it. The diviners, soothsayers, and augurs,—the pontiffs and priests, with their idols, temples, omens, and oracles, were but the participants or agents of the ruling power in the state. The natural science they possessed was mainly used as an instrument for deceiving the multitude in various ways, as by simulating the miraculous, imitating thunder and lightning, contriving the flight of birds on this side or on that—in the east or in the west. With these men the earnest seekers after truth, as well religious as physical, came necessarily into conflict; and we have enough of the history of those times remaining to judge of the result. The palmy days of the ancient Greek republics were analogous in this, as in other particulars, to the era

Analogy of ancient Greek and modern Italian States.

of the modern Italian republics. A degenerate priesthood, rich in temples and lands, and possessing the secret springs of political power, held an almost undisputed sway over the unlettered populace, just as in the period of the Reformation. Equally at both periods they had become the mere exponents of hero-worship, and reflected nothing better than the vices and superstitious traditions of a sensual and ignorant people. Votive tablets were hung up in the ancient temples by the populace, expressive of their gratitude to a deified hero for medical aid afforded, just as had been done for many centuries previously in Egypt and India, and just as has been done for many centuries past in Europe in the temples of a similarly degenerate Christian period. Strange it is to see a medical superstition like this maintaining its hold upon man, and encouraged by the priesthood, through a long succession of vicissitudes, from the earliest dawn of Babylonian and Egyptian history to the latest day of the nineteenth century. And when Galileo, like Pythagoras, developed a truer system of the universe, the dominant sacerdotal body repelled it as being fatally opposed to their traditions, and persecuted the author. We shall find that in successive eras of man's history a similar antagonism between philosophy and traditional theology,—between scientific truth and the corruptions of revealed truth,—was developed. Nay, it is far from improbable that now, in the nineteenth century, we are on the very verge of a similar conflict.

SECTION III.—RISE OF THE ALEXANDRIAN SCHOOL.

The Military Power predominant in Greece.—Decline of Greek Medical Culture.

Decline of Greek medical culture. B.C. 336.

The wars which filled up the life of Alexander, the conqueror of Greece and Asia, interrupted the progress of science and philosophy in Greece. With the loss of freedom national culture became debased, and science was trampled under the feet of a cruel military superstition. Hero-worship attained its highest development in the assumption of divinity by Alexander, who outraged science in the person of Callisthenes, his friend and fellow-student under Aristotle, and whom he put to a death of torture for refusing to fall prostrate before him. But after his death science soon reared its head again in Egypt, in that city to which Alexander had given his own name. Two of his lieutenants and successors (Eumenes and Ptolemy) became its firm friends, emancipated it from the control of a corrupt religion and an effete priesthood, and gave its cultivators protection and a home. Pergamos was already celebrated for its temple of Æsculapius, and as a school of medicine. Here Eumenes collected in a large library all the recorded knowledge of the times. It was from this school, more than four hundred years later, that Galen sprung.

Pergamos. 263 B.C.

Rise of the Alexandrian school. 332 B.C.

Ptolemy Lagos, the uterine brother of Alexander the Great, rivalled Eumenes in his endeavours to advance science and art. He had already interested himself in the philosophy of India, where he had witnessed the self-immolation of an Indian *magus*. When he ascended the Greek throne of Egypt, he endeavoured to systematize the vast erudition that had been accumulating for many centuries throughout the civilized world, to utilize it, and to advance all branches of knowledge. It was this spirit that produced the Septuagint. His son Ptolemy Philadelphus not only gathered together all the written science and literature within his reach, and so founded that great library of Alexandria which survived the political vicissitudes of more than nine centuries, but he also invited to, and encouraged learned men at Alexandria from every quarter of the world, irrespective of creed or race.

This era was another of those epochs at which the human mind stops to take an estimate of its knowledge, and to lay the foundation for a new superstructure. Medicine participated in the general impulse given to science; but its greatest advancement was due to the establishment of schools of practical anatomy, and the cultivation of natural history, the materia medica, and pharmacy. Alexandria became so distinguished as a school of medicine that, in the time of Galen (nearly five hundred years after its foundation) a physician had a certain reputation already simply from having studied there. Almost all the distinguished physicians of the time were from the school of Alexandria.

Herophilus. 285 B.C.

Herophilus was the principal connecting link between the Greek and Alexandrian schools. He was born at Chalcedon (not at Carthage, as some writers state), a small town in Bythinia, and studied medicine at Cos under Praxagoras, the last of the Asclepiadæ, and the successor to Hippocrates. Having completed his studies, he went to Alexandria, where he reduced the dislocated shoulder of Diodorus Siculus, one of the many learned men which Ptolemy Philadelphus had gathered around him. He was an attractive public teacher, and wrote a learned, complete, and highly-esteemed theory and practice of medicine, of which, unfortunately, only fragmentary notices and extracts remain. But his chief merit was his indefatigable anatomical and physiological researches. Aristotle had already prepared the way for a great advance in human anatomy and physiology by his investigations in comparative anatomy and physiology, of which he laid the foundations. Hence, when the Alexandrian school carried their inquiries into human anatomy and physiology by careful dissection and experiments, they had their labours rendered much easier by this important advance. So extensive and comprehensive were these researches, that Herophilus may be declared with entire justice to be the founder of scientific anatomy and physiology. To him is due the great discovery of the anatomy of the nervous system, and the fundamental principles of neurology. Plato and Aristotle hardly knew that there were nerves; Herophilus demonstrated the functions of both the motor and sensitive. The anatomy of the brain and spinal cord was also much advanced by him; and it is pleasant to know that his name still sounds in the ear of the medical student when the position of the *torcular Herophili* is demonstrated to him. He it was who fixed the seat of thought in the brain, and more especially in the fourth ventricle. Herophilus would have been more successful if he had been free from the trammels of philosophical and religious dogmas; for it is evident that, like many original investigators, he attempted to square his researches with the established creeds of the day. Thus, although he placed the seat of the intellect or of thought in the brain, he made it only one of four forces, the other three being seated in the liver (the nutrient), the heart (the preserving), and the nerves (the sentient or feeling). In this he followed Plato and Aristotle. His great practical contribution to science was an elaborate doctrine of the pulse, which seems to have become part of the Chinese system of medicine, and is still extant in China.

Erasistratus. 260 B.C.

Erasistratus was the contemporary of Herophilus, and, like him, was a light of the Alexandrian school. He was a practical anatomist, a skilful and bold surgeon, and a good physician. He was sparing in the use of the lancet or of powerful remedies, preferring abstinence and rest. He introduced chicory into practice for hepatic affections.

Serapion. 235 B.C.

Serapion, the head of the sect of empirical practitioners, was also of the Alexandrian school, and lived about fifty years after Herophilus and Erasistratus. To this sect belonged also Heraclides of Tarentum, who advanced general pathology and the practice of medicine, materia medica, pharmacy, and surgery. After his death toxicology had special attention. Mithridates, King of Pontus, has connected his name with a composition (a theriaca), which he prescribed as an antidote to poisons. The fact is a significant comment on the uses to which an improved knowledge of materia medica and pharmacy were then (as now) put. Elaborate pharmaceutical compounds characterized the second century before Christ. The *Theriaca* and *Alexipharmaca* of Nicander of Colophon, are two of the few works of this era which have come down to us. The formula for the Damocratic confection, invented by Damocrates, a contemporary of Nicander, contains forty-four ingredients. It was given in the Pharmacopœia of the College of Physicians of London, published in 1746, together with others of the same period. The Philenium (a sedative compound containing opium as the efficient ingredient) was one of these; it bore the name of Herennius Philo, a native of Tarsus, the metropolis of Cilicia.

State of medicine 321–100 B.C.

During the period intervening between the death of Alexander the Great and the first century before Christ, medicine had hardly taken root in Rome. It was studied principally in Greece, Asia Minor, Egypt, and Magna Græcia, or Southern Italy, where medical schools abounded. Some of the family of Herophilus appear to have founded a medical school at Laodicea, a city that at the time carried on a lucrative commerce, especially in wines, with Alexandria, and another at Smyrna. These seem to have been termed Herophilian.

We have nothing but fragments of the medical works which emanated from the Greek school of Alexandria prior to the Roman conquest. There is reason to think, however, that the prejudices of the people sooner or later threw obstacles in the way of the practical anatomist, and that thereupon succeeded a period of speculation and decline. This most probably began anteriorly to the Roman conquest and the burning of the great library by Julius Cæsar. Cleopatra undoubtedly carried out the philosophical traditions derived from her predecessors the Greek kings, and endeavoured to replace the loss of the library by substituting that of Pergamos, which she solicited as a gift from Mark Antony. The measure served to maintain the reputation of Alexandria as a great school of philosophy, medicine, and science generally; but the ancient religion was become effete; the Roman arms triumphed everywhere, and the metropolis of the world was next to become the centre of science as well as of government, to which the great Greek schools became merely tributaries.

SECTION IV.—ORIGIN AND DEVELOPMENT OF MEDICINE IN THE ROMAN EMPIRE.

The Patriarchal and Sacerdotal Stage of Roman Medicine.

Medicine in Rome—its patriarchal and sacerdotal stage. B.C. 750–200.

The Romans (if the early annals of the city may be trusted) were warlike agriculturists,—not civilized, yet not barbarous,—being in close intercourse with the cities of the great Etrurian confederacy, and of Magna Græcia, in which scientific culture and the arts attained to as high a development as in Greece itself. Medicine, nevertheless, passed through its successive stages of development in the Imperial city.

The Roman national mind, when fully developed, was essentially political and military; it had little sympathy for science or philosophy. The Roman people were content to be without native physicians for nearly five centuries after the foundation of the city. The elder Cato (about 200 B.C.) practised patriarchal medicine when the Greek schools were in their glory, and was himself the physician of both his household and his domestic animals. It is said, indeed, that his unskilful treatment proved fatal to his wife. Cabbage was one of his most reliable remedies; and the magical words he used for the reduction of luxations and fractures are still extant. With him this patriarchal medicine was a matter of principle, or perhaps more correctly, of pride and ignorance. He hated the medical profession. He pretended to believe that the Greeks had sworn among themselves to kill all barbarians (and to the Greeks the Romans were eminently of that class) by means of drugs. He was indignant at the imputation of barbarism. He was a type of a dominant but ignorant class still plentiful in the world. His haughty temper could not brook superior knowledge, or the claims to it. As he detested the people, so he detested the philosophers, rhetoricians, and physicians, of Greece; he accused them of corrupting the Roman people, and at last succeeded in obtaining a decree for their expulsion. Nevertheless the physicians were exempt. Two hundred and fifty years later Pliny exhibited similar national prejudices against Greek science and literature, although his *Materia Medica* was almost wholly copied from Greek writers. Like Cato, he denounced all foreign, that is Greek physicians.

It was when the increasingly numerous population of the city of Rome was seriously diminished by a pestilential disease, about 187 B.C., that the Romans first appear as showing an interest in medicine. On that occasion, in accordance with their superstitious prejudices, a deputation of six went in quest of advice to the great Æsculapian temple and medical school at Epidaurus, when (according to the legend) they appropriately received one of the sacred serpents to take home with them, that they might build a temple to the god where the animal chanced to go ashore. This temple was duly erected, but it does not seem to have secured the usual results, that is, the establishment of a college of sacerdotal physicians. Yet it is hardly probable that sacerdotal medicine was not practised. The Etrurians possessed a knowledge of the physical sciences, and were the engineers of the day; they were also the metallurgists, chemists, and manufacturers, and they supplied augurs and a knowledge of augury to the Romans. We may conclude, therefore, that from the Etrurians sacerdotal medicine was also introduced into Rome.

Origin of a Medical Profession and Medical Literature in Rome.

Roman medical profession and literature. B.C. 200.

When medicine became a separate profession in Rome, the members did not arise out of the sacerdotal class, as in Asia and Greece. The *Medici* of the Romans were at first chiefly, if not exclusively, slaves or freedmen, the prisoners of war captured in their campaigns against the nations of the then civilized world. The first purely professional man seems to have been a Greek named Archagathus, upon whom, according to Pliny, the senate conferred the freedom of the city, purchasing for him also a shop and surgery in the Acilian Causeway. In proportion as the Roman empire extended over the flourishing and refined cities of Sicily, Greece, Asia Minor, and Egypt, Rome became cosmopolitan, and consequently attracted to it from every quarter the ambitious intellects of the day. One of these was Asclepiades, a native of Prusa in Bythinia, who having studied at Alexandria and Athens, established himself as a teacher of rhetoric at Rome, about the year 90 B.C. The Greek language and literature were then cultivated by the Roman nobility and gentry, for it was the fashion amongst them to send their sons to study at the great seats of science in Greece. These, when they returned to Rome, welcomed Greek professional and literary men to their city, and to their personal friendship. Asclepiades had the honour of Cicero's intimacy, and of that of other illustrious men of the day. He abandoned rhetoric for the practice of medicine, and, like all characters of his stamp, not only opposed the doctrines of the medical schools as then taught, but set forth a medical philosophy of his own, which was wholly speculative. It was a sort of medical atomic hypothesis, founded on the philosophical systems of Democritus and Epicurus, then popular with the educated Romans. It is from him that the popular medical theories as to the "pores" of the body have descended. He designated the Hippocratic method of patient observation of nature as θανατου μελέτη, "a meditation on death." His medical theories led to a simple enough practice. He had his plans for closing, opening

Archagathus.

Asclepiades. 90 B.C.

and relaxing "the pores," so that the imprisoned molecules could escape freely or not. Fevers, inflammations, and other "sthenic" diseases were due to obstructions of the pores; dropsy and similar asthenic diseases were due to relaxation. He had a sort of homœopathic maxim that one fever would cure another. Wine he administered according to the same theories which were adopted by Brown of modern times; a man whose history closely resembled that of Asclepiades in several particulars. Asclepiades was also hydropathic; for he made large use of cold water, and was the inventor of the shower-bath—the *Balneum pensile.*

Themison, pupil of Asclepiades. 60 B.C.

Themison, his pupil and successor, came from Laodicea, where already there was an important medical school,—an offset of the Alexandrian. He favoured the sect of the Methodists—a term which, derived from this body, received a singular application to a religious sect in the United Kingdom, founded in the year 1739 by John Wesley, a great ecclesiastical reformer, and a fellow of Lincoln College, Oxford. John Wesley and his friends at Oxford divided the day and the week into periods, during which they occupied themselves exclusively with certain pursuits, literary, charitable, and religious. It was from the practice of this orderly routine of duties that they were termed Methodists by their fellow-students at Oxford, for that ancient medical sect adopted a similar routine of treatment of disease. It was comprised within what was termed a metasyncritic circle; during this period each day had its allotted diet, regimen, duties, the treatment in minute details being distributed over successive days in periods of three days, or ternaries. Juvenal, in one line of his first satire, has intimated what success Themison had. '*Quot Themison ægros autumno occiderat uno.*' Methodism was a simple system; was therefore easily acquired; and, like all such, soon became very popular, especially amongst the unlearned.

Thessalus. A.D. 55.

Thessalus, a native of Tralles in Asia Minor, succeeded Themison, and fitly flourished during the reign of Nero. He was a man of low origin, and of ignorance and audacity unparalleled in that age of charlatans. Pliny describes him as professing to make his pupils perfect in medicine in six months. By this means he attracted a multitude of students, chiefly from the lower classes, whom he took with him on his visits to his patients for half a year, and conferred upon them an authority to practise medicine.

Soranus.

Soranus, a native of Ephesus, but a student of Alexandria, seems to have settled in Rome with the object of succeeding to the practice of the Methodists. He was, however, a man of scientific culture. He studied anatomy, published a work on the reproductive organs of the female, wrote an interesting life of Hippocrates, and systematized the practice of medicine. His contemporary and co-sectarian, Cælius Aurelianus, a Numidian, wrote one of the best works of the day on the practice of medicine, embodying not only the doctrine of Soranus, but all the most approved doctrines of the time. With a return to scientific culture in the leaders, the sect of the Methodists disappeared.

Celsus.

Cornelius Aurelius Celsus appears to have been contemporary with Asclepiades and Themison, or else to have lived shortly after them. He wrote on military affairs, agriculture, and rhetoric, as well as on medicine; and was probably a practising physician at Rome. He may be taken as the type of the learned or scientific Roman, and was evidently an eclectic. His work on medicine takes almost equal rank, as a classical work, with the Hippocratic writings; or he may, perhaps, be more fitly compared to Aretæus of Cappadocia, the most elegant and finished of the Greek authors of that day; and also, like Celsus, an eclectic. Celsus recommends, for the cure of hydrophobia, that the patient should be plunged over head into water, kept there for a short time, and then raised for a brief period and dipped again, repeating, alternately, the submersion and withdrawal. This practice has been preserved in the United Kingdom as a popular remedy (*Vide* article JENNER, vol. xii., p. 720), and is a curious piece of folklore, evidently derived, like many similar theories and practices, from the literature of medicine.

Period of culmination of Medicine in the Roman Empire.

Galen. Culmination of Roman medicine. A.D. 165.

The eclectic sect of Rome had in Galen its most distinguished member. He was, in all respects, a representative man. At this period science had recovered from the depression which followed upon the subjugation of Asia Minor, Greece, and Egypt by the Romans; and during the subsequent two centuries had even made considerable advance. Pliny had laid the foundation of natural history; Dioscorides of materia medica and botany. All the Greek schools supplied an uninterrupted immigration of scientific men into Rome and into the large commercial cities of the empire. It was about A.D. 165, and in the thirty-fourth year of his age, that Galen went to Rome on the invitation of the Emperor Marcus Aurelius. He was born at Pergamus, and was the son of Nicon, a geometrician, who took the greatest pains with his education. He was carefully grounded at Pergamus in anatomy, and was instructed in pathology and therapeutics by two masters; the one Stratonicus, being of the Hippocratic school; the other, Æschrion, of the Empirical. After the death of his father he went to finish his medical education at the great school of Alexandria. Having mastered all the theories and knowledge of the times, he gave his talents, and much time and labour, to constructing a summary of them. His works are therefore very voluminous, and constitute a perfect encyclopædia of the medical science of the day. It is for this reason that they took rank with those of Hippocrates, and that they constituted, equally with the latter, the text-book and manual of medical literature, down to the revival of learning in the fifteenth century. The term Galenist is hardly yet extinct in some parts of Europe.

The era of Galen was the culminating point of Roman science and literature. Marcus Aurelius, his patron, knew well how to value scientific culture. He was a man descended from a long line of noble Roman ancestors, and traced his pedigree, by his father's side, to Numa the philosophic king. He had every advantage of parental example and education, and was of the sect of the Stoics. The most distinguished member of that sect was Epictetus —already a Christian in his life and moral philosophy. This man Aurelius took for his model When he travelled into Greece he patronized science and philosophy of every kind; and on one occasion, when at Athens, founded four professorships for Platonics, Stoics, Peripatetics, and Epicureans, together with one for Rhetoric. He forbade persecution for religious opinions, and granted toleration to the Christians. Never was there a fairer prospect for science, and especially for medicine, than during the era of Galen.

The Military Power Supreme, and Decay of Medicine in the West.

Its decline. A.D. 165 to 466.

Yet the works of Galen constituted the last production of ancient Roman medicine. Everywhere the empire was being spoiled by barbarian foes, and the civilization of Rome was about to experience that long eclipse which continued through the dark ages. Aurelius passed, in defence of the empire, from the Rhine to the Danube, from the Danube to the Euphrates. Insurrections occurred in all parts; the unity of the empire was at last only maintained by military force, and the military force reigned supreme, electing and deposing emperors at pleasure. The effects of this grand change were soon manifest. The military power hated science. Hardly had Galen died, when Caracalla, the parricide and fratricide, visiting Alexandria under the pretence of worshipping the god Serapis, gave up the city to indiscriminate plunder and massacre, deprived the professors, who were Aristotelians, of their chairs, and suppressed all public discussions. He avowed a hatred of Aristotle; forbade the teaching of his doctrines; burnt his works; and persecuted to death his disciples. Caracalla was a representative man. He typified the age—an age when emperors had divine honours,—the military hierarchy was predominant, and religion and literature were equally debased. From this period the decline of medical science in Western Europe was rapid and continuous, until the incessant irruptions of the uncivilized nations of the north, and the interminable wars which resulted, reduced society to its elements. Boethius, born about A.D. 470, was the last of the Roman era of science; he was the martyr of philosophy. Thenceforward there was no longer anything but a shadow of philosophy or medicine, and all that remained was gathered under the wing of the new sacerdotal power that had arisen on the old; and which alone was able to overawe the brute force of the barbarians, and maintain social order. The era of Gregory the Great witnessed their revival.

Boethius, the martyr of philosophy.

SECTION V.—MEDICINE IN THE GREEK EMPIRE.

Partial revival of Greek Medicine in the East.

artial re-
ival of
reek me-
icine.
.D. 328.

Although medicine was all but extinct in the West, it survived in the East, which withstood longer the elements of social decay, and found a new starting point in the new metropolis of the empire, founded A.D. 328 by Constantine the Great. Greek medicine had never been defunct; it was only eclipsed by the cosmopolitan grandeur. All the cities of Greece proper, and the Greek colonies of Asia Minor, as well as Alexandria, cultivated every branch of science during the Roman dominion. Yet, when the centre of medicine thus returned to its cradle amongst the Greeks, a great change had come over its social relations. It was no longer in subjection to the Pagan mythology of ancient Greece. That was about to become extinct in a faith and a religion destined to be paramount, as it had been, over the civilized world. The change had proved fatal to society in the West; in the East the empire went through the process with less disaster. But the Greek empire, with all its schools, did little to advance medical science. The Christians objected to human dissection even more strongly than the Romans. Tertullian, partly a contemporary of Galen, but several years younger, vilified the memory of Herophilus, 500 years after his death, by designating him as "that physician, or rather butcher, who dissected 600 men in order to learn the structure of his frame; who hated man, in order to find out nature;" untruly adding that his victims "did not die a natural death, but expired amidst all the agonies to which the curiosity of the anatomist was pleased to subject them." Hence, when the Christians came to power, anatomical research was less than ever possible. The succeeding authors were, for the most part, mere copyists and commentators on Hippocrates and Galen. In the middle of the fourth century Oribasius flourished, who was one of this class. He also, like Galen, was born at Pergamus, was educated at Sardis, at the school of Zeno (who afterwards settled at Alexandria), and became attached to the court of Julian the Apostate, who repeatedly appointed him the Quæstor of Constantinople. He wrote seventy-two books, which, at the request of Julian, he abridged into one. He collates from several authors not noticed by Galen, so that his works constitute a valuable appendix to those of the latter. It is interesting to notice that, towards the close of the fourth century, a Phœnician bishop (Nemesius of Emessa) appears as a physiological writer. He closely verged, it is thought, upon the discovery of the circulation of the blood, but this is not well established.

basius.
. 360.

ius.
525.

Aëtius, the Christian, born at Amida, a city of Mesopotamia, on the Tigris, and who wrote about the beginning or middle of the sixth century, was a student of Alexandria. He summarized like Oribasius, and quoted also like him from authors not mentioned by preceding writers, and whose works are lost. He made a large collection of formulæ, including those of many secret remedies. His writings are more interpenetrated with Egyptian and Persian knowledge than those of Oribasius; and it was probably in consequence of his oriental birth and associations that he introduced into medicine the doctrine and use of spells, rites, and incantations, and which even then had begun to disfigure and corrupt Christianity. Alexander, the son of a physician of Tralles, a city of Lydia, was a contemporary of Aëtius, and also a Christian medical writer. He was a more original author than the latter, but, like him, was a believer in magic, charms, and incantations. He furnishes the only known instance of a medical writer who avowedly borrowed anything from Osthanes, one of the most ancient of the Persian magi.

Alexander of Tralles.

Procopius. A.D. 540.

Procopius, the historian, appears to have been a man learned in medicine, if not actually a physician. He mentions the names of several of his medical contemporaries, and records their services. He describes the plague of 543, which spread from Egypt over the known world, and carried off, at Constantinople, 10,000 persons daily when at its height. He uses terms of a scientific and technical character.

Culmination and Decline of Eastern Greek Medicine.

Culmination of Greek Medicine. Paulus Ægineta. A.D. 600–640.

Paul of Egina was the last of the more distinguished medical writers who lived during the palmy days of the Eastern or Byzantine empire. His birth is fixed sometime in the seventh century. He was a representative man, being a learned and practical physician, a voluminous commentator, and a skilful surgeon. He was a great compiler, adding from authors not quoted by his predecessors, as well as the original matter their own works contained. His works brought up the science of medicine to its latest development in the East, as Galen's had done in the West. Already while he wrote, the tempest which was to fall upon the empire with destructive force was gathering. Heraclius had to defend his empire on all sides; from the Longobards in Italy; from the *Arari*, who crossed the Danube, invaded Thrace, and marched upon Constantinople; and from the Persians, who advanced through Egypt and Syria, on the one hand, and Asia Minor on the other, as far as Chalcedon. In 622 he commenced his successful expedition against the latter, and in the same year Mohammed openly assumed the character of a legislator and a prophet. In 640 the Arabs under Amrou captured Alexandria. The schools of science and philosophy were broken up, the professors driven away, and the great library, as is stated by some, was burnt by order of Omar II. While the followers of Mohammed were wresting its fairest provinces from the Christian empire of the East, the Emperor Heraclius was engaged in a theological dispute with Pope John IV., who procured his doctrines to be formally condemned by a council.

Its decline.

The Greek empire was able to maintain itself at Constantinople against the Arabs; but it was mutilated, and became more and more degenerate, so that at the time when medicine was flourishing with the caliphs, in connection with political energy and vigour, it languished with the emperors, in association with religious and political decadence. Only one Greek name is prominently connected with the history of medicine from the century subsequent to the fall of Alexandria to the date of the capture of Constantinople. John, the son of Zacharia, lived at the close of the thirteenth or beginning of the fourteenth century, and was surnamed "Actuarius," an honorary title for the chief physician of the court. The religious bigotry and persecution which prevailed among the Greek Christians had at an earlier period the effect of exiling the best minds of the nation, and driving them for refuge to the colleges and

Actuarius. A.D. 1000.

universities of the politic caliphs. At a later period the ravages of the Turks drove them alike from the Moslem and Greek academies. Already, therefore, there were numerous literary Greek exiles in Italy and France, where they were cordially welcomed, when in the year 1453 the Turks having captured and pillaged Constantinople, a number of learned Greeks fled into Italy, taking with them all the literary treasures they could carry off. That event closed the era of the old Greek civilization and science, and at the same moment was the birth of modern and true European civilization, yet after a long period of gestation.

Extinction.
A.D. 1453.

SECTION VI.—MEDICINE UNDER THE ARABS.

Revival of Asiatic Medicine.

Arab medicine in Asia.
A.D. 622 to 1036.

The exodus from Alexandria carried the light of medical science back again into Greece, and Magna Græcia or Southern Italy. In the former its decline was delayed; in the latter, the school of Salerno was either founded, or materially strengthened, by the Alexandrian refugees, and the foundation laid for the revival of letters in Europe, under Charlemagne. Later on, when the Turks took Constantinople, and the last remains of Greek science were finally stamped out, Italy was in like manner benefited by the irruption of barbarians, and became the source of light to Europe. But the central seat of medical culture was now transferred to Asia, and once again medicine was developed by an Asiatic priesthood. No sooner had the conquering caliphs consolidated their government, than they encouraged the arts and literature with the same enlightened zeal and success as the Ptolemies. Science was again cultivated over a wide extent of territory, extending from the Indus to the Tagus. It is more than probable, indeed, that medicine and philosophy were taught in very remote regions of Asia; and even flourishing medical schools existed in India and Tartary. Of these, however, little is known, although it is expected that the extension of archæological research to Bokhara will throw much light upon the former state of civilization in these distant regions. Be this as it may, the sacerdotal power was once more triumphant in Asia, but with a new faith; and while every branch of science had its patronage, medicine in particular met with every encouragement. The Arabs generally had not only a strong liking for medical studies, but there is reason to think that the prophet himself was a student of medicine and a medical author. The schools at Alexandria appear to have been also re-established, for mention is made of professors there so late as the close of the seventh century; and at the commencement of the ninth, the patriarch of Alexandria was so celebrated for his medical skill, that the Caliph Haroun-al-Raschid sent for him to visit one of his sick wives.

The Pandects.
A.D. 687.

Syriac translations of the Greek medical writers were made a few years previously to the capture of Alexandria, which were termed Pandects. Through these the Arabians acquired a knowledge of European science. In 687 they were translated into Arabic. In 767 Bagdad was founded by the Caliph Almanzor the Victorious, a great patron of science. He was attended in a severe illness by George Bactishua, an Indian physician, who had been educated at Nisabur, the capital of Khorassan, long the seat of an important medical school. Bactishua was most graciously received by the caliph, and at his departure was presented with the imperial fee of 10.000 gold pieces. At the caliph's request he translated numerous medical works into Arabic. The great translator, however, was Honain, a Christian well acquainted with Greek, Syriac, and Arabic, and possessor of a library rich in works on every branch of science. It is stated that the Caliph Almamon paid him in gold, for translating Aristotle, a sum equal in weight to each volume of his translation. He was known as Honain the Translator. His example was followed by his son Isaac, and his grandson Hobaish, both of whom enriched Arabic literature by translations of the best European writers.

Era of Haroun-al-Raschid.
A.D. 784.

The fifth caliph of the House of Abbas, Haroun-al-Raschid, was remarkable for his love of science. He welcomed scientific Christians to his court, adorned Bagdad with colleges and hospitals (which were added to under Almamon), until it rivalled Alexandria and Athens as a seat of scientific culture, and contained not fewer than 6000 learned Christian exiles within its walls. He it was who first set the example of attaching to every mosque that was built a college and an hospital,—an example which was most strictly followed by the Spanish Moors. The most distinguished medical professor at Bagdad at this period was Mesue, the son of a druggist, born at Nisabur. The pupil of Gabriel, the son of George Bactishua, he was especially commissioned by Haroun-al-Raschid to collect and translate into Arabic all the Greek works to be met with in Ancyra or other towns in that part of Asia.

Almamon, the second son of the great caliph, ascended the throne in 840, and devoted himself with the utmost enthusiasm to the advancement of science. He collected the works of the learned from every quarter, applying, on the one hand, to the Greek emperors at Constantinople for assistance in his pursuits, and rendering the Sanscrit literature available on the other. He erected observatories, and had astronomical instruments constructed for the purpose of facilitating astronomical observation. He derived much knowledge of astronomy from Hindustan.

Rhazes.
A.D. 882.

Rhazes was born in the year 852 at Rei, a city of Persia, and educated at Nisabur. At the age of thirty he removed to Bagdad, where he subsequently attained to a high reputation. He was a voluminous writer, but the greater number of his works were compilations from the Greeks. He wrote original works; amongst these is a treatise on small-pox and measles, which was translated into Greek at the desire of one of the Byzantine emperors.

Culmination of Arab medicine in Asia.
A.D. 1036.

The beginning of the eleventh century witnessed the highest development of Arab culture in Asia.

Avicenna.
A.D. 980.

Haly Abbas and Ebn Sina, or Avicenna, were nearly contemporaries, and both copious Arabian writers. The former has left a full account of the state of medicine amongst the Arabs, and a history of their medical writers. About the year 980 he wrote a voluminous work, intended to be a complete system of medicine, which he called *Almalecus*. But Avicenna was the Galen of the eastern Arabian empire. His great work was entitled the *Canon*, and became the text-book of Arabian commentators and teachers during the twelfth and thirteenth centuries. It had also an extended reputation in Europe even at an earlier period, which it maintained until the revival of letters. Avicenna died in 1036. Besides medicine, he cultivated philosophy, mathematics, and politics, and was at one time vizier to the sovereign of Hamadan. Only one other name appears in the history of the caliphs of Bagdad in connection with medicine,—that is Abdallatif, contemporary with Saladin. While that prince was at Jerusalem after the peace was concluded with the Christians, he gave lectures in the temple.

Decline of Arab medicine in Asia.
A.D. 1242.

At the time of Avicenna the caliphate of Bagdad had already gone through the same changes as the Roman empire at the time of Galen. The body-guards of the Caliph, the head of the faithful, possessed the same power as the prætorian guards of Rome. The distant regions of the empire were being attacked by the Turks, and various provinces formed into independent kingdoms under military commanders. Henceforth medicine made no progress amongst the Arabs. The physicians were little better than commentators and theorists. It was the period of political and religious decay. The Turks finally conquered Bagdad, and swept away all traces of science.

Rise of Arab Medicine in the West.

Rise of Arab medicine in the West. A.D. 748.

Medicine, in common with other sciences, found amongst the Mohammedans of the West the same support and encouragement as amongst those of the East. In the year 711, the Arabs penetrated into Spain from Africa, and laid the foundation of the Moslem empire in Western Europe. For nearly fifty years it was a distant dependency of the eastern seat of Arab power, and exposed to civil wars; but when the Ommiades or Beni Umeyah dynasty was overthrown by the Abassides in 748, a descendant of it, Abd-el-Rahman escaped from Bagdad and took refuge in Spain, where, after a series of conflicts, he established himself in the government, making Cordova his capital. His successor, the third of his name, who reigned in the tenth century, was the greatest monarch the Spanish Moors ever had. He followed in every respect the example of Almanzor and Almamon at Bagdad. He fostered every kind of science and art, founding colleges, schools, libraries, and constructing roads, canals, and aqueducts. The impulse then given was continued during the reign of his son and successor Al Hakem II., who, himself a scientific man, had an unbounded love for science and literature. He attracted the learned men of every country to his court, and founded the library of Merwan, of 250,000 works, at Cordova, the unfinished catalogue of which filled forty-four folio volumes. Within five hundred years from the conquest of Spain by the Arabs, science had been so developed that it could boast of seventy public libraries, three academies at Seville, Toledo, and Marcia, besides the world-famous university of Cordova, and hundreds of authors and teachers.

Culmination and Decline of Arab Medicine in the West.

Its culmination. A.D. 1150. Avenzoar.

Avenzoar was the Galen and Avicenna of Spain. He was rich, of noble birth, but a Jew both by religion and race. His father and grandfather were equally men of high reputation in the medical profession, as indeed was his son. A learned commentator, he was also an original observer, so that his works were hardly less valued in the scientific world than those of Ebn Sina. He flourished at the beginning of the twelfth century. Averrhoes was junior to Avenzoar, but also a contemporary, being his reputed pupil. He was educated in the university of Morocco, where he first studied law, but which he abandoned for medicine, mathematics, and philosophy. His father was the high-priest and chief judge of Cordova, and to these offices he succeeded on the death of his father. He was, however, subsequently deprived of them, and thrown into prison for his avowed scepticism. He illustrated the Aristotelian philosophy, from which circumstance he acquired the surname of "The Commentator;" and he wrote a system of medicine expressly intended to be a compilation. Averrhoes died about 1206.

Its decline. Albucasis. A.D. 1300.

Science was thus at its culminating point in antagonism with traditional theology. Concurrently the Moorish empire was declining, and at last was rent by bloody civil wars. The great battle of Las Navas, fought in 1213, struck at the root of the Moorish power. In 1226 Cordova, with its famous university, was surrendered to the Christians, and the Moorish King of Granada purchased peace by becoming the vassal of Ferdinand III. Spanish literature, arts, and science, declined with the declining power of the Moslem, so that Albucasis, the last of the Moorish practitioners of Spain, and who lived about the beginning of the fourteenth century, writes of surgery as being at the lowest ebb.

Its extinction. A.D. 1453.

Spain still retained, however, her universities and much of her learning after the expulsion of the Moors. In 1512 George Almenar published on syphilis; but the succeeding Christian governments fell under an exclusively sacerdotal and fanatical influence. The Jews and Moslems had been, and were, the chief supporters of science; but that scientific toleration which the latter had accorded to all creeds was not accorded to them. Jews and Moors were diligently extirpated by the Inquisition; their literature was pronounced devilish,—themselves accursed. This priestly blight of science fell upon Spain at the identical epoch when the rest of Europe was beginning to cultivate every branch of human learning, and is felt in that country to this day. So ended Saracenic medicine.

CHAPTER II.—MODERN OR EUROPEAN MEDICINE.

SECTION I.—FIRST PERIOD: FROM THE DARK AGES TO THE REFORMATION.

Sacerdotal Stage of Modern Medicine.

First period of modern or European medicine. A.D. 466 to 1453. Sacerdotal stage.

The imperial dominion of Rome virtually ended with the capture and sack of the city by Ricimer in 472, and actually with the abdication of Augustulus in 476. This finished the succession of phases of ancient European society. Commencing with the sacerdotal power of the old priesthood, it had ceased with the fall of the military hierarchy, and once again the whole series began anew with a new faith and new races of men. Amidst the troubles of the dying empire, the municipalities had held to laws and government, and the people had found the best guarantee for peace and order in the superior wisdom and influence of the clergy. It was, however, in 466 that the sacerdotal period of modern European civilization formally commenced, in which year the Bishop of Rome (henceforth to be so powerful) was elected to fill the episcopal chair by the united voice of the clergy and people. From this date, the sacerdotal caste was gradually but surely to rise above the military, and become predominant; not by means of a conquering prophet or a military caliph, but by a reconstruction of the framework of society on the first principles of human nature. The period between the close of the fifth and the middle of the seventh century was occupied in a slow but gradual civilization by religion of the barbarous populations of both the West and the East. As a consequence, we see a gleam of light bursting forth at last in the eighth and ninth centuries over the whole earth, from Ireland in the west to the farthest east of Bokhara and Hindustan. It was a period of a grand onward movement of the human mind from that state of degradation to which the old pagan idolatry (commencing first with symbolism) had reduced it. We have already seen what the monotheistic priesthood and warriors effected in Asia.

Charlemagne. A.D. 771.

Charlemagne in the eighth century rivalled his contemporaries, the caliphs of Bagdad, in his encouragement of the arts and sciences. In his reign the cathedrals and monasteries of Christendom, like the mosques of the Moslem, had libraries, schools, and colleges attached to them, in which medicine was taught in especial under the name of physics, or the philosophy of nature. Priests, abbots, and bishops were students of medicine and the physicians of kings. Nay, even abbesses and nuns studied and practised the art. While the Arabs were encouraging the sciences and arts in Asia, Africa, and Spain, Alfred of England was endeavouring to develope them in Britain. The epoch was in fact one of general revival of science and civilization; but its onward movement was interrupted by the continual attacks of the pagan barbarians of the North on the one side, and the Moslem on the other. The former at last got possession of the fairest provinces of Northern Europe, and with them ignorance and a retrograde social condition of that country came on. In the regions of Europe most distant from their attacks, as Italy, the south of France, and Spain, medical and general science continued to advance up to the close of the thirteenth century. Salerno, in the south of Italy (the old Magna Græcia), which

Alfred of England.

Constantine of Carthage. A.D. 1075.

was already in high repute as a medical school so early as the eighth century, maintained an eminent position from the tenth to the thirteenth. Constantine of Carthage, one of the professors during the latter half of the eleventh century, travelled, like a second Pythagoras, in search of knowledge through Egypt, Ethiopia, Arabia, Persia, and India,—countries in which the natural sciences and the arts were at their zenith under the caliphs, and would doubtless return, like his great predecessor, well stored with the philosophy and medical science of the East. Probably the development and vigour of this school was due to its proximity to the East. Portions of Naples also maintained close ecclesiastical relations with the Byzantine empire for several centuries, and the old Greek culture flourished there for a longer period than elsewhere in Europe.

Rise of a Medical Profession in Europe.

Medical profession in Europe. A.D. 1100 to 1453.

During this period the people inhabiting the shores of the Mediterranean went through the successive phases we have repeatedly traced already. Commerce introduced wealth,—wealth was followed by science and arts; then freedom of opinion was demanded, and the power and dogmas of the priesthood questioned: this in return appealed to the military power. Next arose the old conflict between traditional dogmas and new opinions, with a loosening of the ties of society, to end in the loss of political and religious freedom.

Era of the Troubadours, 12th century; and foundation of universities.

Thus in these regions the twelfth, thirteenth, and fourteenth centuries were remarkable for great commercial, religious, and intellectual activity, and an attempt at a reformation of religion, upon this followed the establishment of the Inquisition and the wars against the Albigenses. The sacerdotal power triumphed and became absolute; and the next phase came. It was now that the practice of medicine was separated from the priestly caste, and declared to be incompatible with the sacerdotal office. For several years decrees of councils and bulls of popes were launched against the combination of the two by the priesthood. Science and philosophy were thus secularized, for the study of medicine was then (as since) the study of all branches of human knowledge; hence another important social change arose. The cathedral schools were very generally erected into universities by the popes of the twelfth, thirteenth, and fourteenth centuries; science and literature thereby received the highest patronage, a home, and a special organization, and with these advantages they were rapidly developed. Encouraged by popes and prelates, the acquisition of literature from all available sources became an enthusiastic pursuit. The schools of the Moslem and Greek were visited, and their great medical and scientific authorities commented on and used as text-books. In short, it was an anticipation of the age of Leo X.

Albertus Magnus. A.D. 1256.

Of the mixed scientific and medical authors of this era, Albertus Magnus and Roger Bacon are the two most distinguished; the one a prelate in high favour with the papacy, the other a Franciscan priest alternately encouraged and persecuted. Both took a grand and comprehensive view of natural science in its practical relations, and included therein medicine and its accessory departments.

Mondini. A.D. 1316.

Practical anatomy was restored by Mondini, professor of medicine at Bologna, in 1316. He dissected the bodies of two women, and published a work on anatomy with plates. Surgery and medicine were advanced by Arnold de Villeneuve and Guy de Chauliac. The former travelled into Moslem Spain at the close of the thirteenth century, to be instructed in Arabian pathology, materia medica, and chemistry. It was here that he probably acquired a knowledge of alcohol, of which it has been alleged he was the discoverer. The name is manifestly of Moorish origin.

Guy de Chauliac. A.D. 1350.

Guy de Chauliac was a representative man, and deserves special notice. He flourished in the middle of the fourteenth century, and was one of the learned surgeons of this epoch. He had mastered Arabic and Greek literature, and his writings constituted a summary of all the then existing knowledge, and took rank with the established authorities of medical science and art. They were adopted as text-books for both professors and practitioners, and were translated and commented upon by the learned of all nations.

Extinction of Troubadour learning.

During this entire period the sacerdotal power was irresistible. At the beginning of the thirteenth century an attempt was made to assert and maintain religious liberty in both the south of France and in Italy, and the former at last became the seat of bloody religious wars, in which the dawning Reformation was finally quenched in blood. In Italy the Inquisition was put into full operation, and the heretics were unsparingly persecuted during the whole of the thirteenth and the beginning of the fourteenth centuries. Medicine and the natural sciences did not escape. Roger Bacon suffered the same fate as Galileo in the succeeding epoch, two centuries later; and the Inquisition tried Peter de Apono, a physician and naturalist, for heresy, after his death, and ordered his body to be disinterred and burned. In this age, therefore, there arose a bloody struggle between religious truth and corrupt traditions, and between natural and experimental science and the dogmatic theology based on the philosophical speculations of Aristotle. The latter was victorious. The sacerdotal power exercised a triumphant tyranny over the people, and so became more and more wealthy and corrupt. From this date a sensible decline may be observed in medical science and art for a century.

SECTION II.—SECOND PERIOD OF MODERN MEDICINE: FROM THE COMMENCEMENT OF THE GREAT REFORMATION TO THE FALL OF THE SACERDOTAL POWER.

Phase of Development under the Priesthood.

Second period of modern European medicine. A.D. 1450.

At the commencement of the fifteenth century commerce had acquired an extraordinary development in Italy and along the shores of the Mediterranean, and therewith the arts and sciences,—for they always follow in its train. Before its close, editions of the Greek and Latin classics, hitherto only to be met with in manuscript, were printed. Andreas Verrochio, the director of the Academy of Arts at Milan, and the master of Leonardo da Vinci, impressed upon artists the necessity to excellence in art of anatomical knowledge. Da Vinci (born in 1452) carried out these ideas into practice, and carefully dissected the human body at Vaverola. He made very many beautiful anatomical drawings, which still exist. Da Vinci was also an observant physiologist, a profound mathematician, a skilful architect and engineer, as well as a painter and sculptor.

The period was in truth one of immense progress in every direction. Society was more and more consolidated, commerce extended, political freedom developed. It was, like the period of the Greek republics, an age of large cities and small independent communities, the rulers of which encouraged science and art and learning by all the means in their power.

The Medici. A.D. 1389-1521.

The first manifest movement arose with the wealthy merchants and republican governments of the large commercial cities of Italy. As they declined from intestine wars and feuds, the military power usurped authority, and the republics fell under the power of successful military commanders; yet, nevertheless, these also continued the public patronage of science and art already begun. The history of the Medici family of Florence, in its relations to philosophy, science, literature, and the arts, from Cosmo the *Pater Patriæ*, born in 1389, to Leo X., who died in 1521, is in fact a history of what this class did for science in all parts of Italy. Giovanni de' Medici died, in 1428, a wealthy and successful merchant, leaving two sons, both of whom, as well as their descendants, occupy an important position in the story of Italian progress. Cosmo the Elder continued the extensive commercial enterprises of his house, and at the same time surpassed almost all the princes of Europe in his munificent support of literature and science. He founded a philosophical academy at Florence; collected, by means of his numerous commercial agents, the Greek, Latin, and Arabic MSS. which formed the basis of the Laurentian Library; and administered a liberal hospitality to learned men. He died in 1464. His grandson, Lorenzo the Magnificent, carried on the scientific and literary enterprises which Cosmo had begun. He also encouraged the cultivation of the Platonic philosophy; collected MSS. from every quarter, but especially from the East; and when the art of printing was discovered, instigated the publication of collated and correct editions of the classical writers. On the capture of Constantinople by the Turks, he welcomed and employed the learned Greek refugees as professors and teachers of the Greek language, literature, and philosophy.

Age of Leo X. A.D. 1513.

Leo X., a great sacerdotal ruler,—the Haroun-al-Raschid of his era,—was the son of Lorenzo the Magnificent, and trod in the steps of his ancestors in their patronage of literature. He founded a Greek college at Rome; established a Greek press under the management of John Lascaris, who had brought 200 MSS. from the East for his father; restored the university of Rome in all its departments; collected all available talent about him, whether of science or art; and took every possible means to add to the literature of the times. This was "the age of Leo X." It was the culminating point of European mediæval civilization and science, and the hour of final departure of the old Greek. Its great characteristics are two,—the restoration of Greek philosophy and literature to Europe, and the discovery of the art of printing. Henceforth science was to march forward independently of kings and priests; with a printing-press it passed over to the people, and there won a dominion of its own.

Linacre in Italy. A.D. 1484.

Fernel.

The immediate effect on medicine of the capture of Constantinople was to give a new impulse to the cultivation of Greek medical science and literature. The learned fugitives who became teachers of both the Greek medicine and philosophy in the Italian universities and academies, attracted to their lectures enthusiastic students from all parts of Europe. In 1484 Thomas Linacre, the founder of the College of Physicians of London, left Oxford for Florence that he might attend the lectures of Demetrius Chalcondylas, an Athenian refugee, and became at the same time an inmate of the palace of Lorenzo de' Medici, as companion to that prince's children. From Italy the taste for books, libraries, and sound learning was diffused over Europe. A great number of ancient works were edited, translated, and commented upon. The authenticity of MSS. and the purity of texts were closely scrutinized; and finally the great mass of Greek and Arabian medical literature was irrevocably made European. In little more than a century from that date, Anuce Foes had completed his great undertaking,—the first and best Latin translation of the Hippocratic writings. Concurrently with this important movement, original authors arose in great numbers, who contributed to its progress, or summarized the results. Of the latter class was John Fernel, born in 1497 at Clermont, and physician to Henry II. of France. He was both a Greek and Arabic scholar, a profound mathematician, and an original thinker. He boldly questioned the dogmas of Galen, then almost considered sacred, and gave a new impulse to systematic medicine. He was, in fact, the Ebn Sina and Galen of his epoch.

Phase of Conflict with Sacerdotal Power, and Decline of the Latter.

Phase of conflict of modern medicine.

Decline of sacerdotal empire. A.D. 1517.

It may facilitate the comprehension of the true position and character of existing modern medicine to look back upon the long and devious course we have travelled, extending, indeed, over 3000 years. Our first glimpses of medicine show it in intimate connection with sacerdotal predominance in India, Egypt, Judea, Phœnicia, Greece, as far back as we can see in its history. Fifteen centuries of the Christian era have elapsed, and we find it in intimate connection with sacerdotal predominance still. The head of sacerdotal power of Christendom bears the title of Pontifex Maximus, like his Egyptian prototype and his Roman predecessor; and that power has been predominant for more than 1000 years. Already, in the fourth century, the bishops and clergy were the ruling municipal authorities; and when the Bishop of Rome assumed and asserted supreme power over all other authority in Christendom, he was but the proclaimer and impersonation of a long existing reality. But that power is at its culmination, for we find all those phenomena in the development of medicine which mark an epoch. Religion is, in fact, no longer the binding tie of society; the head of the church hardly thinks it necessary to be even of good moral conduct; the augurs laugh in each other's faces; and the financial, æsthetic, and scientific development of the church is at the highest. For all that, the decay of the sacerdotal empire of Rome has already commenced. The new reformation begun in Italy at this epoch by Savonarola and others was quickly quenched in blood, as in the thirteenth century; but the field of conflict was wider than in that period, and in a few years it burst forth in Germany. There Tetzel was as impious with his indulgences as Alexander when he assumed to be Jupiter, or as the Roman emperors when they proclaimed themselves to be divine. Savonarola was executed on May 23, 1498; Luther affixed his ninty-five propositions to the gate of the castle church of Wittemberg on 31st October 1517. From that day commenced the disruption and decline of the sacerdotal empire in Europe. Since then the seat of sacerdotal power has been transferred to the north-east, and the Emperor of Russia wields the dominant sacerdotal sceptre of the world. He it is who, from small beginnings at this era, has risen to be the usurping head of the Greek church, with his chair fixed temporarily at Moscow, but his hopes on Constantinople. All experience shows that the course of the sacerdotal czars will be necessarily militant and aggressive,—that is, conquering. The head of the Mohammedan priesthood is all but defunct; his extinction is but a question of time and accident: he is a political necessity only,—a Turkish high-priest supported by Christians.

It was not long before medicine experienced in Italy, in common with the sciences generally, the consequences of the change we have described. The impulse given to them during the era of the free commercial republics ended finally in depression under a leaden despotism. Throughout France and Germany the era of those religious wars succeeded which thinned the population, devastated towns, interrupted commerce, and by again rendering the sacerdotal power secure, although with diminished empire, laid the foundation for the great revolution which commenced at the close of the eighteenth century. Great Britain and the Baltic states being remote from the thick of the fight at the great Reformation, happily escaped in great measure: the north of Germany sank down exhausted.

The true basis of modern civilization.

The discovery of printing placed the means of acquiring knowledge in the hands of the people. Protestantism demanded and obtained for them the right to the free use of those means. The great political principle of Christianity, that all men have equal rights before God and the law, became an article of faith both political and religious. It is upon this principle that the true European civilization is based; all others are but a continuation of the old and really oriental civilization. Hence the Reformation was the great *punctum saliens* of a new form of social life destined to be ever in conflict with the old; and to the countries of the Reformation medical science at last fled. While, then, the centre of sacerdotal empire has passed from Rome to Moscow, the centre of commercial and scientific empire has passed over to London and the universities of Great Britain. Remarkable is it to see this empire already confronting the great sacerdotal ruler of the world in both Europe and Asia, and supporting politically the two decaying priestly rulers of Rome and Constantinople, as a counterpoise to the younger and more vigorous. Remarkable is it, too, to see that her language is spreading through every region; that her scientific arts are changing the face of civilization by giving an incalculable increase of social and material power to man; and also, which is more to our purpose, remarkable is it to see that she is restoring medicine and the arts to those countries from whence, in connection with the sacerdotal form of government, they seem to have originally sprung. British medicine has taken root in both India and China. In India, schools, colleges, libraries, are established and multiplying, and the educated natives acquire a knowledge of English science and literature as the ancient world of Europe sought a knowledge of Greek, and the mediæval of Latin. The history of medicine may with justice, therefore, be especially associated for the future with its progress in Great Britain.

SECTION III.—THIRD PERIOD OF MODERN MEDICINE: FROM THE REFORMATION TO THE CLOSE OF THE NINETEENTH CENTURY.

Origin and Development of a Medical Profession and Medical Literature in Great Britain.

British medicine. A.D. 1518 to 1800.

16th century. Linacre. London College of Physicians.

Linacre proceeded from Florence to Rome, and studied medicine and natural philosophy, applying himself more especially to the works of Galen and Aristotle. Having graduated at Padua, he returned to Oxford, where he gave temporary lectures on physic, and taught the Greek language. Henry VII. employed him professionally; and he stood high with his successor Henry VIII., who patronized men of letters. Cardinal Wolsey was like-minded, and, as the result of this patronage, it was stated that the English court contained more men of learning than any academy. Thus dawned the Elizabethan age in England. At this time the bishops in their several dioceses had the power of granting licenses to practise medicine. It was therefore followed as a profession chiefly by illiterate monks or by unlicensed empirics. To remedy this evil, Linacre exercised his influence with Wolsey, and procured letters patent, dated 1518, founding a college of physicians in London, and was elected the first president. He entered into holy orders before he died. (See LINACRE.)

Kay.

John Kay, born in 1510, succeeded Linacre. He founded the only medical college existing at Cambridge. Like Linacre, he was an erudite physician, and studied Greek and medicine in Italy as well as at home.

17th century. Harvey.

Harvey lived at a time when the novelty of Greek literature had passed away, and men's minds were turned to original research. Like Linacre, he graduated at Padua, where he studied anatomy under Fabricius ab Acquapendente. Returning to England, he made the famous discovery of the circulation of the blood. (See HARVEY.) Sir Thomas Brown, the author of *Religio Medici*, was his contemporary, but his junior.

Sydenham.

Sydenham was another of the first great English physicians who were born and educated before the civil wars. He has raised the name of English medicine as high as any. Montpellier was then a celebrated school of medicine (for the Italian schools were already declining), and to this Sydenham repaired after graduating at Oxford. Like Harvey, he took a side in the civil war, but as a parliamentarian, and was more of a partisan; Harvey being the physician to Charles I., remained simply faithful to his friend and king. Sydenham was, however, younger than Harvey by 46 years, the date of his birth being 1624, when the discovery of the circulation had been already before the scientific world for four years. These two men initiated great changes in medical science.

Riolan.

Anatomy. Malpighi.

Pecquet.

Physiology. Mayow.

Chemistry.

Paracelsus.

Several distinguished men arose on the Continent at this epoch, and influenced the progress of medicine. John Riolan of Paris was the principal opponent of Harvey, and being the greatest anatomist of his age, his opinions had much weight with his contemporaries, and delayed the recognition of Harvey's discovery by the medical world. When at last it was accepted, the changes in medical researches and theories were rapid. Malpighi, working in 1661 with the microscope, demonstrated the motion of the blood-corpuscles in the capillaries. The discovery of the anatomy of the lacteal vessels (1647) by Pecquet, a student at Montpellier, had already overthrown the current theories as to the relations of the liver to the circulation; and in 1661 Malpighi showed the true anatomy of the pulmonary tissue and its relation to the circulation. Hence arose new theories of nutrition, respiration, and circulation. In 1668 Mayow approached very near to the modern theory of respiration. While anatomy and physiology were advancing with such long strides, all the other branches of medical science were progressing too. The cultivation of the occult sciences had led the physicians and philosophers of the latter end of the fourteenth and the beginning of the fifteenth century to Arab literature; and knowledge acquired by the Moorish chemists, especially of Spain, was applied to medicine. Thus the foundation of modern chemistry was laid. Very soon the principles of the science were applied to anatomy, physiology, and pathology. In 1527 Paracelsus was professor at Basle, teaching a strange mixture of magic, astrology, geomancy, and medicine, and introducing powerful chemical remedies into practical medicine, especially mercury and antimony. He commenced his first course by publicly consigning to the flames the works of Galen and Ebn Sina. A century later Van Helmont partly founded the iatro-chemical school of which Sylvius, or Francis de la Bois, professor of medicine at Leyden in 1648, was the most distinguished ornament on the Continent, as was Willis in England.

Medical psychology. Willis. A.D. 1659.

Thomas Willis was one of the physicians of the time of the great civil war. He took the side of the king. At the Restoration he received the appointment of Sedleian professor of natural philosophy in the university of Oxford. In the preceding year (1659) he had already published chemical theories of fever and of the urine, in which he adopted the doctrines of Sylvius. Willis was, however, more remarkable for his researches into the anatomy, physiology, and pathology of the brain. He it was who first distinctly advanced and applied the modern doctrine, that the brain is a congeries of organs, and who especially assigned the cerebellum to the involuntary movements. Van Helmont in the preceding century had broken the ground of physiological metaphysics, and had theorized on the *Archæus*. Willis, following Van Helmont in this department as well as in that of iatro-chemistry, entered into those profound metaphysical discussions which then occupied the greatest thinkers of the day, such as De la Bois, Descartes, Newton, Leibnitz, Locke, Hobbes, Grew, Sydenham (in his *Theologia Rationalis*), Wedel (of Jena, then a renowned university); and, later on in the century, Hoffmann and Stahl. Willis was a man of great practical piety. He appropriated all his Sunday fees to charitable purposes; he procured a service to be performed early every morning in a church in St Martin's Lane, that he might be able to attend before he visited his patients; and he dedicated his treatise *De Animâ Brutorum* to the Archbishop of Canterbury. All this did not prevent the calling in question of his orthodoxy by the theologians; for the old sacerdotal spirit of unquestioned predominance and Aristotelian preference still remained in the reformed clergy.

Midwifery. Mauriceau. A.D. 1668.

Midwifery first took its origin in this century as a distinct department of medicine. The *sage-femme* of Marie de' Medicis published in 1609 or 1626 a collection of obstetrical observations; and in 1668 the appearance of a formal treatise by Francis Mauriceau, chief accoucheur to the Hôtel Dieu in Paris, laid a stable foundation for the science and art.

Surgery. Wiseman.

Surgery had not such a crowd of promoters as the other branches of medicine. Foremost amongst them was Richard Wiseman, surgeon to Charles I. and his son during the civil wars. He was taken prisoner at the battle of Worcester. At the Restoration he was appointed serjeant-surgeon to Charles II.

Botany. Gesner. Grew and Ray.

Botany had already been largely advanced in connection with materia medica in the sixteenth century. Its revival arose partly from the efforts of commentators, as Anguillara and Facho, to illustrate the older writers, partly in the occult doctrine of signatures adopted by mystics like Paracelsus, Baptista Porta, and Crollius. Conrad Gesner of Basle principally laid the foundations of modern botany in the middle of the sixteenth century. He was followed by Andrew Cæsalpin and others. In England Grew, in the year 1682, advanced vegetable anatomy and physiology far beyond his contemporaries; while John Ray laid the foundations of zoology as well as of English botany. Woodward, one of the founders of English geology, belongs more to the next century.

Animal mechanics. Borelli. Pitcairn.

Mathematics was much cultivated at this time, but more particularly in reference to dynamical philosophy. Two natural philosophers, Sir Isaac Newton and Leibnitz, were at the head of the mathematicians; but several physicians engaged in the study, and applied the science to medicine. These were the iatro-mathematicians. The discovery of the circulation and of animal mechanics in connection with anatomical research, naturally led to this method of investigation. Borelli of Pisa was the founder of the sect. The first volume of his great work *De Motu Animalium* was published at Rome in 1680, the year after his decease. Bellini, his pupil, followed up his views; and later on, Baglivi, the Roman Hippocrates, applied them to pathology. In Great Britain Archibald Pitcairn of Edinburgh, the pupil of Bellini, applied mathematics to medicine. It was, however, in the beginning of the following century that these iatro-mathematical theories received their full development.

This very general and rapid survey of the state of medicine in the seventeenth century will at least suffice to show that it advanced more in every department during that stirring period than in any preceding century, not excepting that in which the school of Alexandria was established. The age was one of progress throughout. The impulse given to learning during the close of the sixteenth century was felt in every department of human knowledge; nor did the civil wars in Great Britain and Ireland at all diminish its effects; perhaps they rather kept it up by developing men's energies.

Foundation of medical societies. Origin of the Royal Society. A.D. 1645.

The most striking event of this epoch in the history of medicine is the foundation of the Royal Society of London, the first of the kind constituted out of Italy. It is of sufficient importance to merit special notice. We have seen that in the eighth century the learned societies were sacerdotal in their origin, being connected either with mosques, monasteries, or collegiate churches; that in the thirteenth and fourteenth centuries they were less sacerdotal, and appeared as universities, yet under the protection and control of the church. In the sixteenth and seventeenth centuries medicine (still as physics) had so widely extended its limits, that it required special institutions for their development, for in truth they comprise within them every branch of natural philosophy. The universities were leavened with the old Aristotelian philosophy; medicine wanted the new. The theologians were still predominant in them, and fettered inquiry; medicine wanted freedom. Politics were discussed with sword and gun; medicine wanted to seek after truth in peace. Hence it happened, that in the very hottest of the great civil war some of the most distinguished of the English school of medicine banded themselves with other investigators of nature, and, with their co-operation, finally established the Royal Society of London, the modern head and home of natural science.

Attacked by the sacerdotal power.

It is worthy of notice that the supporters of the sacerdotal power instinctively perceived the new society to be an enemy; and in 1667, seven years after its formal foundation, Dr Sprat, afterwards Bishop of Rochester, had to defend it from their attacks. It was objected that the society neglected the wiser and more discerning ancient philosophers, and depended too much upon their own unassisted powers; that, by admitting men of all religions and all countries, they endangered the stability of the established church; and, more than all, that a philosophy founded on experiment was likely to lead to an overthrow of the Christian religion, and even to a formal denial of the existence of God. It was on such grounds that the old Greek philosophers were persecuted to death. The Roman priesthood of Christendom had met the scientific men and discoveries of the two previous centuries in the same spirit and with the same argument. Unhappily for themselves and for religion, they also possessed the power of compelling at least an apparent submission to them. Galileo Galilei demonstrated the falsehood of the Ptolemaic system; but the priesthood had affirmed its truth, and as their authority rested on the assumption that they were infallible, to question their dogmas was to shake the very foundation of their power. Galileo was therefore compelled to recant his opinion, that the earth moved round the sun; but his whispered reservation of "It moves for all that," was as prophetic of the advancement of philosophical truth as of the certain recognition of his own doctrines.

Medicine in the eighteenth century. Clinical medicine.

In Protestant countries natural science was now free. The beginning of the eighteenth century was especially characterized by the establishment of CLINICAL MEDICINE, or bedside teaching on a systematic plan. The obvious necessity to the student of a practical acquaintance with disease must have been felt at all periods of the history of medical art. The simplest method of securing this to him would be for his master to take him to the bedside of the sick. In private practice the facilities for this method are limited by the inconvenience which is necessarily inflicted if any number of students enter private houses. Hospitals, therefore, or at least public institutions of some kind for the reception of the sick, have been usually used for this purpose. In modern times the first recorded attempt at systematic hospital instruction was made at Padua in 1578, About the commencement of the seventeenth century, Otto de Heurn introduced it at the university of Leyden.

Boerhaave. A.D. 1701.

The celebrated Francis le Bois succeeded him in 1658, and attracted numerous students for a period of fourteen years. The fame of Leyden as a medical school seems to have begun at this time. The method does not appear to have been continued after his death, or went on at least with much less *éclat;* but in 1701 Boerhaave, a representative man, was elected to the chair of the institutes of medicine, or physiology. He was destined to impress his character upon European medicine for half a century.

Hermann Boerhaave, the son of a country Protestant clergyman, resident two miles from Leyden, was originally intended for the church. At the age of eleven he could read Greek and Latin with tolerable accuracy. To these languages he added the study of Hebrew and Chaldee, with ancient and modern ecclesiastical history and mathematics. When aged twenty-one (in 1689), he took his degree of Doctor of Philosophy, and selected as the subject of his inaugural thesis, "the distinction between the soul and the body." This indicated the bent of his mind. He was taught mathematics that he might be able to pursue his studies in medicine; and finally, at the age of twenty-five, took the degree of Doctor of Medicine. Eight years afterwards (1701) he was appointed lecturer on the theory of medicine at Leyden; and in 1705 he became physician to St Augustine's Hospital, and lecturer on the practice of medicine. From this date he commenced systematic clinical medicine, and gave clinical lectures twice a-week.

Boerhaave was professor of both chemistry and botany at the time he held the chairs of theoretical and practical medicine. He was therefore an encyclopædist. His mathematical and classical knowledge made him a man of extensive erudition, so that he was admirably calculated for the duty of reducing to order and systematizing the vast mass of scientific materials which had been accumulating during the preceding century. He placed physiological science in immediate relation with pathological research; he advanced practical medicine in all its departments; he was the first to make chemistry intelligible and delightful; and he largely developed botanical science. His system of medicine was eclectic, and, in some way or other, comprised the doctrines of the ancients, and the views of the iatro-mathematical and chemical theorists, together with his own speculations as a blending medium. He was the Galen, the Ebn Sina, the Fernel of his age. Already, therefore, a social epoch is ending, and another is about to commence. Before the end of the century the old institutions of European society were being swept away; the sacerdotal power was being annihilated, and the "goddess of reason" installed in the capital of France, in which, within a few years afterwards, the representative of that power was a captive to the military. Standing a while at these epochs to look back, we see that human affairs ebb and flow in grand tides as regularly as the tides of the ocean; for a while they seem to be restrained within safe limits, but one wave at last surely towers high above the rest, and falls with thundering and irresistible force upon the shore. In such a catastrophe, although beginning so favourably, the eighteenth century closed. The retrospect is a warning to the present generation.

Histories of medicine.

Mead.

In England, at the beginning of the eighteenth century, there were men who belonged to an earlier period than Boerhaave, but they were engaged in the same work. Mead, like Boerhaave, was the son of a Protestant minister. He was educated at Utrecht, studied medicine at Leyden, but graduated in 1696 at Padua, then a famous school. In 1703 he became physician to St Thomas's Hospital, and lecturer on anatomy at Surgeon's Hall. He was physician to George II. when Prince of Wales, as well as after he ascended the throne. He was the friend and successor of Radcliffe; was a learned man; wrote elegant Latin; read Greek and Arabic. He translated Rhazes's work on smallpox and measles from the only remaining Arabic manuscript, supplied to him by Boerhaave. Like Boerhaave, he had a vein of piety in his character, and to this probably was due his work entitled *Medicina Sacra*. Freind, the friend and contemporary of Mead, wrote a history of medicine. This was also done by Le Clerc about the same time.

Freind.

Le Clerc.

Sloane.

To this era belong also Sir Hans Sloane, Arbuthnot, Garth: all learned men, collectors of manuscripts, books, coins, and the like; chemists, botanists, poets, and the associates of the literary men of the time, as Dryden, Pope, Swift, &c.

Clinical medicine at Edinburgh. A.D. 1741.

British medicine is closely connected with the university of Edinburgh from the close of the first half of this century. A chair of theoretical medicine and botany had already existed for several years, when in 1713 a chair of chemistry was founded. The success and the example of Boerhaave at Leyden were not lost upon the university, so that shortly after his death a chair of clinical medicine was established on the same model. There was no medical school at either of the English universities, and the schools of the metropolis had no collegiate character, and were imperfectly organized. Rutherfurd and Monro were the first clinical professors at Edinburgh; the one lectured on surgery, the other on medicine. Whytt, the Monros, and Gregory were eminent teachers and writers at this time, or a few years subsequently, all being more or less under the influence of Boerhaave. But the chief man of the Edinburgh era was Cullen. He it was who formed the principal link between the doctrines of Boerhaave and those which arose during and at the close of the great revolutionary wars. Associated in early life with William Hunter (with whom he always maintained a warm friendship), Cullen, after various struggles, commenced in 1746 a course of lectures on chemistry in the university of Glasgow. In ten years after he occupied a similar chair at Edinburgh. In 1763 he succeeded to the chair of materia medica; in 1766 to the chair of institutes of medicine, or physiology, and resigned that of chemistry in favour of Dr Black. On the death of Rutherfurd he was associated with Gregory as alternate occupant of the chair of practical medicine. That distinguished physician did not live long, and Cullen became the sole professor. Cullen, like Boerhaave, systematized medicine, which his varied knowledge and great original powers enabled him to do well. In this work Van Swieten in Germany was his rival. But during his career the spirit of original research and investigation was awakened, and although he began with a compiled exposition of the doctrines of Boerhaave, he ended with a set of doctrines of his own. Albert von Haller, his contemporary, was at the same time laying the foundation of a new system of physiology, and pursued the same course. Up to 1747 Haller had used the *Institutions* of Boerhaave as the groundwork of his lectures on physiology; but in that year he published his *Primæ Lineæ Physologiæ*, and thenceforth, to the end of the century, he was one of the great lights of medicine. In London, at this period, John and William Hunter laid the foundation of the English school of physiology.

Physiology. Haller.

John and William Hunter.

Sacerdotal influence in 18th century.

At the same time that medicine began a fresh starting-point science and literature also took on a fresh development. Voltaire, although a few years senior to Haller, ran a course in philosophy and literature somewhat parallel. Religion at this time, as in the fifteenth century, had greatly ceased to be a reality, and had degenerated into ceremonial observances. The Jansenists, to which sect Voltaire's eldest brother belonged, had attempted a reformation, but were wholly scattered by persecution at the time that Boerhaave was at the height of his reputation; and the Roman priesthood had nothing better to offer to the people than a rigid adherence to ecclesiastical discipline and forms; that is, a submission to the power of the priests. In 1730 the celebrated actress Adrienne Lecouvreur was refused the rites of sepulture because of her profession. Voltaire wrote verses on the subject full of indignant invective, and from that time his whole life was a contest with the sacerdotal power. The reaction against the formality and laxity of the priesthood took place later in Great Britain than in Roman Catholic France, and did not begin, in fact, until the time of Wesley and others, when Jansenism was already extinct on the Continent, and the new reformation suppressed.

Natural science at the close of 18th century.

While religion decayed more and more, and the court, nobility, and higher clergy became more and more luxurious, science, as in former epochs, was continually progressing. An era like that of the close of the fifteenth century was, in fact, in full vigour; and a large number of scientific men were developing every branch of science. Medicine being so intimately related to every branch, largely participated in the movement. It would be a vain attempt to indicate in our limited space the progress made in each. It must therefore suffice to point out the grand advance made in what may be termed the science of matter, organic and inorganic, or chemistry. In Great Britain, Black, the friend of Cullen and Watt, led the way by his discovery of carbonic acid gas and the laws of heat; Cavendish discovered hydrogen gas; Priestly oxygen and other gases. These preceded Davy. On the Continent Bergmann and Scheele were working in the same direction, together with Guyton de Morveau, Lavoisier, Berthollet, Fourcroy, Klaproth, and others. A new nomenclature was given to the science, and it was re-cast from the foundation, and placed on a stable basis.

SECTION IV.—FOURTH PERIOD OF MODERN MEDICINE.

The first half of the Nineteenth Century.

Present era of European medicine.

At the commencement of the present century an improved chemistry, springing from the bosom of medicine, almost established modern civilization anew. On the one hand, numerous vital processes became intelligible, or at least it was at last possible to discover their nature by scientific research. Physiological science thus received an impulse, and therewith practical medicine, which even now is far from its maximum. On the other hand, the means of controlling nature, and of discovering her secrets, were placed within the hands of man. The laws of heat, as developed in steam, in metallurgy, and in manufactures; of electricity and galvanism; and of chemical affinity; have been applied to the practical uses of society, with results already so remarkable, that one mind would not suffice for their full expression. From the same causes, every kind of philosophical aid to research has been so improved that no branch of physical science is without good and appropriate instruments. Astronomy and meteorology have, however, most profited by them. The results of the last half century, as it regards medicine, will be best shown by a note, however brief, of the present state of medical science, and of the medical profession in the United Kingdom.

Present state of Medical Science in the United Kingdom.

Medical schools of the United Kingdom.

The extent of the teaching, and the number of subjects taught, constitute a measure of a science. The entire number of medical schools in the United Kingdom, not including Oxford and Cambridge, is 39. Of these, 12 are attached to the great hospitals of London, and 11 to those of large towns in England. There are 6 in Scotland, and 10 in Ireland. The entire number of recognised teachers in the various departments of Medicine cultivated in these schools is 493, being nearly 13 teachers to each school; besides tutors, private lecturers, and assistant lecturers. In the London schools there are 182; in those of the English provincial schools, 164; in Scotland, 68; in Ireland, 79. In Oxford and Cambridge there are 11 medical chairs, occupied by 9 professors. The entire number of students of medicine at these schools is about 3000, or about 1400 in England, 1000 in Scotland, and 600 in Ireland. With few exceptions, these institutions are wholly self-supporting, having no endowments from either private individuals or the state; in many instances the pecuniary remuneration is of trifling amount, and in some is even insufficient to meet the current expenses of the course of lectures.

Modern divisions of medical science.
Anatomy.

The subjects taught are from thirty to forty in number, and are divided as follows:—Anatomy, or the structure of the human body, has several subdivisions. First in order is general or descriptive anatomy, as the parent of all. Anatomical Demonstrations teach structure from actual dissection of the body. Histology demonstrates the minute anatomy or composition of structures as discernible by the microscope only. Comparative Anatomy (including palæontology) teaches the anatomy of the lower animals, with special reference to human anatomy and human physiology. Practical Anatomy is that branch which applies a knowledge of structure to the right performance of the operations of surgery. Pathological Anatomy points out the aberrations from the normal or healthy structure of the tissues or organs of the body.

Physiology.
Art of medicine.
Curative.

Anatomy is essential to a knowledge of healthy or of diseased function, or, in other words, to physiology and pathology. To both, but in particular to Physiology, are also subservient the departments of Organic Chemistry, or the chemical constitution and composition of living tissues and products in health and disease; Natural Philosophy in all its branches, except *medical meteorology*, which has not yet been taught separately; and Natural History, including Zoology and Botany. Pathology takes in a wide range, inasmuch as it includes the nature, causes, and symptoms of disease, or etiology, symptomatology, and doctrinal questions. The Art of Medicine is taught in the schools in numerous departments or subdivisions. First, as we have general or descriptive anatomy, so we have courses of general Practical Medicine, in which, in addition to general principles of treatment, the relief or cure of special visceral diseases, not included in special courses, is considered. This is Practical Medicine. Similar courses of instruction are given in Surgery and Obstetrics. All these, again, have their subdivisions. Thus, as subdivisions of practical medicine, Psychological Medicine teaches the nature and treatment of insanity, and *Epidemiology* treats of epidemical diseases. Surgery subdivides into Military *Surgery*, Operative *Surgery*, or practical training in the performance of surgical operations; and the surgery of the principal organs of sense, or Ophthalmic and Aural *Surgery*; to which may be added the treatment of diseases or defects of the teeth, or Dental *Surgery*. Obstetrics has the sub-departments of Operative Midwifery and Diseases of Children. Further, all the great departments of the art are systematically taught at the bedside in the principal hospitals. These are designated Clinical Courses. There are, therefore, courses of clinical medicine, surgery, and midwifery. Under this head Hospital Attendance, or "hospital practice," must be included.

Medicinal agents are largely used in every department of practice. These are included under the term Materia Medica, and courses of instruction are given as to their nature, composition, and uses. Subservient to materia medica are General Chemistry (comprising heat, galvanism, and electricity) and Medical Zoology and Botany. Therapeutics includes instruction as to the application and administration of every kind of remedy.

Preventive medicine.

The prevention of disease has not hitherto had that special attention devoted to it in the United Kingdom which it deserves, and as yet there are only three chairs of Public Hygiene. The subject has been usually included under etiology, practical medicine, and medical jurisprudence. In like manner, Dietetics (of which there are two chairs) has been usually included either in practical medicine or materia medica and therapeutics.

Political medicine

State medicine, or Medical Jurisprudence, is taught in all the schools, and discusses all questions of medical science and art bearing upon the administration of the law. Practical hygiene as to nuisances, disputed questions of mental capacity or moral responsibility on the ground of imbecility or insanity, and the causes and modes of violent death, are included under medical jurisprudence. Toxicology is one of its most important subdivisions, but has also relations to materia medica, pathology, and practical medicine.

The cultivation of all these departments of medicine, whether they be considered as branches of the science or of the art, is not possible without a knowledge of the means and modes of research available thereto. The principles

Instruments of research.

Medical logic.

of optics, acoustics, and hydraulics have been applied to the construction of several aids to the senses, of which the *microscope* and *stethoscope* are the chief. Skill in the use of these is part of the necessary qualifications of the efficient practitioner, and must be taught to the student. So also with the art of *chemical analysis*, whether inorganic, physiological, or pathological. The use of these and of other aids to investigation are taught in separate courses, or by separate teachers, in all the principal schools. In this department of medical art an immense advance has been made of late years. Perhaps from no quarter will so much advantage to medical science be derived, nor is it possible to divine to what extent our knowledge of human nature may be increased by the conjoint aid of those two potent instruments of research—chemical and microscopical analysis. After the training of the senses comes the training of the intellect. To this end a knowledge of LOGIC and of mental or moral philosophy is required. Only two of the medical schools of the United Kingdom (we except the universities) have chairs of logic. In this direction much has yet to be done in the culture of the professional mind. The defect being, however, felt, it will doubtless be remedied as opportunity serves.

Medical morals.

The medical profession has of late years endeavoured to define its duties and its rights. MEDICAL DEONTOLOGY or ETHICS has consequently received considerable development; and the fact that already there is one school in the United Kingdom having a chair of medical ethics, is an earnest that questions of professional *morals* are likely to have more and more attention directed to them.

Medical History.

The HISTORY OF MEDICINE, and its political and social relations, have also been treated in a separate course of instruction in one school. To the statesman and the intelligent layman it is a subject of great interest and importance. It cannot, however, be expected that these will occupy their minds with it when it is neglected by so large a number of the profession. The career of great conquerors, and the deeds of destroyers of mankind wholesale, are far more exciting themes than the silent unobtrusive doings of those who have preserved more lives than even the most ruthless conquerors have destroyed. The time will come, if modern civilization endures, when the moral grandeur of medicine will be acknowledged; then its progress will be felt to be one of the most interesting chapters of the history of mankind. That time, however, is not yet.

State of Medical Science Abroad.

Science breaks down the selfish barriers of states and nations, and gathers its cultivators into one great republic. This is particularly true of those who speak a common language and possess a common literature. Hence it is that the great republic of English medicine includes the medical schools of the United States of America and of the British colonies. Between these and the schools of the United Kingdom there exists the most intimate union, with a free interchange of knowledge. In the United States the number of schools and of teachers of medicine equals, if it does not exceed, that of the United Kingdom. It has been estimated that they are attended by 5000 students, and that 1000 of these graduate every year.

On the continent of Europe, the activity of medical life varies greatly according to the people or nature of the government. In France, Germany, Belgium, Holland, and Switzerland, medicine is cultivated as vigorously and as successfully as in the British or American schools. At Rome, Hippocrates is still commented on, as in the time of Leo X. In Italy generally (except Piedmont) and the non-German provinces of Austria, medical science is depressed; in Russia medical education, for the uses of the people at least, is by no means adequately developed, the few schools being wholly insufficient for so great an empire. Special departments of medicine have had a more diligent cultivation on the Continent than in the United Kingdom or the United States. This remark more particularly applies to medical police and public hygiene, which having had in the latter no encouragement from the state until of late years, has obtained no special attention. Late inquiries into the preventible causes of disease amongst the people of Great Britain, and the consequent establishment of boards of health, have laid the foundation for a new and most important department of practical medicine—the prevention of disease.

State of Medical Practice in the United Kingdom.

In all civilized countries the practitioners of the art are divisible into classes, the counterparts of which may be found in the United Kingdom, so that an analysis of British practitioners will apply, *mutatis mutandis*, to those of Europe and the United States.

Medical profession of the United Kingdom.

The practice of medicine is carried on in the United Kingdom by persons having various designations and qualifications. They may be divided into three classes. First are those who are "duly qualified" in virtue of having followed a prescribed course of study, and undergone successfully the examinations conducted by the collegiate or academical boards of examiners: this is the medical profession proper. Secondly, those who practise medicine as a business, yet have either not studied regularly or not at all, or having studied imperfectly, have no diploma or letters testimonial of having duly undergone an examination: these are empirics or "quack doctors." Thirdly, those who practise medicine as amateurs, or while engaged, ostensibly at least, in other pursuits: these are empirics also, but not professionally "quack doctors."

Qualified practitioners.

The qualified practitioners of medicine in the United Kingdom are known under various titles according as they follow one or another department of the art. The great proportion (about 20,000, or four-fifths) are *general practitioners* who, in accordance with the demands of thinly populated districts, or of the great majority of the population as represented by the middle and lower classes, minister to the people in every department of the art, and at the same time supply the necessary drugs and appliances. The metropolitan cities and the large towns have, in addition to these, a class of practitioners in special departments. There is the consulting or "pure physician," who excludes operative surgery, midwifery, and pharmacy from his practice. There is the "pure" consulting or operative surgeon, who practices neither midwifery nor pharmacy, but does not refuse his opinion in cases purely medical,—practising, in fact, as a surgical physician. The obstetric physician, while excluding pharmacy, and devoting himself more particularly to midwifery and the diseases of women and children, does not usually exclude the other departments of medicine. One or two minor departments of medicine and surgery are followed exclusively by a few individuals. The most numerous of these are the dentists, numbering about 1200 in the United Kingdom, who, however, are not for the most part "duly qualified" practitioners of medicine, but "mechanical" dentists. Of professed oculists and aurists exclusively there are very few, these usually combining general surgery with the practice of the special branch. In a similar manner, amongst physicians there are those who, having made a special study of special diseases, are specially consulted as to those diseases. Under this head are physicians skilled in the treatment of insanity and consumption, or diseases of the skin, the liver, the kidneys, the uterus, rectum, &c. The valuable discovery of anæsthetic medicines has called into existence another department, and this important class of remedies is already made a specialty in practice in the metropolis at least of the empire. In surgery a few "cuppers" still practise that branch of minor surgery exclusively. Chiropodists, or "corn-cutters," belong to the second class.

Sectarian practitioners.

Of late years a class of practitioners has arisen which, in so far as it is constituted of persons "duly qualified," may be designated *sectarian;* nevertheless, it is made up for the most part of charlatans. It comprises those who, whether duly qualified or not, practise medicine upon the basis of some exclusive dogma or principle, or with reference to some exclusive remedial agent. Legitimate medicine is catholic and eclectic; it has neither exclusive dogmas nor creeds; it requires its members to seek knowledge from every available source, and apply it in every available mode as may be demanded by the circumstances of the practitioner or the patient; the object of the exercise of the art being the relief or cure of the patient as promptly, safely, and pleasantly as possible, without any formal restriction as to the means or mode. This sectarian class therefore separates itself from the catholic profession by following professedly an exclusive method. Of the followers of Hahnemann (designating themselves *homœopathists*) there are reported to be about 300 in the United Kingdom. (See HOMŒOPATHY.) Of the followers of Priestnitz (the *hydropathists*) and of Mesmer (the *Mesmerists*) the numbers are much less. Indeed, the latter are not unfrequently homœopathists also.

Charlatan practitioners.

The "quack doctors" are a motley body, comprising every kind of specialty—worm-doctors, water-casters, bone-setters, astrologers, herbalists, "wise men," and "witch-finders" (who prove to be occasionally, as of old, professed poisoners and procurers of abortion), curers of syphilis and diseases of sexual organs (with hardly an exception a group of scoundrels), the "falling sickness," &c. In this class may be found also venders of secret remedies in connection with some absurd hypothesis, as *Coffin's* herbs, or *Morison's* pills; or itinerant practitioners of homœopathy, mesmerism, &c. The ranks of the quacks are also swelled by outcasts from the legitimate profession: men who are excommunicated either because of their vices or of their follies, and who have been morally punished by a *de facto* deprivation of professional intercourse with their brethren. In the third class of amateurs and others are comprised country clergymen, ladies having a taste for medicine, persons in private station with a smattering of knowledge, but especially the retailers and compounders of drugs, and professed nurses. Those who, when young, have abandoned or neglected the study of medicine as a profession, and have been led to follow other pursuits, are particularly apt to take up the irregular practice of it in after life.

Present Organization of the Medical Profession.

Its external organization.

The organization of the profession of medicine takes two directions,—an external and an internal. The external organization has reference mainly to the wants of the public or the state.

Public medical officers.

The army and navy have their respective medical officers; the public medical charities have their staff, comprising physicians, surgeons, obstetric physicians, apothecaries, oculists, aurists, cuppers; the medical relief of the sick poor engages the services of above 2000 practitioners. The public health is being gradually placed, in various towns and districts, under the cognisance of a body of special practitioners,—the medical officers of health; and the health of emigrants to the various colonies of the empire is committed to the care of surgeon-superintendents. These last are all practitioners in hygiene, as, indeed, are virtually the medical officers of the army and navy.

Its internal organization.

The internal organization of the profession has been determined by the operation of the great fundamental laws in virtue of which all human societies are constituted. So soon as the profession attained to a separate existence in the sixteenth century, the members thereof associated themselves together, and colleges of physicians were established. The humble assistants to the physicians of that era—the barber-surgeons and apothecaries—were also organized in like manner, but in guilds, which have developed themselves into colleges of surgeons or societies of apothecaries. Very lately the druggists or chemists (successors to the apothecaries of the last century) have organized themselves into "The Pharmaceutical Society;" and in like manner the surgeon-dentists propose to be incorporated into a college of surgeon-dentists. Nor has it been otherwise with the teachers of the different departments of medicine. With the development of the profession medical schools arose in the large towns, where only medicine can be taught in all its details—first in the metropolitan cities, then in the large manufacturing and commercial towns of the United Kingdom. Some of these are formally incorporated by royal charter; others, when firmly established, will undergo a similar change.

Medical corporations.

There are in all twenty medical corporate or licensing bodies in the United Kingdom. The colleges were originally founded in the metropolitan cities because the most active members of the profession were collected there in the greatest numbers. The same principle of combined action which led to their foundation has united the profession in other large towns, and in entire districts, in "medical societies" and "associations." These are virtually much of the nature of colleges; but the latter, starting from a legal basis and chartered rights, have gradually developed themselves into public authorities having control over the education of persons about to enter the ranks of the profession. That such control was, in the early history of modern medicine, most necessary and very useful, cannot be doubted; but the beneficial action of these colleges has not been had without some counterbalancing disadvantages. The corporate spirit is essentially contracted and narrow in its views; and the subdivisions in professional pursuits are apt to generate antagonism. The principal evil to which these colleges have given rise is, that the unity of all departments and branches of medicine, with reference to both its practical and philosophical relations, has been lost sight of. From this source has arisen much of the difficulty experienced for the last half century in the better organization of the medical profession.

Failure of attempts at legislation.

The repeated attempts made of late years to separate them legally by a sharp line of demarcation, and to arrange the practitioners of the various departments of the art in distinct legal classes, is but another form of the principle of caste, and which seems to have been strictly applied in ancient Egypt, where special practitioners abounded, and where they were restrained to their own department. Such legislation must always fail, for it is opposed by the ever vital principle of unity of the medicine. If rigorously carried out, decadence of the science and art is the inevitable result; if not rigorously carried out, the principle asserts its power as a disturbing agent. Consequently, whenever any special class of practitioners has arisen in this country, one or other result has followed. Having organized itself on the restrictive principle, its first efforts have been directed to a sharp limitation of its educational and municipal relations; but it has finally broken that limitation down, and returned to unity of teaching and of practice; otherwise it has gradually become more and more feeble.

Rise and fall of corporations.

The colleges of surgeons in the United Kingdom, first coming into existence as corporations of barbers and barber-surgeons, have constantly struggled upwards from that humble form of special practice, until at last their examinations and curricula of education are made to include, nominally at least, and their members practise, every branch of medical science and every department of medical art. The apothecaries' companies of London and Dublin have, in like manner, risen from corporations of drug-compounders and unlicensed practitioners across the counter, to be the examiners (virtually) of the great body of medical practitioners of the people. On the other hand, the physicians gradually lost their catholic character by refusing to perform the humbler services of the art, and by discountenancing the practice of them as ignominious. They have thus been as gradually changed into specialists themselves, with the effect of weakening their own influence, and retarding the progress of medicine. Hence, while the corporations of special practitioners have been constantly rising in power and influence in proportion as the principle of unity of medicine has been developed in them, the colleges of physicians and the medical faculties of the universities have been failing in power and influence in proportion as they have departed from that great vital principle. There is hardly a remnant of a medical faculty left in the two great universities of Oxford and Cambridge; while the College of Physicians of London, once so influential, and still in possession of stringent legal powers, is the least powerful of the medical corporations of London. In its palmy days, when it maintained the principle of unity, it could produce an anatomist like Harvey, could give its *imprimatur* to the works of a surgeon like Wiseman, and dictate the pharmacy of the kingdom. In later years, when to be associated in any way with pharmacy, surgery, or obstetrics, was discreditable to a Fellow, and to perform so simple an operation as venesection or vaccination was forbidden by its laws, the college dwindled into a small club of specialists, who weakly surrendered the actual government of the profession in England to a company of London apothecaries.

The medical faculty of the University of Edinburgh, happily for its fame and prosperity, has never abandoned the principle of unity of medical science and art. Candidates for its degree in medicine are required to study all those departments of science a knowledge of which is necessary to the successful cultivation, teaching, and practice of the art. They are also required to give evidence that they possess a competent knowledge of every department under the three heads of Medicine, Surgery, and Midwifery.

SECTION V.—THE FUTURE PROGRESS AND DEVELOPMENT OF MEDICINE.

The future of medicine.

Such, then, has been the past, and such briefly is the present condition of medicine. What will be its future condition? Two elements, external to medicine, will materially influence its future progress for good or evil: the one is the religious belief and condition of the people; the other the wealth and civilization. As to the former, human physiology is become in modern times what, in truth, the phrase designates—the science of human nature; and medicine the practical application of it. The advance of medicine in this direction is bringing it into collision with theological philosophy. We have seen how strenuously this has aforetime resisted the progress of natural philosophy, and we know how much discussion the entrance into its domain of geology and natural history has excited; what, then, will happen when a psychology, springing out of natural history and human physiology, confronts, not corrupt traditions only, but dogmatic and speculative philosophy, especially as applied to theology? Will the old ties of society resist its progress in the old world to its decay? and are we to look to the young states of the Western Hemisphere for unfettered freedom of discussion? or will a new reformation break forth in Europe, and herald a new era in religion, philosophy, and therewith in the medical sciences? Whichever of these may happen it may not be possible to divine; but few thinking men doubt that a great conflict of opinion is impending, if it be not already begun.

If we examine the condition of society more minutely with reference to these phases of development which we have traced as repeatedly occurring in successive epochs, we shall find that different parts of the world are in different stages of progress. It is necessary, therefore, to examine them in relation to each other.

In Western Europe the sacerdotal power has risen from its suppression at the beginning of the century, and is as busily as ever engaged in its old conflict with its old antagonist from all time—the spirit of free inquiry and free expression of opinion. Its success varies on different parts of the field of battle.

In the United Kingdom the event is yet hanging in the balance, and it is doubtful whether it will advance farther, or be made to recoil. The historical parallel of our age and nation is to be found in the age of the old Greek and the mediæval Italian republics. A widely-extended commerce is rapidly accumulating wealth; wealth is developing every branch of science and art. The national power and prosperity are continually increasing in every direction. This is the material side. On the religious and philosophical side there are both retrocession and progress. The sacerdotal power is seeking by all available means to resuscitate its glories of the mediæval age of Europe; while philosophy, whether natural or mental, is questioning the fundamental dogmas of the whole superstructure, but especially those branches included under geology, ethnology, and mental physiology.

In France freedom of opinion sleeps; the military power reigns, but leans upon the sacerdotal power, which it protects. All history shows that that state of society never continues. In which direction will the edifice fall? Upon that the fate of medical science in France depends.

In Central and Southern Europe the military power, and therewith the sacerdotal, is more supreme than in France. Change here is also inevitable, but its character may more easily be anticipated. The sacerdotal power is more dominant than in France—more antagonistic to science—more hated. The scientific element is feeble, but more popular; the military power will therefore probably lean to the latter, and support science and art.

In Eastern Europe the social condition is Asiatic; that is, almost purely patriarchal and sacerdotal. From that region a military sacerdotal power may fall upon Western Europe whenever the nations are torn by discordant religious factions, and success may be hoped for from the weakness of disunion; or that empire may itself fall a prey to civil discord, and be dismembered under military chiefs.

To the Turkish empire the last stage of decrepitude has come; but signs of reconstruction already appear; and if the enterprise and energy of commercial Europe again pour into it, as appears probable, Greek civilization will spring up once again in Asia Minor, and flourish amid the light of Christianity more vigorously than ever.

In Hindustan medicine is even now lifting its head; and the vivifying power of British freedom may happily restore to Asia more than its pristine greatness in science and literature.

On the American continent, and in the colonial empire of Britain, medicine will probably follow the fate of science in the mother country.

It will be seen at least from all this, that medicine, as the science and art of human nature, is of profound interest to the philosophic statesman. Looking at philosophy and religion from the medical point of view, he may also recognise in the present time one of those great eras in which a conflict of opinion shakes society to its foundations, and perils its very existence.

There are cheering indications that the practical English mind will compromise the quarrel, and philosophy and religion be once again combined for the welfare of man. On the one hand, science seeks in many ways to develope religious truth; on the other, not a few of the clergy are meeting science half-way. If by such a compromise all that is corrupt and traditional in Christianity be weeded out, and all that is true and practical in philosophy let in, we may anticipate the commencement of a new era of civilization.

But to this end it is necessary that the human mind be trained from childhood to a free use of its powers, and the great mass of the people be so enlightened as to be able to judge what is true or false, especially in relation to the nature of man. If a wise government could, single-handed, save a nation of ignorant and superstitious people, Marcus Aurelius, the patron of Galen, would have saved the Roman empire. Scientific truth must be amongst the people if it is to save the people.

The organization of the medical profession as students of human nature, and as the men who apply the science of human nature to the wants of mankind, is therefore a problem worthy the consideration of the philosophic and far-seeing statesman. Obscure as they may appear to the superficial observer, and contemptible as they are in the eyes of the mere man of the hour, medical science and the medical profession are working out great changes in the social condition of mankind, and not the less powerfully because silently and imperceptibly. Thus it is, indeed, that all great forces operate, whether in the physical or moral world; else a few fishermen could not have overthrown empires. The revealed action of a force consists often rather in the manifestation of its results than of its working.

The statesman who should succeed in so organizing medicine in all its departments as to give it a full and free application to the wants of society, and in aid of human progress, would surely take rank with the greatest benefactors of mankind. To the attainment of this object it is, however, of all things a primary necessity that a knowledge of human physiology,—that is, of the science of human nature,—be thoroughly diffused through every class of society. This knowledge is indeed necessary to the solution of all social questions; so true it is that "the proper study of mankind is man." (T. L.)

MEDINA, or El Medinah, a city of Arabia, in the province of El Hejaz, is situated in a wide plain forming part of the central plateau of Arabia, about 100 miles N.E. of Yambu, its port on the Red Sea, and about 260 N. of Mecca; N. Lat. 25. 15.; E. Long. 39. 30. Medina consists of a town, a castle, and a suburb nearly as large as the town. The main body of the town is of an irregular oval shape, and is surrounded by walls, built of granite and basalt, in a regular and substantial manner. Entrance is afforded by four gates, two of which, the *Bab el Misri*, or Egyptian Gate, on the W., and the *Bab el Jumah*, or Friday Gate, on the E., consist of large strong buildings, with double towers painted with broad stripes of red, yellow, and other colours. Along the walls, at short distances, there are placed smaller semicircular towers for the additional security of the city. The streets are irregular, narrow, dark, and unpaved, being covered with a soil consisting of hard, black earth. The houses are well built of a basaltic stone, and are generally two storeys high, with flat roofs. Those of the better sort are provided with a large open courtyard, where trees and water basins are frequently seen. The houses have latticed balconies, like those of most eastern towns; and the windows are extremely small. The number of the houses in the town and suburb is believed to amount to 1300, of which there are a few in a ruinous state. The castle, which is situated at the N.W. corner of the city, on a rock, is built like the walls and towers of the city, but in a stronger and more substantial manner. Its entrance is from the E. It is well provided with artillery, ammunition, and provisions, and has a garrison of 400; but it could offer no effective resistance to a force with a few guns and shells. To the S. and W. of the town is the suburb, separated from it by a broad road on the S., called the *Darb el Jenazah*, or Road of Biers, and on the W. by a plain called El Munakhah, about three-quarters of a mile in length by 300 yards in breadth. Although more extensive than the town, the suburb has not so many houses, as it is built in a straggling manner, with many open spaces. On the side next the town it is unprotected; but on the other side there is a wall, which is in a very ruinous condition. The houses in the suburb are for the most part arranged round large courtyards; they are low, and inhabited principally by the lower classes, who are employed to a great extent in agriculture. The suburb has several gates leading to the country; but the only one of these that is of any size is that at the W., called Ambari, a bad imitation of one of the gates of Cairo. The only buildings in the suburb worthy of notice are the governor's house, which is a plain building, situated near El Munakhah; and the five mosques, which are all very much alike,—neat stone edifices, surmounted by cupolas and minarets. Medina is especially famous for the Mosque of the Prophet, which is one of the two sanctuaries of Mohammedanism, and regarded by the Moslems as the second of the three most venerable places of worship in the world; the first being the mosque at Mecca, and the third that at Jerusalem. One of the sects of the Mohammedans even give it the precedence over Mecca, as being the place of burial of Mohammed; while others, on the contrary, do not approve of the high honour that is bestowed upon it by the generality of Mohammedans. The Mosque of Medina is an oblong building, about 420 feet long by 340 broad; and a great part of it, as is usual in Mohammedan mosques, is open to the sky. It is entered by five gates; and has five minarets, which, though not destitute of beauty and grandeur, have little regularity or uniformity. The open part of the mosque is surrounded by a colonnade; of which the northern side is unfinished, and will consist of granite columns and a pavement of marble. On the eastern side there are three rows of columns; on the western four; and the southern side has a much deeper colonnade, consisting of larger columns, and inclosing the tomb of the prophet. The columns of the mosque are very various in form and style, and are not distinguished by any architectural beauty or merit. In the centre of the open court there is a small square piece of ground inclosed by a wooden railing. This is called the Garden of Fatimah, the prophet's daughter, and it contains twelve date trees, of the fruit of which presents are sent to the sultan. To the S.E. of this inclosure stands the Well of the Prophet, supposed by some to have an underground communication with the Zem-Zem at Mecca; although by the majority of Moslem writers it is not held in much veneration, nor esteemed as a holy well. In the covered part of this mosque stands the Hujrah, which contains the tomb of Mohammed, and those of Abubekr and Omar, the first two caliphs. They lie with the heads pointing W. and the feet E., the head of each being opposite to the shoulders of the one immediately in front. These tombs are concealed from sight by a curtain of silk, which is renewed whenever it falls into decay, and upon the accession of a new sultan. It bears inscriptions in gold characters, to the effect that this is the tomb of the prophet and of the first two caliphs; and the position of Mohammed's grave is marked by a large rosary of pearls. Of the tomb of the prophet itself the accounts are very various; and as no one is allowed to approach it on account of the blinding light said to be emitted from it, the descriptions are not much to be relied upon. The popular account of the coffin being suspended

Medina del Campo.

between heaven and earth is a tale which is confined to foreigners, and has probably arisen either from the rude drawings of the mosque, or from a confusion between this and the rock said to be thus suspended in the mosque of Omar at Jerusalem. To the N. of these tombs is that of Fatimah, who is, however, supposed by many to be buried not here, but in the Bakia cemetery. Notwithstanding the universal tradition of the Moslems, it seems very doubtful whether Mohammed be really buried here at all, not only from the extreme discrepancy of the accounts given of the tomb by the learned, but from the great probability that the fable of the miraculous light surrounding it has been invented for the purpose of preventing any inquisitive visitor from prying too closely into the defects of the place. The mosque of Medina has been built and rebuilt six times at different periods; this having been rendered necessary by its frequent destruction by various accidents. The last time of its rebuilding was in 1710 A.D., when it was erected nearly in its present form. The establishment connected with the mosque is large. At the head of it stands the principal of the mosque, who has a salary of about L.300 a month. Under him is a deputy, a black eunuch, who has a pay of L.50. There is also a treasurer and sub-treasurer; besides a chief of the writers and an assistant, who keep the accounts of the mosque. There are also about 120 eunuchs who are under three *shaykhs*, and divided into three orders. Of these, the first act as doorkeepers, the second take care of the cleaner parts of the building, and the third clean the remaining parts, and prevent people from sleeping in the mosque. They get from L.2 to L.5 a month, besides the gratuities they may receive from visitors; and they are in general much respected. There are also a number of free servants, taken from the lower orders of the citizens, who are employed, in parties of 30 each, for a week, and have not much to do. There is also a *kazi* or judge, sent annually from Constantinople, who has under him three *muftis;* and the various other ministers of the mosque are very numerous. In the neighbourhood of Medina is El Bakia, the burial-place of the saints, of an irregular oblong form, inclosed by walls, and surrounded by plantations of palms. In the interior, however, there are no trees or flowers; and the buildings are simple, and by no means remarkable. The inhabitants of Medina are exempt from the payment of taxes, for the attendants of the mosque are paid partly by the sultan, and partly from the rents of the lands in different parts of the world which have been bequeathed to the sanctuary. A certain allowance is also given at Constantinople to any of the inhabitants of this city who may wish to travel. Commerce, however, is little carried on here; and the principal articles are grain, cloth, and provisions. In character the people of Medina are proud and indolent, looking down upon all strangers, and considering labour to be unfit for all but slaves. The climate of Medina is in winter comparatively severe; but in summer the heat is great, though not so oppressive as at Mecca. Throughout the winter rain falls frequently and in great abundance, so that the plain between the city and the suburb is at that season generally covered with water. Pop. from 16,000 to 18,000.

MEDINA DEL CAMPO, a town of Spain, in the province and 28 miles distant from the city of Valladolid, is situated in a plain on the left bank of the River Zapardiel, here crossed by two stone bridges. The partido is crossed by the high road between Madrid and Galicia, and that between Valladolid and Salamanca. The town is well built, and contains, besides remains of ancient convents, a collegiate church and six parish churches, two primary schools, and two hospitals,—the principal or general hospital, a spacious and handsome edifice. On the E. of the town is the celebrated Castilla de la Mota, still subsisting almost entire. The surrounding country produces wheat, barley, and wine; the latter, especially the white, of superior quality. There are also good pastures, which rear sheep, asses, and mules. The population is mostly agricultural, but there are manufactures of chocolate, earthenware, hats, and some other articles. Grain and wine are exported. The population amounted in 1848 to 2760.

Medina del Rio Seco ‖ Mediolanum.

MEDINA DEL RIO SECO, a town of Spain, in the province of Valladolid, from the city of which name it is distant about 24 miles, is situated on two eminences on the right bank of the Sequillo, here crossed by six bridges. The town was formerly surrounded by a strong wall, of which only remain three bastions and the six gates of the city; in the environs are several shaded walks (*alamedas*) much frequented. There are three parish churches: that of Santa Maria, an elegant Gothic edifice, Santiago and Santa Cruz, of Grecian architecture; two convents of Franciscan and Carmelite nuns, and five ex-convents,—that of St Francis being remarkable for the exquisite wood-carvings which it contains. The educational institutions are numerous; besides private establishments, there are two public schools of primary instruction, and two grammar schools. There are two general hospitals well endowed; also a foundling and a maternity hospital. Of the surrounding district, the low-lying lands are very fertile, the chief productions being grain, wine, and legumes of various kinds. The principal manufactures are of watches, locks, and smithwork in general; leather, and cloths of various kinds, especially baize, are also fabricated. The flour and bread of the town and district has a reputation in Spain. Formerly this town was a place of much importance in the internal commerce of the country, and its trade is still considerable. The baize of Siguenza is imported, dyed, and exported; and from various quarters come other articles of manufacture as to a common market. Its two annual fairs, on the 6th of April and 18th of September, were formerly celebrated. Pop. (1848) 4500.

MEDINA SIDONIA, a town of Spain, in the province and 21 miles from the town of Cadiz, is situated at an elevation of about 3000 feet above sea-level, in the form of an amphitheatre, on a spacious hill in the midst of a plain about 4 leagues in circumference. The town is well built, and the streets well paved and commodious. It has two parish churches; the one, Sta. Maria la Coronada, is a handsome Gothic building; that of Santiago is not so attractive. There exist two convents of nuns and five of monks. Of the ten schools in the town, four are public schools of primary instruction. There are two hospitals for the sick, and orphan and foundling hospitals. The surrounding district is traversed by the small rivers Alamo and Barbate, and contains also a number of small lakes or *lagunas*, and several mineral springs. From the mountainous nature of the country, there is more pasture than arable land. Much excellent fruit is grown. There are various brick and pottery works; coarse cloth is also manufactured to some extent. Pop. (1848) of town and district, 10,534.

MEDIOLANUM (*Milan*), the capital of Cisalpine Gaul, stood in the centre of the great plain of Northern Italy, at an equal distance between the Ticinus (*Ticino*) on the W., and the Addua (*Adda*) on the E. According to Livy, it was founded in the territory of the Insubres by the migratory Gallic hordes that crossed the Alps in the reign of Tarquinius Priscus. It was named after a village in Transalpine Gaul. Although the capital of the Insubres, Mediolanum does not seem to have passed beyond the condition of a village until it became subject to the Romans about 190 B.C. Then its pleasant site, in the middle of a large fertile plain, recommended it as a place of residence, and gradually raised it to importance. Strabo calls it "a considerable city;" and in the time of Pliny the Younger it had become a favourite seat of learning. During the wars with the barbarians of Pannonia, Germany, and Gaul, it was often the head-quarters of the Roman emperors. At length Mediolanum attained its highest prosperity when Maximian, about 303 A.D., chose it for his place of residence. It then became the abode of a refined and pleasure-seeking society. Temples, baths, elegant mansions, a palace, a theatre, a circus, and a mint, were speedily erected. It was now the capital of Northern Italy, and was thought worthy by Antonius, a poet of the fourth century, to hold the sixth place among his fourteen "Illustrious Cities." Mediolanum continued to be the seat of the imperial court until Honorius, alarmed at the approach of the Visigoths under Alaric, repaired, about 403 A.D., to the impregnable fortress of Ravenna. Its prosperity then began to decline, and was almost extinguished by the pillaging it suffered from Attila A.D. 452. However, it was still considered the capital of Northern Italy; and in 476 A.D. became the seat of the Gothic kings. Wrested from the Goths soon afterwards by Belisarius, it was retaken and reduced to ashes A.D. 539; yet it regained its prosperity in the middle ages, and retains it to the present day.

MEDITERRANEAN SEA (*Mare Internum*), the great inland sea which separates Europe from Africa, and washes the shores of the three continents of the old world, extends from the Straits of Gibraltar, where it communicates with the Atlantic, to the coast of Syria, and lies between 30. and 46. N. Lat., and between 6. W. and 36. E. Long., having a total length of about 2300 miles, and a breadth varying from 1100 or 1200 to about 80 between Cape Bon and Sicily, supposing the latter to be a part of the European continent. The modern name of the sea, derived from its land-locked position, was not used by the ancients. The Romans called it *Mare Internum* or *Mare Nostrum*, and its various parts had separate names, such as the Ægean, the Ionian, &c. By the Arabians it was known as *Bahr-Rúm*, or the Roman Sea. In the present day it is known to British sailors as the Straits; and the modern Greeks designate it the White Sea, in contrast to the Black Sea. The shores of the Mediterranean are as varied in character and outline as the countries which it washes. At its entrance stands the steep and lofty rock of Gibraltar on the European side, and that of Ceuta on the African, forming the pillars of Hercules, so famous in the ancient classics. The Spanish coast is low and fertile, with a great variety of mountains and plains in the background. It is irregular in outline, and has numerous harbours. Between France and Spain, the Pyrenees, with their high peaks, extend as far as the sea, and terminate in the bold headlands of Capes Norfeo and Creux. The coast of France is low, flat, and marshy, bearing marks of the sea having retreated considerably; but from the Bay of Hyères eastward it is of a more elevated nature. This character is continued along the shore of the Gulf of Genoa, where the sea is bounded by a steep, rocky coast, backed by the lofty mountains of the Apennines, among the recesses of which lie numerous fertile valleys. Very different in character is the W. coast of Italy, from Tuscany southwards to the confines of Naples. The whole of this region, which is known by the name of Maremma, consists of low pestilential swamps, terminating with the Pontine Marshes. The coast of Naples is remarkable for the beauty of its scenery, presenting a bold appearance and an outline much indented with gulfs and bays. To the E. of the Italian Peninsula, the Adriatic, an arm of the Mediterranean, stretches deep into the continent, and its two coasts present a remarkable contrast in nature and aspect. The western shore is low and shelving, with few harbours; while the eastern is bold and rocky, skirted with numerous islands, and containing many safe and excellent stations for anchorage. The coast of Albania, from Valona southwards, is skirted by the rugged and lofty range called Khemára, the Acroceraunian Mountains, so much dreaded by the ancient seamen. The classic shores of Greece, which are washed by the Mediterranean, present an irregular outline, with numerous mountain ridges descending to the sea, and forming large bays, behind which lie fertile valleys retiring among the mountains. The E. coast of Thessaly is skirted by the three famous mountains, Pelion, Ossa, and Olympus; and the N. and E. shores of the Archipelago present in general a bold and irregular outline. The N. shore of the Levant has also many bays and harbours; and, not far inland, rise lofty mountains, forming part of the snowy range of Taurus. The Syrian coast presents a very varied appearance, being in some places mountainous, but in others low and flat. The Egyptian coast is low and sandy; and a similar tract of country extends along the African shore of the Mediterranean as far as Raser-Tyn, where there is a mountainous district containing the site of the ancient *Cyrene*. Further to the W. are situated the Syrtes, which, though a source of terror to the ancients, have been ascertained by modern investigators to be by no means so difficult and dangerous of navigation as had been supposed. The coasts of Tunis are fertile and well cultivated, with numerous bays and harbours; and that of Algeria is remarkable for the beauty of its scenery and the fertility of its soil. The same general character belongs to the coast of Morocco, which extends from the borders of Algeria past the Straits of Gibraltar. A remarkable contrast is observable between the European and African shores of the Mediterranean; the former being irregular and much indented, whereas the latter are comparatively straight and uniform. The same difference, however, may be observed in general between the outlines of the two continents; and to this we may ascribe in some measure their different destinies, and the higher degree of civilization that has been attained by the European nations. The Mediterranean contains a great number of islands, of which the largest, arranged in the order of their size, are Sicily, Sardinia, Crete, Cyprus, Negropont (the ancient *Eubœa*), and Corsica; besides many of smaller size, lying singly or in groups, such as the Balearic, the Ionian islands, and those of the Archipelago. In several parts of the Mediterranean shores there are proofs of a change in the coast-line; and it has been a favourite theory that this sea, formerly a great lake, was brought into its present condition by the bursting of the barrier at Gibraltar from a violent rush of water either from E. or W. This opinion, however, has no greater authority than is due to a mere conjecture of more or less probability. The Mediterranean is divided into two well-marked basins. The western extends from Gibraltar to the narrow channel between Sicily and Tunis; while the eastern, comprising the Levant basin, with the Adriatic and Archipelago, extends from the coast of Tunis to that of Syria and Turkey in Europe, and is about twice the size of the other. Altogether, its area may amount to about 800,000 square miles. Its depth is in general very great, and in many parts as yet unfathomed; but between the E. and W. basins there is a remarkable belt of shallow water, showing that there is a sort of submarine elevation in this part between Europe and Africa. Soundings of no great depth were obtained all the way from Sicily to Tunis by Admiral Smyth; and the Adventure Bank, discovered by that navigator, forms a marked feature of this region, along with the Skerki Rocks, probably the same as those mentioned by Virgil as "saxa latentia:"—

> "Saxa, vocant Itali mediis quæ in fluctibus Aras."

In regard to the water of the Mediterranean there are several circumstances worthy of notice. It has been concluded, both from chemical analysis and from the observed facility with which salt is obtained from it, that the proportion of saline ingredients is greater here than in the ocean; and the ratio between the quantity of salt in the Mediterranean and the Atlantic respectively has been determined by M. Bouillon la Grange, after a series of experiments, to be 41 to 38. The phosphorescent brilliance of this sea is now known to be produced by noctilucous animalcula, but it is not peculiar to the Mediterranean. The prevailing colour of the water is a deep blue; but in the Adriatic it is of a greenish hue, and towards the E. it approaches purple.

The Mediterranean receives many large rivers both from Europe and Africa, of which the most considerable are the Ebro, Rhone, Po, and Nile. And, in addition to the rivers by which it is fed, it derives a considerable supply of water from the strong current which always sets in from the Black Sea and the Sea of Marmora through the Dardanelles, and also from the current which sets in from the Atlantic through the Straits of Gibraltar. But as its level continues unchanged, it would seem that the water entering it is not more than sufficient to supply the waste occasioned by evaporation. Some indeed have supposed that there is an under-current setting outward through the Straits of Gibraltar; but this opinion does not seem to rest on solid and trustworthy evidence. A calculation made by Halley of the quantity of water removed by evaporation showed it to be sufficiently great to preserve the level; but, according to Smyth, the grounds for this theory are insufficient and incorrect. But, however it may be accounted for, there can be no doubt of the fact, that the system of compensation is accurately adjusted between the water coming in and going out. The principal current of the Mediterranean flows to the E., from the Atlantic, along the African coast, till it reaches the coast of Syria and Asia Minor, when it returns westward along the northern shores of the sea. In the middle of the Mediterranean, between Sicily and Africa, the currents are very irregular, varying according to the changes of the wind and weather. In the Adriatic the current runs up the Dalmatian and down the Italian shore with considerable steadiness. In the Archipelago the prevailing direction is from the N.E., caused by the water of the "Pontic Sea"—

> "Whose icy current and compulsive course
> Ne'er feels retiring ebb, but keeps due on
> To the Propontis and the Hellespont."

The Mediterranean is subject to tides, though these are very inconsiderable in comparison with other seas, and very irregular in their motions. This fact, however, cannot be taken as any objection against the true theory of tides discovered by Newton; the weakness of those in this sea being a necessary consequence of its comparatively small extent, and of the narrowness and position of its communication with the ocean, which render it impossible for the level at any part to be considerably raised by the influx of water through a passage which is narrow and in a direction opposite to the course of the great tidal wave of the world.

The prevailing winds in the Mediterranean are those which blow from N. and W.; but in the spring months S.E. and S.W. breezes are most frequent. Among the most remarkable winds in this sea is the *mistral*, a cold wind which comes from the snows of the Alps, and rushes southward, over Provence and the valley of the Rhone, to the sea, blowing with great violence and impetuosity, and forming one of the scourges of Provence. Of a very different character is the much-dreaded *scirocco*, a hot wind blowing from the S.E. over the sultry deserts of Africa. This blast is felt on the S. coast of Sicily; but having passed over a large extent of water, it is not so oppressive there as when it has again become heated by traversing the island; and it is especially felt at Palermo on the N. coast. Another wind, very dangerous to ships, is the *bora;* which, like the ancient *boreas,* whence it derives its name, is a N. or N.E. breeze. It is frequently accompanied with thunder, lightning, and rain; and sometimes lasts as long as three days, though its usual duration is fifteen or twenty hours. Water-spouts are of frequent occurrence in the Mediterranean, and are much dreaded or at least carefully avoided, by cautious navigators. They are believed to be the result of the rotatory motion produced in the atmosphere by whirlwinds, with the addition of the electricity of the air. Electrical phenomena are common in this sea; and one of the most remarkable and famous of these appearances consists of the balls of fire which play round the masts and rigging of ships, called by the ancients *Castor and Pollux*, and by the modern seamen of the Mediterranean, *Corpo Santo*, or *St Elmo's fire*. These meteors are harmless; but when only a single ball appears it is believed to be a bad omen. (See *The Mediterranean; A Memoir, Physical, Historical, and Nautical,* by Rear-Admiral William Henry Smyth, K.S.F., D.C.L., London, 1854.)

The Mediterranean is the theatre of a very extensive trade. Many large commercial cities, such as Barcelona, Marseilles, Genoa, Leghorn, Naples, Palermo, Venice, Trieste, Syra, Smyrna, Alexandria, and perhaps we may add Constantinople, are built on its shores; and there can be no doubt that its trade will increase with the increasing civilization of the extensive countries round the Black Sea and its eastern shore, and the opening (which cannot be long delayed) of the old route to India through Egypt. In the meantime we take leave to subjoin, in illustration of what has now been stated, the following account of the exports from Great Britain to the Mediterranean previously to the interruption occasioned by the Russian war, and in 1856:—

Account of the Declared Value of the Exports of British Produce and Manufactures to the several Countries and Territories (exclusive of France and Spain) bordering on the Mediterranean and Black Sea, in the years 1849, 1850, *and* 1856.

The Mediterranean is interesting, not only from its geographical and physical character, but from the associations which connect it with the history, and the influence which it has exerted on the trade, condition, and prosperity of mankind in general, and especially of the nations situated along its shores. Adam Smith has shown how well it was fitted to promote the early commerce and navigation of the ancient world; while the riches and prosperity of the nations by whom it was navigated, and their intercourse with each other, increased their knowledge and enlarged their minds. Thus the Mediterranean became a most important means of the civilization of the ancients; and even the great development of literature, poetry, and philosophy, for which these nations were distinguished, may be believed to have had some connection with these circumstances, when we remember that the Phœnicians, the earliest commercial people in the world, had the reputation of being the inventors of letters; that the father of verse as well as the father of history in Greece had evidently travelled much on the shores of the Mediterranean; and that the birthplace of Greek philosophy was in the Asiatic colonies, which were distinguished also for trade and seafaring activity. However this may be, it is certain that the most civilized of ancient nations dwelt along the Mediterranean: Egypt, Phœnicia, Greece, Carthage, Rome, each in turn, played their part in history; and if in modern times this sea is no longer the seat of the world's masters, it is partly because new regions and a wider sphere having been opened mankind have quitted this, the cradle as it were of their young energies; and partly also because a great part of the shores of the Mediterranean have been long subject to the blighting and disastrous influence of the Turkish sway.

MEDOC, a district of France, formerly comprised in the old province of Guyenne, and now forming the N.W. portion of the department of Gironde. This district is particularly famous for its claret wines.

MEDUSA, in fabulous history, one of the three Gorgons, and daughter of Phorcys and Ceto. (See GORGONS.)

MEDWAY (the ancient *Vaga*), a river of England, which rises in the S.E. of the county of Surrey, near East Grinstead, flows in a winding N.N.E. direction across the county of Kent, and joins the Thames by a broad estuary at Sheerness. It passes Tunbridge and Maidstone, and becomes at Rochester and Chatham a tidal stream of great depth, spreading out into a broad estuary, and forming an important harbour for the British navy. It is 60 miles in length, for more than 40 of which it is navigable.

MEEANEE, a town of India, situated in the British province of Sinde, on the banks of the Fulailee branch of the Indus, and 6 miles N. of Hyderabad. Here on the 17th February 1843 Sir Charles Napier gained a brilliant victory over a Beloochee force of vast superiority in point of numbers, headed by the ameers of Sinde. The British troops amounted only to 2800 men, with twelve pieces of artillery; that of the enemy consisted of 22,000, with fifteen pieces of artillery. After a close and obstinate engagement for above three hours, during which the Beloochees showed desperate valour, the right of their position was carried by the Anglo-Indian cavalry, and their army totally routed, losing artillery, ammunition, standards, and camp, with considerable stores and some treasure. The British loss amounted to 256 men killed and wounded; that of the enemy was estimated at 5000. Six of the principal ameers surrendered themselves immediately after the battle. Lat. 25. 26., Long. 68. 26.

MEERMAN, GERARD, a learned writer on law, was born at Leyden in 1722, and was early distinguished for his erudition. In 1748 he was nominated pensionary of Rotterdam; and in 1757 he was sent on an embassy to Great Britain. He died at Aix-la-Chapelle in December 1771. The principal works of Gerard Meerman are *Novus Thesaurus Juris Civilis et Canonici*, in 7 vols. folio, 1751-54; and *Origines Typographicæ*, 4to, 1765. In the latter he attempts to prove that his countryman Lawrence Koster was the inventor of the art of printing. To the former an eighth volume was added by his son.

MEERMAN, *Jan*, an eminent Dutch scholar and statesman, was the only son of the subject of the preceding article, and was born at the Hague in 1753. Scarcely was he ten years old when he published, with the aid of his teacher, a translation of the *Marriage Forcé* of Molière. He afterwards studied under Ernesti, at Leipsic, and under Heyne at Göttingen. On his return from a tour through Saxony and Prussia, he repaired to Leyden to finish his studies, and there he received the diploma of Doctor of Laws in 1774. Jan Meerman was a great tourist, and published full accounts of the observations he made during his travels through almost every country in Europe; yet at the same time he had become so conspicuous for his learning and public activity, that on the accession of Louis Bonaparte in 1806 to the throne of Holland, he was appointed director of the fine arts, and minister of public instruction. These offices he discharged with great zeal and success. In 1810, when Holland was incorporated with France, Meerman became count of the empire and senator. In the latter capacity he was a thorough-going supporter of Napoleon. He died at the Hague on the 15th August 1815. Meerman's principal works are,—*Specimen Juris Publici de Solutione Vinculi quod olim fuit inter sacrum Romanum Imperium et Fœderati Belgii res publicas*, 4to, Leyden, 1774; *History of William, Count of Holland, and King of the Romans*, in 5 vols. 8vo, 1783-97; and *An Historical Account of the North and North-East of Europe*, in 6 vols. 8vo, Hague, 1805-6.

MEERUT, a town of Hindustan, and the principal place of the British district of the same name, is situated upon the western bank of the Kalee Nuddee. It has been from ancient times a place of considerable consequence, and is mentioned amongst the early conquests of Mahmoud of Ghizni in the year 1018. In 1399 it was taken and destroyed by Tamerlane. It was afterwards rebuilt; and when this part of the N.W. provinces came into the possession of the British, it was fixed upon as the capital of one of the districts into which the British possessions in the Doab of the Ganges and Jumna were subdivided. In 1809 it was made one of the principal military stations under the Bengal presidency; and more recently the head-quarters of artillery for the same presidency. It has recently (1857) acquired an infamous celebrity as the place where the mutiny of the Bengal army, which spread with fearful rapidity, first broke out. It was here that the men of the 5th regiment of Bengal cavalry suddenly fell upon their officers, and then released 70 of their comrades who had been imprisoned, under sentence of court-martial, for insubordinate conduct. It was here that the first massacre of Europeans, including women and children, took place; and it was from this place that other native infantry regiments, joining the mutinous 5th cavalry, were allowed to escape to Delhi, and, for the first time in the history of British India, to set at defiance the power and authority of the British government. Meerut is 32 miles N.E. from Delhi; Long. 77. 46. E., Lat. 29. 1. N. The district of which this place is the capital lies between Lat. 28. 33. and 29. 17., Long. 77. 12. and 78. 15. It is about 57 miles in length and 48 in breadth, and has an area of 2332 square miles.

MEGALOPOLIS (*Sinano*), the later capital of Arcadia, stood on the River Helisson, in the middle of a spacious plain on the N.W. border of Arcadia. It was founded at the suggestion of Epaminondas in 370 B.C., shortly after the battle of Leuctra, and was intended to be the capital and stronghold of the Arcadian confederation against Sparta. After the lapse of three years it was finished, and was peopled by settlers drawn from forty different towns. Yet, owing to the inadequate number of its inhabitants, the "great city" never attained to the importance that had been expected. On the overthrow of the Theban supremacy it was forced to strengthen itself against Sparta by an alliance with Macedonia. At length, in 222 B.C., it was surprised by the Spartan king, Cleomenes III.; the greater part of its magnificent structures were rased to the ground; some of its inhabitants were put to the sword, and the rest escaped with difficulty to Messene. Soon afterwards, however, the fugitives returned and rebuilt their city. But Megalopolis never recovered its former importance; and in the time of Pausanias it was little else than a field of ruins. It was the birthplace of the great general Philopœmen, and of the historian Polybius.

MEGARA, the chief city of the Grecian state Megaris, was built on the hills about a mile from the shore of the Saronic Gulf. According to the traditions narrated by Pausanias, the town was founded by Car, the son of Phoroneus. In the course of twelve generations Lelex succeeded to the government, and conferred upon the inhabitants the name of Leleges. A subsequent king, Nisus, called the city Nisæa, and gave the same title to the port which he built on the sea-shore. In the same reign, however, the name was changed to Megara, in honour of Megareus, son of Poseidon, who had been summoned from Bœotia to assist Nisus, and had died in the city; but the port-town still continued to be called Nisæa. These accounts, however, have not been shown to be out of the region of mere fable; and the first fact in the early history of Megara is, that it was included within the ancient limits of Attica. During the reign of Codrus it was wrested from the Athenians by the Dorians; and after remaining for some time in subjection to Corinth, it finally asserted its independence. The favourable situation of Megara now speedily raised it to the height of commercial prosperity. The great highway between the Peloponnesus and Northern Greece running through its territory, brought all the traffic of the country within its reach; and its proximity to the Saronic Gulf on the one side and to the Corinthian on the other, gave it facilities for trading both with the East and the West. To what prosperity Megara had attained in the sixth century before the Christian era is shown by the important colonies it planted. It founded Megara Hyblæa in Sicily in 728 B.C., Astacus in Bithynia in 712 B.C., Chalcedon in 674 B.C., Byzantium in 657 B.C., and several others. But as a result of the commercial opulence, the lower classes became the most influential part of the community; and after a severe contest, the Dorian governors were compelled to resign their power to a demagogue, Theagenes. This potentate was expelled about 600 B.C., and a lengthened struggle between the democracy and aristocracy ensued. In 455 B.C. the Athenians, being summoned to the assistance of the Megarians against the Corinthians, built the two long walls connecting Nisæa with Megara. On the outbreak of the Peloponnesian war Megara became an ally of the Spartans. But the Megarians paid dearly for their hostility to Athens. During seven years their fields were annually wasted, their city was besieged, and their port, Nisæa, was blockaded. However, in the eighth year of the war they were relieved by Brasidas the Spartan general, and succeeded in establishing a firm and exclusive oligarchy. After this period the historical notices of Megara are few and unimportant. It was again under a democracy in 357 B.C. It surrendered without a struggle to a Roman army under Metellus; and in the time of Strabo it was a Roman colony. Megara was celebrated for its philosophical school, founded by Eucleides, a disciple of Socrates. It is now an insignificant village, with about 1000 inhabitants.

MEGARIS, a district of ancient Greece, in the northern part of the Isthmus of Corinth, was bounded on the S. by the Saronic Gulf, on the W. by Corinth and the Corinthian Gulf, on the N. by Bœotia, and on the N.E. by Attica. It extended along the coast for about 25 miles; and its extreme breadth was estimated by Strabo to be 120 stadia. With the exception of the "White Plain," in which Megaris stands, the district is crowded with rugged chains of hills. The Geraneian Mountains extend eastward from the shores of the Corinthian Gulf, sending out offshoots through the entire country, and sinking gradually as they approach the Saronic Gulf. Originally Megaris was inhabited by Æolians and Ionians, and formed part of Attica. It subsequently fell under the dominion of the Dorians. As it contained no town of any importance except Megara, the history of that city is the history of the district. (See MEGARA.)

MEHEMET ALI, or MOHAMMED ALI, or MOHAMMAD 'ALEE, Pasha of Egypt, was born in 1769,—rose by military energy to the pashalic of Cairo in 1806,—seized upon Syria in 1830,—but was deprived of it by the sultan in 1840, after the intervention of the European powers, when the pashalic of Egypt was made hereditary in his family. He administered the affairs of Egypt till 1848, and died in 1849, aged eighty years. (For a full account of his career, see the article EGYPT.)

MEHIDPOOR, a town of Hindustan, in one of the outlying possessions of Indore, or the territory belonging to the Holkar family. It is situated on the banks of the River Seepra, and is celebrated as the scene of the decisive victory obtained by the British in 1817 over the army of Holkar, whose power was in consequence effectually and irretrievably overthrown. The loss on the part of the British amounted to 174 killed and 604 wounded; that of the Mahratta chief was estimated at 3000 men. In the treaty of Mundesor, concluded shortly after, Holkar submitted to terms which reduced him to the condition of an insignificant and dependent power. Lat. 23. 30., Long. 75. 40.

MÉHUL, ÉTIENNE HENRI, one of the most remarkable composers of France, was born at Givet, in Ardennes, on the 24th of June 1763. His father was a cook, and destitute of education. Young Méhul's first lessons in music were derived from a poor blind organist of Givet, and such was the boy's aptitude, that, when ten years old, he was appointed organist of the Franciscan church there. In 1775 an able German musician and organist, Wilhelm Hanser, was engaged for the monastery of Lavaldieu, a few miles from Givet, and Méhul became his occasional pupil. In his sixteenth year Méhul was taken to Paris by a military officer, and placed himself under Edelmann, a good musician and harpsichord player. Méhul's attempts at instrumental composition in 1781 did not succeed, and he therefore turned his attention to vocal music, and especially dramatic. The great composer Gluck received him kindly, and gave him advice in his studies. After various delays and disappointments during his efforts for six years to obtain, at the Grand Opera, a representation of his *Alonzo et Cora*, he offered to the Opera Comique his *Euphrosine et Corradin*, which being accepted and performed in 1790, at once fixed his reputation. The critics acknowledged in it great energy of dramatic expression, and a brilliant instrumentation; but objected to a general want of graceful melody, and to heaviness and monotony in the harmony and accompaniments. His opera of *Stratonice* had great success. After several other operas which did not succeed, his *Adrien* appeared, and added much to his fame. He had been appointed one of the four inspectors of the Paris Conservatory, but that office made him feel continually the insufficiency of his early studies, and the falseness of his position. *Timoléon*, *Ariodant*, and *Bion* followed *Stratonice*, with various success. *Epicure* was composed jointly by Méhul and Cherubini; but the superiority of the latter was evident. Méhul's next opera, *L'Irato*, failed. After writing a number of other operas, his health gave way, from an affection of the chest. He composed in all forty-two operas, besides ballet music, and songs for festivals of the republic. After lingering for several years, he died on the 18th of October 1817. Among Méhul's contemporaries and countrymen may be mentioned Dalayrac, Grétry, and Monsigny, as successful and popular operatic composers. Hérold, another French composer of celebrity, was a pupil of Méhul, and died in January 1833. Boieldieu, Halévy, and Auber, have added much to the reputation of the more modern school of French opera composers. (G. F. G.)

MEHWAS, a district of Hindustan, in the province of Gujerat, situated on the S.E. bank of the Nerbudda River. It literally signifies the residence of thieves, which character formerly attached to the inhabitants, who live by plundering their neighbours. Every man who in this turbulent region could muster twenty horseman, considered himself as an independent chief, and set out on a marauding expedition. When the political control over the Mehwas chiefs became vested in the British government, the best provision practicable was made to meet these evils; and as in such a country crimes attended with violence were most to be apprehended, steps were taken for their suppression with a strong hand, and for the introduction of a well-administered system of criminal justice, to which the country was previously a stranger. It was decided that all persons charged with capital offences, such as gang-robbery, or murder, within the territories of these chiefs, should be tried before a court of justice, in which the British resident and three or four chiefs should sit as assessors. This court was established in 1839, and the results, it is stated, have been found satisfactory.

MEIBOM, or MEIBOMIUS, MARC, a learned philologist, was born about 1630, at Tönningen in the duchy of Schleswig. His first work, a collection of seven ancient authors on music, was dedicated to Queen Christina of Sweden, and procured for him an invitation to the court at Stockholm. There he lived for some time in the enjoyment of a pension from his royal patroness. At length, having undertaken, at the request of the queen, to conduct a concert in the manner of the ancient Greeks, he was so much offended at the roars of ridicule and laughter which his fantastic performance elicited from the courtiers, that he left Sweden immediately. He bent his steps towards Denmark, and there Frederick III. appointed him his librarian, and gave him a chair in the university of Upsal. But in a short time some cause of discontent induced Meibom to vacate his offices, and to repair to Holland. His next appointment, the professorship of belles lettres in the university of Amsterdam, was taken from him after the lapse of a year, in consequence of his fastidious aversion to teach the sons of burgomasters. After sojourning in France for some time, he repaired to England in 1674, intent upon publishing a new edition of the Hebrew Bible; but his whimsical emendations on the sacred text met with no approval, and he was compelled to return to Amsterdam without having accomplished his cherished project. Towards the close of his life he was driven to sell a part of his library to supply his necessities. Marc Meibom died at Utrecht in 1711. The following is a list of his works:—*Dialogus de Proportionibus*, folio, Copenhagen, 1655; *Antiquæ Musicæ Auctores Septem*, in 2 vols. 4to, Amsterdam, 1652; *De Veteri Fabrica Triremium*, 4to, Amsterdam, 1671; *Davidis Balmi Duodecim et totidem Sacræ Scripturæ Veteris Testamenti Integra Capita, prisco Hebræo Metro restituta*, folio, Amsterdam, 1698. An edition of the ancient Greek mythologists, 8vo, Amsterdam, 1688, and an edition of the *Lives of the Philosophers*, by Diogenes Laertius, in 2 vols. 4to, Amsterdam, 1692.

MEINERS, CHRISTOPH, a philosopher, historian, and literateur of Germany, was born at Warstadt, near Otterndorf in Hanover, in 1747. Passing from the gymnasium of Bremen, where he left behind him a reputation for extraordinary ardour, he entered the university of Göttingen, where he completed his education, and afterwards received the appointment of professor of philosophy in 1771. Although as a student he despised the lectures of his masters, despite their acknowledged eminence, preferring to study alone and by the aid of books, yet as a professor his influence and success were by no means remarkable. He was subsequently appointed vice-rector of his university, and became one of the most active members of the Royal Society of Göttingen, established a short time before by the illustrious Haller. He received the title of Aulic Counsellor from the Hanoverian government; and had the honour to be appointed by the Emperor Alexander to the delicate mission of selecting professors capable of naturalizing science and letters in the empire of Russia,—a task which Meiners discharged to the entire satisfaction of his imperial patron. He died on the 1st of May 1810. Meiners occupies a higher position as a writer than as a philosopher. The intellectual independence of his earlier years was more apparent than real when he attained to maturity. The success of his writings is chiefly attributable to two causes,—their popular style, and their practical character. His style, besides being very clear and methodical, is characterized by a happy combination of candour and good sense, which pleases the reader and awakens his interest. On meeting with a speculative problem, his first consideration is not how to subject it to a thorough-going analysis, but rather how to discourse about it in an easy, popular manner. He accordingly waged a perpetual war upon the disciples of Leibnitz and Wolf, and the partisans of Kant, denouncing them as unintelligible scholastics and dreaming mystics. Philosophy in the hands of Meiners ceased to deal with the recondite and the abstract; it became an agreeable piece of study, not requiring much thought, and doing no violence, by an abstract terminology, to the taste of the most fastidious. The only genuine philosopher of the eighteenth century he believed to be Rousseau; and he spared no pains in endeavouring to propagate his doctrines and excuse his errors. Meiners laboured to prove, from ancient and modern history, that public prosperity and individual wellbeing are alike inseparable from enlightenment and virtue. His writings exerted considerable influence in Germany, and his views of the physical and moral inferiority of the Negro race used to be triumphantly quoted in the British Parliament by the defenders of the slave trade.

Of the works of Meiners, which were very voluminous, the principal are,—*Historia Doctrinæ de vero Deo*, 1780; *Gesch. des Ursprungs, &c., der Wissenschaften in Griechenland u. Rom.*, 3 Bde., 1781; *Gesch. der Schönen Künste*, 1787; *Gesch. des Verfalls der Sitten, &c.; der Römer*, 1791; *Gesch. der Religionen*, 1806–7; *Untersuchungen über die Denk. u. Willenskräfte*, 1806.

MEININGEN, a town of Central Germany, capital of the duchy of Saxe-Meiningen, is situated on the right bank of the Werra, 33 miles E.N.E. of Fulda. It stands in a valley, surrounded by wooded hills, and is protected by walls and ditches. The old part of the town is not well built; but the newer portion is regular and handsome. The principal building in the town is the palace of the Dukes of Saxe-Meiningen, where they have resided since 1681. This building contains a gallery of paintings and engravings, a museum of natural history, and a large library. Besides this, Meiningen contains the house of assembly for the states of the duchy, three churches, several schools and hospitals, and a theatre. The manufactures of the place consist of woollen and linen stuffs, leather, &c. The town has ten annual fairs, but the trade is not very considerable. Pop. 6451.

MEISSEN, a town of Saxony, circle of Dresden, occupying a picturesque position on the left bank of the Elbe, 15 miles N.W. of Dresden. The town is for the most part ill built, and the streets are narrow and gloomy. The principal building is the cathedral, a fine Gothic edifice, surmounted by a spire adorned with elegant open work, and containing numerous ancient monuments of the ancestors of the Saxon line of princes and others, as well as several pictures by Albert Durer and Cranach, among which are portraits of Luther, his wife, and his friend Frederick, the elector of Saxony. Close to the cathedral is the Princes' chapel; and not far off stands the palace of Albrechtsburg, formerly the residence of the margraves, but now used as a porcelain manufactory, from which the finest articles are produced. On a high rock, near that on which the palace stands, and joined to it by a stone bridge, stands the former convent of St Afra, now used as a school. There are also several hospitals and other charitable and educational institutions in Meissen. The chief branches of industry pursued here are the manufacture of porcelain, employing 500 or 600 hands, and the making of wine. There are also sugar refineries, tanneries, and dyeworks, but they are not of much importance. Pop. 8914.

MEISSNER, Augustus Gottlieb, a popular German writer, was born at Bauzen in Upper Silesia in 1753. After studying three years at Wittenberg, he went to study law at Leipsic; and afterwards held the offices of chancery-clerk and keeper of the archives at Dresden. In 1785 he was appointed professor of æsthetics and classical literature at the university of Prague; and in 1805 became director of the High School at Fulda, where he remained till his death in 1807. In addition to some translations from the dramas of Molière and Destouches, Meissner wrote the operas of *Das Grab des Mufti*, *Der Alchymist*, *Die Schöne Arsene*, which enjoyed a fair degree of popularity; but the work which rendered him a general favourite with the public was his "Sketches" (*Skizzen*, Leipzig, 1778-96), extending to fourteen series, and made up of essays, tales, and dialogues, &c., written with much lively vigour and quaint pleasantry, and displaying subtle powers of observation and clear-sighted sagacity. These pieces, besides charming the readers of light literature in Germany, attracted the notice of foreign readers also, and were translated, in whole or in part, into French, Danish, and Dutch, and into English in Thompson's *German Miscellany*. Meissner followed up the plan of these sketches in his Tales and Dialogues (*Erzählungen u. Dialogen*, 1781-89), which afford very agreeable and often highly instructive reading. Besides being an extensive contributor to a great number of literary journals, Meissner produced a series of romances of a historical and biographical nature, the principal of which are, —*Bianca Capello*, 1785; *Masaniello*, 1785; *Spartacus*, 1792; *Epaminondas*, 1798; *Das Leben des Julius Cäsar*, 1799.

MEKLONG, or Mekhlong, a town of Siam, is situated at the mouth of a river of the same name, 30 miles S.W. of Bankok. It has a harbour for small vessels, and the trade is considerable. Pop. from 10,000 to 13,000.

MEKONG, Menam-kong, or Cambodia, a river of Asia, which is supposed to rise in the Chinese province of Yunnan, near the frontiers of Thibet, and which flows S.E. through a fertile valley till it falls into the Chinese Sea by several mouths. The river is navigable in the province of Yun-nan; and it receives large volumes of water from the neighbouring mountains. In many parts the stream is deep; but in some places it is interrupted by shallows, rocks, and falls. Many flourishing cities are situated on its banks.

MEKRAN, or Mukran, a province of Beloochistan, bounded on the N. by Afghanistan and the province of Sarawan, E. by those of Jhalawan and Lus, S. by the Indian Ocean, and W. by Persia. It lies between 25. and 28. N. Lat., and between 58. and 66. E. Long.; and has a length of 500 miles, a breadth of 200, and an area of 100,000 square miles. The northern part of this district is mountainous, being traversed by two parallel ranges of mountains from E. to W. The most northern of these, which is the highest, is called the Wushutee Mountains; and between the two ridges lies a tract called Punjgoor, of very inferior elevation. The whole of this northern district bears the name of Kohistan, or highlands. The southern part of the province consists of a low, flat country, for the most part barren and destitute of vegetation. Mekran is separated from the adjoining province of Lus, on the E., by a range of hills called the Hara, running from N. to S. From the mountains down to the sea there stretch numerous water-courses, which are the beds of furious torrents in the rainy season, but at other times are quite dry. In this province there are two wet seasons,—one in February and March, when the wind is generally N.W.; and the other from June till August, when the country is visited by the S.W. monsoon. From March till October the weather is extremely warm, especially in the beginning of August, when the heat is so great as to confine the inhabitants to their houses. Along the coast there is hardly any winter at all, though in the highlands the weather from November to February is cool. The country being generally barren, the people are chiefly employed in pastoral pursuits. In some of the valleys a small quantity of corn is raised; in other parts vines are cultivated; and in the hottest places the date palm thrives remarkably, furnishing an important article of food. The trade of this province is inconsiderable, consisting in the exportation of wool, hides, dates, &c.; and the importation of cloth, iron, sugar, &c. Many of the inhabitants of the coast are employed in fishing, and live to a great extent on fish, as their ancestors did in the days of Alexander the Great. Mekran is in a state of great anarchy and confusion, being partly subject to Persia and partly to the Imam of Muscat; while the most powerful tribe, the Narroi Belooches, employ themselves in frequent and rapid forays, carrying off the inhabitants as well as their cattle. Through this province there are two practicable routes for an army from Persia to India,—one through the highlands, about 100 miles from the sea, and the other along the coast. The former, though more difficult of passage, and inaccessible for artillery, is better supplied with water and provisions than the latter, which was that taken by Alexander on his return from India. Pop. estimated at 200,000.

MELA, Pomponius, the earliest Roman writer on geography, flourished in the first century of the Christian era. From the fact that his surname was Mela, and that he was a Spaniard by birth, some have inferred that he was identical with L. Annæus Mela, the son of Seneca the rhetorician; but the only incidents in his life that are known as certain are gleaned from his work. In it we learn that he was born on the shore of the Bay of Algesiras, at a town which various lections have severally rendered *Tingentera* and *Cingentera*. His mention of the town of Cæsar Augusta, and his occasional allusions to Augustus, indicate that he must have lived at some period after that emperor. At the same time the fact that he speaks (iii. 6) of a mighty emperor triumphing on account of the conquest of Britain, renders it almost certain that he lived in the reign of Claudius, the first Roman potentate who can be said to have subdued that island.

The title generally given to the work of Mela is *De Situ Orbis libri iii.* In the introduction the author divides the northern, or known hemisphere, into three parts: Europe, bounded on the S. by the Mediterranean, and on the E. by the River Tanais (*Don*); Africa, bounded on the E. by the Nile, and on the N. by the Mediterranean; and Asia, the remaining portion. Then, commencing at the Pillars of Hercules, and passing along the southern shore of the Mediterranean, he describes Mauritania, Numidia, Africa Proper, Egypt, Arabia, Syria, Phœnicia, Cilicia, Pamphylia, Lycia, Caria, Ionia, Æolis, Bithynia, Paphlagonia, and the other districts along the coast of the Euxine. In the second book he begins at the Tanais (*Don*), and, coasting along the European shore, he describes Scythia, Thrace, Macedonia, Greece, the Peloponnesus, Epirus, Illyricum, Italy, Gallia Narbonensis, and the eastern coast of Spain. He then concludes this book by a description of the Mediterranean islands. The third book is occupied with an account of the western coast of Spain, the western coast of Gaul, the islands of the Northern Ocean, Germany, Sarmatia, the countries on the Caspian Sea, Carmania, Persia, Arabia, Ethiopia, and that part of Mauritania which borders on the Atlantic. In the composition of his work Mela has followed Eratosthenes, and other Greek geographers, with a closeness that sometimes prevents him from availing himself of the fuller and more accurate information of his own day. The text, chiefly on account of the abundance of proper names, is swarming with corruptions. Simplicity, conciseness, and perspicuity are the characteristics of the style. The best editions of Mela are those of Gronovius, 8vo, Leyden, 1728, and Tzschuckius, 8vo, Leipsic, 1807. There is an old English translation, entitled "The rare and singular Work of Pomponius Mela, that excellent and worthy cosmographer, of the situation of the World, most orderly prepared, and divided every parte by its selfe: with the Longitude and Latitude of everie Kingdome, Regent, Province, Rivers, &c., translated in Englyshe by Arthur Golding, Gent, 4to, London, 1590."

MELAMPUS, a famous physician and soothsayer in fabulous history, was the son of Amythæon. His mother is variously represented to have been Eidomene, Aglaia, and Rhodope. While living with his uncle Neleus, King of Pylos, in the Peloponnesus, he happened one day to fall asleep on the grass in front of his house. A brood of young serpents, which he had tamed, crawled upon his head, and began to lick his ears. Wakened by their touch, he started up, and discovered for the first time that he understood the chirping of the birds on the trees, and had thus acquired the means of interpreting the future. About the same time he had an interview with Apollo by the side of the Alpheus (*Rufia*), and was initiated by him into the mysteries of medicine. Melampus had gained great repute as a soothsayer, when his brother Bias fell violently in love with Pero, the daughter of King Neleus. The father, however, declared that no man could win the maiden's hand but he who should carry off the oxen of Iphiclus from Phylace. As that herd was guarded by a huge dog of noted ferocity, Bias did not dare to attempt the feat, but called in the aid of his soothsaying brother. Melampus accordingly proceeded to drive off the oxen, was caught, as he had foreseen, in the attempt, and was thrown into prison. During his confinement he contrived to make known his supernatural gifts, and was asked to prescribe a remedy by which Iphiclus might become a father. The prescription proved successful, and Melampus was presented with the coveted herd as a reward. He was next employed by Anaxagoras, King of Argos, to cure the women in his kingdom of an epidemic frenzy. In consideration of this service he was rewarded with one-third of the territory of Argos for himself, and another for his brother Bias. Instead of this story, however, some relate another. According to them, the three daughters of the Argive King Prœtus were the persons whom Melampus restored to sanity; and in return for his aid the physician received the hand of Iphianassa, or Iphianeira, the eldest of the princesses, and a third part of the territory of her father. By this wife he is said to have had four children,—Antiphates, Manto, Bias, and Pronoe. Melampus was reckoned by the ancients to have been the first prophet, and the first who practised the art of medicine. The medicinal herb μελαμπόδιον (*sneeze-wort*), acquired its name from having been first used by him. He received divine honours after death, and his temple was built at Ægosthena in Megaris. His descendants were a family of prophets.

MELANCTHON, Philip, or Melanthon, as he was accustomed to spell his name towards the close of his life, was born at Bretten, or Bretheim, a town of the Lower Palatinate, 16th Feb. 1497. His father, George Schwarzerde, or Schwarzerd, was a native of Heidelberg, an armourer of some celebrity in his trade, and a kinsman of the famous scholar Reuchlin. He was a man pious and affectionate, but at the same time stern and unflinching; and his calm, truthful nature seems to have been deepened into a grave and gloomy earnestness by the continued rankling of a sickness begun four years before his death, and by his friends attributed to an accidental draught of slow poison. On his deathbed he committed his son, then a boy of eleven years, to God's guidance, in prospect of "terrible tempests that were about to shake the world." Melancthon's mother, Barbara Reuter, was a daughter of a distinguished citizen of Bretten, who had for some years been mayor of the town. What her husband was from principle she was by instinct; and with her instinctive love of truth and charity there mingled an idealizing grace which seems to have bordered on superstition. She was the author of the popular housewifely rhyme, beginning

"Almosen geben armet nicht."[1]

She was passionately fond of young Philip, and remained a widow until the tie which bound them together was loosened, not without many misgivings on her part, by his marriage. On account of the armourer's incessant occupations, the early education of her favourite boy fell into her hands; but she was assisted by her father, and Reuchlin, her husband's kinsman, seems to have taken great interest in his progress. In approbation of Philip's boyish acquirements this devoted scholar sent him a present of two books, a Greek grammar and a Bible; and it is interesting to note that thus early his talents were turned into their destined channel, Greek literature and sacred learning. At a school at Pfortsheim, where George Simler was rector, Philip received his classical education. He lived, along with John Reuter, in the house of Reuchlin's sister, and was thus frequently brought into familiar intercourse with the rugged author of the *Epistolæ Obscurorum Virorum.* From Reuchlin, who had allowed himself to be dubbed "Capnio" (*Kapnos* being the Greek of *Rauch*, smoke), the young Schwarzerde (black earth) received the Grecized name of Melancthon, by which he is now universally known. In 1509 he was sent to the university of Heidelberg; and in 1512 he removed to Tübingen, where he acquired so great a reputation for scholarship as to deserve a high encomium from Erasmus, who predicted that himself and all the other lights of learning would soon be eclipsed by this stripling of eighteen. In the beginning of 1514 Melancthon received his doctorship in philosophy. He immediately began to give public lectures in rhetoric, and to expound Virgil and Terence and other authors. Of his inner history, as he was now approaching the crisis of his life, we can obtain only a passing glance. At a later period he tells us how he shuddered at the remembrance of his youthful image-worship; but we know that at this time he was a diligent student of the Scripture, and that as he carried the favourite Bible of Frobenius to the church, the monks, who thought every one a Jew who read Hebrew and every one a heretic who read Greek, did not fail to insinuate the heathenism of reading books of suspicious bulk within the sacred precincts.

He had been thus engaged for three years, when, on the nomination of Reuchlin, he was appointed by the elector of Saxony professor of Greek in the university of Wittemberg. "All Tübingen," says Simler, "lamented his departure;" but when he arrived at Wittemberg, after a journey which was a continued ovation, his slight figure, hesitant expression, and ungraceful gait, created an impression far from favourable. The facility and grace of his inaugural oration, however, quickly dispelled the fears of the professors; and Luther, who had shaken his head with the rest, was among the foremost to celebrate the learning and power of his youthful colleague. Melancthon, on his part, was not slow to appreciate the depth and warmth of Luther's character. A letter is extant, which seems to have been written about this time, in which Melancthon says, that "if he loved any man on earth with his whole heart, that man was Martin." And thus began the intimacy of two friends, destined, with their united strength, to roll the religious as well as the literary world back on its axis, but each leaving the impress of his own human weakness on the machinery which they framed to effect the revolution. "Luther," says D'Aubigne, "possessed warmth, vigour, and strength; Melancthon clearness, discretion, and mildness. Luther gave energy to Melancthon; Melancthon moderated Luther. They were like substances in a state of positive and negative electricity, which mutually act upon each other. If Luther had been without Melancthon, perhaps the torrent would have overflowed its banks. Melancthon, when Luther was taken from him by death, hesitated and gave way, even when he should not have yielded."

---

[1] Alms-giving beggareth not:
Church-going hindereth not:
To grease the car delayeth not:
Gain ill-gotten helpeth not:
God's book deceiveth not.
Müller's *Reliquien.*

Under the teaching of Melancthon, Wittemberg became the school of the nation. The scholastic methods of instruction were summarily abandoned; and in a *Discourse on Reforming the Studies of Youth*, which Melancthon gave in the first year of his professorship, the key-note was struck of a deeper earnestness in philology, and of a keener appreciation of truth, felt by minds of fearless truthfulness to be sacred, although buried in the classics of heathen antiquity. During that year his lectures were divided between Homer and the apostle Paul; and it is characteristic of the man that the same devout and reverent spirit guided his studies in both. In reading Homer he announced it as his aim, like Solomon, to seek Tyrian brass and gems for the adornment of God's temple. It is also significant of his tendency to purify where others would destroy, that, though at first carried away by Luther's denunciation of the Peripatetic philosophy, he quickly retracted his opinion, and sought to use the logic of the schools as a wholesome discipline in the service of theology. He was instrumental also, by his advent at Wittemberg, in stimulating and assisting Luther in the translation of the Bible, which was begun as early as 1517, but was progressing somewhat fitfully and slowly. All this happened within the bosom of the Church of Rome, with which his colleague and he were soon to be in open rupture.

Issuing from the patronage of Reuchlin, and deeply imbued with love for the Scriptures, Melancthon adopted without difficulty the principles of Wittemberg. In proof of his earnestness, he attended Luther and Carlstadt to the disputation of Leipsic. He took no public part in the debate, but, by his private suggestions to the combatants, he attracted the angry sarcasms of Eck, who was indignant that this grammarian, as he called him, should dare to interfere in the discussion. On its conclusion, Melancthon addressed an account of the debate in a letter to Œcolampadius; and so lightly did the passions of the time agitate his truthful nature, that this epistle contains no exaggerated eulogies of his own party, and even mentions the general admiration entertained towards Eck on account of his varied talents. Yet that vain polemic professed to be offended at this narrative, and affecting to appreciate the superior erudition of Luther, rejected with scorn the tribute offered by so unworthy a hand.

From this time forward Melancthon devoted himself almost exclusively to theology, and his history becomes so thoroughly interwoven with that of the Reformation, that only those points can be touched in which he stood aloof or alone among the band of Reformers. His life was chiefly spent in writing books, and visiting colleges and churches at the command of the elector. In 1520 he married Catharine Krapp, the daughter of a burgomaster of the town, and by her he had two sons and two daughters, who all survived him. She seems to have been of a very timid disposition. He admired her; was forced often to yield to her entreaties; but he never gave her half the love he gave to his books; and on the marriage-day, conscious of a kind of half-heartedness in the affair, he could not help saying she deserved a better husband. In 1521 he rendered what is his most valuable contribution to theological literature. His *Loci Communes Rerum Theologicarum* were a sort of summary of Christian doctrine, in which the truths asserted by Luther in his various compositions were reduced to a system, and thus more easily inculcated. The subjects of difference with the Romish church are distinctly stated with reference to scriptural proof, and without controversial argument—a method of persuasion better suited to moderate minds than the most eloquent appeals of impassioned reason. It was the opposite to the method of Luther; yet the latter was so sensible of its advantages, and so little bigoted to his own style, that he bestowed the strongest possible eulogy on the production of his friend: he ranked it incomparably above the writings of the fathers, and pronounced it to be the best book he had ever seen except the Bible. That in the heat of contending parties the exposition should be so calm, is a beautiful proof of the natural bent of Melancthon's mind to idealize his antagonists; but this necessity of his nature was all the more perilous for his peace and power, when error threw a veil over its practical extravagances, and became attractive only when impersonal. Thus, when Stubner and Cellarius, escaping from among the raving artizans of Zwickau, forced themselves on the peaceful society of Wittemberg, and gave utterance to their solemn impostures in his presence, the mind of Melancthon was perplexed and shaken. In pensive adoration of the doctrine of heavenly influences, which they put in the forefront of their teaching, he received and protected the men whose whole lives and utterances were a libel on the Spirit's agency. It is even said that he went so far as to advise his scholars to renounce the study of profane literature, and to confine their industry to the reading of the Bible and the practice of mechanical arts. Such power had the simple brightness of delusive doctrine to kindle reverence in his mind. It needed the keen practical instincts of Luther to detect the rent in the skirts of the idol's shining robe, and by a strong hand to expose the human folly and trickery concealed under the mask of mystery before which his companion trembled.

The share which Melancthon had in the transactions of the Diet of Augsburg has been already minutely given in this work under the Life of Luther. He fell under the *italitates* of his enemies at a time when a final blow required to be struck, but when his vision was hemmed in and his spirits oppressed by the dark clouds that overhung the national horizon. He had not the strong faith of Luther either in the warlike mission or the final triumph of truth; and it is no wonder that in such a battlefield the two friends should have parted company. That oppressive love of home, which was a peculiar feature in Melancthon's character, acting on a spirit tuned from boyhood to superstitious reverence, seems to have asserted its sway in this crisis of home-leaving from the Church of Rome; and in the entire absence of a sublime revenge against error and wrong, which is the birthright of the true reformer, there was no passion left in the mind of Melancthon to still the struggles of human tenderness, or break the chains of youthful awe. Besides, his catholic spirit, which had strong yearnings, although no prophetic glimpses, shrunk from the sad necessity of converting forts of defence into armed sanctuaries of solid stone, lest the building of the one temple of God should be delayed till not the tottering walls of Babylon, but the too narrow Jerusalem of the Reformed Church, should crumble into the dust. At all events, those who now inherit his hesitancy profess thus to interpret his spirit. The *Interim* of Augsburg, drawn up by Pflug, Sidonius, and Agricola, with the view of bridging over the chasm between the Roman Church and the Reformed, although it did not receive the approbation of Melancthon, is famous as having called forth the Adiaphoristic controversy, in which Melancthon propounded his views on the obligation of things indifferent to the personal salvation and purity of the believer. This *Interim adultero-Germanum*, as Calvin styled it, contained nearly the entire system of Romish theology; and Melancthon and the Philippists generally addressed themselves to the hopeless task of so modifying its statements as to accommodate them to the views of the Reformers. He was willing to tolerate both a popedom and a hierarchy, stripped, however, of divine right, and deprived of all power in matters of faith. He thought the church should allow seven sacraments, provided the name of sacrament was not given to those rites only of human origin. The relation of faith to works, and the doctrine of the sacraments, might, in his estimation, be veiled in a judicious obscurity of phrase. The contest assumed a new significance after the publication of the Leipsic *Interim* in 1548. In this deed the Philippists defined what those things were which they regarded as indifferent; and in which, for the sake of peace and unity, they thought they might be at liberty to obey the emperor. It must not, however, be forgotten, that from the views given in the *Loci Communes* as the expression of his own faith Melancthon never swerved; and that he regarded the surrender of more perfect for less perfect forms of truth as a painful sacrifice conscientiously rendered to the weakness of erring brethren.

By this time Luther had been two years dead. From their earliest intimacy he had delighted to call himself the forerunner of Philip, and had compared himself to a storm-wind ushering in the still small voice of his friend. The storm-wind, however, did not cease at Luther's death, and in the general confusion the calm voice of Melancthon was scarcely heard. The last years of his life were spent in fruitless conferences with the representatives of Rome on the one hand and the more distinguished Reformers on the other, in somewhat feeble replies to the fierce assaults of his enemies, and in the more pleasant duties of his professional office. How much his mild spirit was depressed by the contention of the times may be gathered from the tone of holy happiness which elevates his correspondence whenever, in his later years, he is called to celebrate the death of a dear friend. During the last three years of his life he suffered much from cold and intermittent fever. His wife died in the end of 1557; and the fatal year when he should be 63 years of age—a term to which he had looked forward with a mysterious dread as that beyond which his mortal existence could not possibly be prolonged—was fast approaching. In 1558 he calmly adjusted the desirability of living or dying; and in the one balance he found nothing but sin and the rage of theologians to be weighed against the light of God's face, the unveiling of the mysteries of providence on earth, and the full intelligence of Christ's nature in heaven. On the 12th April 1560 he delivered his last lecture; and his few moments of strength were spent in writing the *Chronicon*, a narrative of general history from the Creation to the Reformation. On the 19th April of that same year he breathed his last, having lived little more than two months beyond the period which he considered a fatal term. His body was laid in a leaden coffin close beside that of Martin Luther.

Melancthon's Life has been written by Camerarius, and from his biography we draw almost exclusively the details of his private and domestic history. There are, however, more recent sketches of his life and times by Karl Matthes; and by C. F. Ledderhose, Heid. 1847–8. In English there is a somewhat meagre biography by F. A. Cox, London, 1815; but the most enduring monument of his fame is the *Reformatorum Opera*, edited by Bretschneider, but still unfinished, the first 22 vols. of which do not exhaust the works of Melancthon.

MELBOURNE, the capital of the colony of Victoria in South-Eastern Australia, is situated on the River Yarra-Yarra, at the head of the large estuary of Port Phillip, in S. Lat. 37. 48., E. Long. 144. 58. The site was selected and occupied in the year 1835 by a small colonizing party from Van Diemen's Land. The town was officially recognised and designated two years afterwards by the government of New South Wales, to which colony Melbourne, together with the surrounding district, pertained until its formation into an independent colony in 1851 under the present name of Victoria. The capital of the future colony was named in honour of the English prime minister of the day, Lord Melbourne.

The rapid growth of Melbourne has given it an extension far beyond the limits of its original plan. The principal part of the town is still on the northern bank of the river, where it was first founded; but considerable divisions or wards have sprung up on the south side also, where South Melbourne, Sandridge, St Kilda, and the western part of South Yarra, are comprised within the city boundary. On the northern bank the site consists of two eminences, called respectively the Eastern and Western Hills, which, with the intervening hollow, have been overspread with streets and houses. The lower situations along the bank, and for a short distance up this hollow (now the main thoroughfare called Elizabeth Street), were until lately exposed to floods from the river; but the municipal improvements have now so considerably raised these exposed places as to cause little or no apprehension on this account for the future. The southern side of the river is flat and swampy, excepting the sandy margin upon the bay where Sandridge is built, and the rising ground where the other parts of Melbourne already spoken of are laid out. To the westward, on the N. side of the Yarra, is another flat called Batman's Swamp, having a salt lagune, without outlet, and a creek or chain of ponds entering it at the north, but without stream in its bed save on rare occurrences of heavy rains. So much surrounding low land is considered unfavourable to health; and the low parts of the town are decidedly so, especially in the present imperfectly drained condition of Melbourne. The original block of the town was laid out without open reserves, probably from the moderate anticipations of the future city. In the subsequent extension, however, this great defect has been remedied. Besides the Royal Park to the N.W., and the Police Paddock and other large spaces on the outskirts, there are the beautiful natural sites of the Carlton and Fitzroy Gardens, which are already being surrounded by the houses of the expanding capital.

The undulation of the site has occasioned some artificial levelling, although not to a great extent. The streets are mostly at right angles; and being of considerable length, straight, and of ample width, they have a good appearance. All the principal lines are well finished, being macadamized in the middle, and drained, kerbed, and to a great extent flagged, on either side. In the original plan there were alternate lanes or narrow streets, which had been intended to serve as back entrances to allotments extending from the main streets. As the town increased, however, and the lands became very valuable, the original allotments were subdivided to a degree far beyond what had been anticipated, so that those lanes soon became independent streets, and among the busiest hives of population and trade. They are thus an unhealthy feature of the older town; and the mistake has not been repeated with the newer plans.

The climate of Melbourne in its mean results is cooler, as usual in the Southern Hemisphere, than that of the same latitude in the N., but it is subject to very frequent changes, particularly during the summer season. The mean temperature of January last (midsummer), for example, was 66°·4. The highest indicated temperature was 101°·1, the lowest 48°; while the mean daily range of the month was so considerable as 19°·4. It is not, therefore, a climate suited to invalids, as is often supposed. It possesses, however, an agreeableness of character, arising from the great proportion of fair and sunny weather, which is especially noticeable to the British emigrant. Another mistake, still more common, attributes to Australian colonies a very diminished supply of rain as compared with European countries. On this subject the following results are interesting, as they compare the rain-fall at Melbourne with that at London :—At Melbourne the annual mean of five years (1847-51) gave 32·63 inches; while at London the mean of twenty years, ending in 1846, gave only 24·04 inches. The seasons of greatest rain in each are somewhat different. The wettest months at Melbourne were those between April and November inclusive, when the monthly mean was 3·4 inches; while the driest were between December and March, the monthly average being only 1·3 inch. Thus the most rain occurred from the last half of autumn to the beginning of summer; while in London, it would appear, the rain falls proportionably most from midsummer to the beginning of winter (June to November). This is almost an exact reversal; but as the opposites in the antipodean seasons have been allowed for, it follows, that both in London and at its antipodes the greatest proportions of rain are occurring during about the same time.

The commerce of Melbourne has already attained to a scale that constitutes it, so far as regards that test, the principal port of the British colonial dominions and of the Southern Hemisphere. This great and sudden development is due to the Australian gold discoveries that took place in 1851. Although the first discoveries were made in New South Wales, yet Victoria, where the gold was soon after found, has ever since yielded by far the larger proportion; and as nearly all the auriferous wealth flows through Melbourne, that place has thus acquired its surpassing importance.

The following figures represent the import and export commerce of the port of Melbourne for the last two years (1855 and 1856) according to the declared value at the customs :—

	1855.	1856.
Imports	L.10,232,279	L.13,240,751
Exports	12,706,849	14,363,250

Nearly the whole external commerce of the colony has been gradually concentrating in Melbourne. For the year 1855 the total amounts for the colony were,—imports, L.11,568,904; exports, L.13,469,194; from which we observe that Melbourne possesses nearly eight-ninths of the import and sixteen-seventeenths of the export commerce. The export of gold is in the proportion of five-sixths of the whole amount of exports.

The great and yearly expanding importance of Melbourne as a seaport demands for that part of our subject a short notice. The city is 8 miles by river course from the mouth of the Yarra, and thence to the Heads of Port Phillip is 35 miles. These Heads are but 2 miles apart; and through this strait, so narrow as compared with the expanse of Port Phillip, the ebb and flow of the outer ocean sweeps with a strong current of 5 or 6 miles an hour, rendered more remarkable by the eddying and jumbling of the water caused by the great inequality of depth in the channel. Ships sailing inwards are in a few minutes transported from the stormiest to the calmest waters. Each in-flowing tide is charged more or less with sand, sustained while the waters are in motion, but deposited when they have come to rest within the bay. Thus has arisen a system of sandbanks extending 12 miles inwards, and navigable by several channels, the deepest of which, called the South Channel, takes a circuit by the S. and E. of the bay. As the entrance is dangerous, particularly at night, pilots cruise about outside. The danger, however, is now much diminished since a second light has been added to Shortland's Bluff, so as to afford a safe entrance by keeping the two in line.

The anchorage is at Hobson's Bay, the upper part of Port Phillip, where the larger vessels were discharged by means of lighters until within the last two years, when the Melbourne and Hobson's Bay Railway began to expedite this tedious process. The railway from Williamstown, now nearly completed, will be a further improvement; and although considerably longer, it has the advantage of a better sheltered jetty than the other. Extensive wharf accommodation has been recently made at Melbourne to accommodate the fleet of the smaller shipping and the lighters. The authorities, in regard to harbour improvement policy, have been for some time undecided between deepening the present circuitous river-course and opening a new and straight cut to the bay; the first being 8 miles, while the other would be only about 1¾ mile. Opinion now inclines to the first. The river has two bars or shallows,—one at the mouth, the other half-way to Melbourne; and neither has more than nine feet of water at usual flood-tides. Besides these, however, other places, although not so shallow, require to be deepened. Neither scheme can be carried out without heavy expense; still the object to be attained is greatly more important than the consideration of its cost. A patent slip on a large scale is now being erected at Williamstown. The rise and fall of tide in the bay has usually a range of only three feet. Persons interested in shipping and merchandise should be careful, in bills of trading, of the use of the words "Port of Melbourne," which, although intended to mean Melbourne itself, is now usually held to be the anchorage off Williamstown, unless the vessel is destined for or is able to proceed up to "Melbourne Wharf."

Melbourne is the seat of a municipality, which was conferred in the year 1843. The mayor and aldermen are elected by the council. The following is the valuation of the city, taken for the purpose of levying the rate, for the six years ending 1857 :—

1852	L.174,723
1853	638,824
1854	1,553,965
1855	1,077,725
1856	726,807
1857	911,414

The valuation for each year is taken towards the end of the year preceding. We here observe the great rise in value caused by the gold discoveries. Not less striking is the reaction after 1854, when the colonists had gone too great a length. The year 1856 gives less than half the value for 1854, notwithstanding that some extension and improvement had been effected intermediately. As the colony is again actively progressing, the value for 1857 shows a large advance on that of the preceding year. The number of houses for 1857 is given at 10,334, affording the unparalleled average of nearly L.90 of yearly value for each house.

The municipal revenues are considerable. In 1854 they amounted to L.69,938 in gross total, and in 1856 to L.71,717, which last amount comprised L.48,000 of city rate, L.10,000 of lighting rate, and L.8000 of market dues. The expense of salaries for 1856 was L.12,954. In 1854 L.500,000 was borrowed by the corporation under the sanction and with the guarantee of the colonial government. With so effective an aid the town was greatly improved in its streets. Already nearly a million sterling may be computed to have been spent in such improvements.

Melbourne is the seat of the colonial government, which is now, since the recent concession of political freedom, administered on the constitutional plan of that of England. There are two houses of parliament, both elected by the people; while the governor is nominated by the crown. The press is an active agent, and issues three large daily papers in Melbourne, besides various others at longer intervals.

Melbourne already possesses many public institutions of a charitable or useful description. The hospital was begun in 1846; and in 1856 administered to 1725 in-door and 3393 out-door patients. There is also a benevolent and a lunatic asylum, a mechanics' institution and public library, and latterly a spacious and costly university, which as yet, however has not been adequately supplied with pupils. The Parliament-House, which is still unfinished, will be a very large and handsome structure.

The costliness of everything, and the rush and bustle of life and business during the first years of the gold-digging, caused the erection of many poor and temporary structures throughout the town. Many grotesque-looking edifices of wood and iron had been rapidly put up, which contributed little by way of ornament, and still less of comfort under the extremes of the climate. An entire suburb of tents on the southern side of the river acquired the significant name of Canvastown; but it has now happily quite disappeared, and with it much misery and mortality. The iron and timber buildings are gradually being displaced by a better kind of edifice as their sites get more valuable. There are now many handsome shops, and a considerable profusion of plate-glass, which begins to appear in the windows of private residences as well as of numerous shops and warehouses. Many houses of timber or iron still remain; but, with few exceptions, the custom is now to build of brick or stone, particularly of the former, as bricks are now largely made in the country. The various churches, which are chiefly collected upon the Eastern Hill, exhibit amongst them some large and costly edifices. The banking companies, too, have erected handsome places of business; and many substantial warehouses of the merchants are scattered over the town. The river is crossed by a bridge of unusually large span. The chief thoroughfares are crowded with traffic, with foot-passengers and omnibuses, to an extent not inferior to that exhibited by the larger and most stirring of the British towns.

Melbourne boasts of a large "Theatre-Royal," nearly equal in its accommodation to the largest London houses. There are two smaller theatres, and a spacious "Astley's." The last is a wooden fabric, and being capable of containing 4000 persons, it is much used for the political and other "mass meetings" of the colonists. In the suburbs are "Cremorne Gardens," where fireworks, Sebastopol sieges, and other attractions are nightly exhibited. The annual races last for three days, and are always so absorbing as almost to cause a general holiday-making. Cricket, too, is a favourite pastime both in Melbourne and throughout the colony.

In front of the town-hall and adjacent police-office is a considerable stand of cabs. There are regular daily coaches to the interior towns that are rising rapidly upon or near to the different gold-fields; and a growing fleet of steamers maintains regular communications with neighbouring ports and colonies,—namely, daily to Geelong, and at wider intervals to Alberton, Sydney, Portland, Adelaide, Launceston, and Hobart Town. Railway travelling is as yet confined to the two miles of the Melbourne and Hobson's Bay line, and a small part of the Geelong and Melbourne line next the former town; but it is expected that the present year (1857) will witness the opening of the entire way, together with the branch of the Hobson's Bay line to St Kilda, and the line to Williamstown. The great lines to the gold-fields are as yet scarcely commenced.

Among the more recent improvements in the city connected with the sanitary and general wellbeing, we may notice the erection of an elegant and substantial market-place in the Custom-House Square; and in the same locality a savings-bank and a fine exchange edifice for the use of the commercial interests, and a place of meeting for the Chamber of Commerce. In January 1856 Melbourne was lighted with gas. At a latter period of the same year a supply of water was introduced throughout the town, raised from the river by pumping machinery. By this arrangement, besides the supply to the dwellings, there is a regular watering of the streets; while the risk from fire is greatly diminished. This supply, however, is only temporary, pending the completion of the gigantic works connected with the Yan Yean reservoir, near the head of the River Plenty, about 18 miles to the N.E. of the town. Immediately following this completion will come the much-wanted drainage and sewerage, upon which the health of the population of Melbourne so greatly depends.

The increase of the population of Melbourne has been as remarkable as that of its commerce. The census of 1841 gives it 4440; that of 1846 a little short of 10,000. In 1851, just prior to the gold discoveries, it had attained to 23,000; but in 1854 the numbers were 53,235, while the suburbs contained 23,330,—making a total of 76,565.

A census taken on 29th March last (1857), but the results of which have not yet been made public, will probably give to Melbourne about 70,000 within the city boundaries, besides 30,000 in the suburbs, making a total of 100,000 souls.

(W. W—H.)

MELCHISEDEC, (מלכי־צדק, *rex justitiæ*), the name of an individual who occupies an important place amongst the characters which appear in the Old Testament history, as typical of Christ. Very little, however, is said in Scripture regarding him personally; his name occurs only twice in the Old Testament (in Gen. xiv. 18, and in Psalm cx. 4); and the reference to him in the New (in Heb. vii. 20, and vii. 1) has respect only to his typical character. His name is mentioned for the first time in the sacred history on the occasion of the return of Abraham from the defeat of the four kings or sheikhs who had invaded the district of Sodom, and carried captive his nephew Lot. In the valley of Shaveh, or "The King's Dale," probably the same valley as that mentioned under the same name in 2 Samuel xviii. 18, the victor was met by Melchisedec, who is described as "the King of Salem," and who, with the generous readiness of eastern hospitality, set before him and his troop "bread and wine,"—that is, a plentiful repast.[1] Whether the Salem here mentioned is the same as that mentioned in Psalm lxxvi. 2, and which is plainly Jerusalem; or is, as Jerome suggests, a place near Scythopolis, and which he identifies also with the Salem near to which John the Baptist baptized, remains still a matter of dispute among scholars. The majority of eminent names is in favour of the former opinion; but Bochart, Rosenmüller, and others, have decided for the latter.[1] In addition to his royal dignity he sustained also the sacerdotal office: "he was priest of the Most High God;" and in this capacity he pronounced a benediction on Abraham. In return for his kindness, and especially from reverence to his priestly office, the patriarch gave him a tithe of all the spoil he had taken in that expedition, from which he was then returning.

---

[1] Patrick, *in loc.* Josephus, *Antiq.* i. 9.

This is the sum of what Moses records respecting Melchisedec; and the only addition that can be made to the recital from the other passages above referred to is, that his priesthood was not derived from hereditary descent, but had been conferred on him by the immediate appointment of God.[2] Meagre, however, as this account is, there is something in the character and position of the individual to whom it refers of so singular a nature, as at once to excite curiosity, and stimulate further investigation. That in a land inhabited by the accursed race of Canaan, and at a time when the knowledge of the true God was confined apparently to Abraham and his dependents,[3] an individual descended from that race should have been found uniting in himself the two offices of priest and king, worshipping the true God of heaven and of earth,[4] and so eminent in dignity and piety that his blessing was gratefully received by Abraham, and the divinity of his priesthood acknowledged on the part of the patriarch by an offering to him of tithes, are circumstances which cannot fail to excite the surprise of every reader of the sacred narrative. It is natural for him to ask—Who or what was this extraordinary character? From what race did he spring? Whence did he derive his knowledge of the true God? Or how came he to be "a king of righteousness," and "a king of peace," as well as a priest of God, in the land of Canaan? To these questions the narrative of Moses furnishes no reply; and what is said of him in other parts of Scripture[5] only tends to heighten our curiosity, by the elevated rank which is there assigned to him as a type of the Messiah. Our only resource in such a case is probable conjecture, and to this it is not surprising that expositors of the Scriptures, both in ancient and modern times, should have had recourse; nor is it to be wondered at that the opinions which they have advocated on the subject have been both numerous and discordant. To recapitulate the whole of these would only be to occupy space which might be far more usefully filled; we shall therefore confine ourselves to a statement of one or two of the most prominent, with a brief view of the arguments by which they have been enforced.

1. By the Jewish expositors generally Melchisedec is said to have been Shem, the son of Noah, and this, as we learn from Epiphanius (*Hæres.* lv., p. 205), was also the opinion entertained by the Samaritans. It has likewise been held by a few Christian interpreters, amongst whom is Luther. The passages from Jewish writers advocating it have been carefully collected by Bochart (*Phaleg.*, lib. ii., c. 1), who has also very satisfactorily shown its absurdity. Apart from the decisive evidence furnished against it by the statement of Paul, that Melchisedec was one whose descent could not be identified with that of the Levites (*μὴ γενεαλογούμενος ἐξ ἀυτων*, Heb. vii. 5),—a statement which is not true of Shem, who was in the regular line of Levi's progenitors,—it seems highly unreasonable that Moses, who often mentions Shem, should here introduce him under another name, without giving any explanation as to the person really intended; nor is it easily conceivable that Abraham should have been described as "sojourning in a *strange* country," if he had been in the immediate vicinity of his ancestor Shem. The Jews, moreover, are not unanimous in this opinion, for Josephus tells us that Melchisedec was a prince of the Canaanites;[6] and in one place of the rabbinical book Sohar[7] he is spoken of as a *type of the King of true peace.*

2. Augustin and Theodoret severally inform us of a class of heretics in the early church, who received the name of Melchisedechians, from their holding the opinion that Melchisedec was a mighty divine power (*dei virtutem, μεγάλην τινα καὶ θείαν δυνάμιν*), superior to Christ, and the model after which Christ was formed. The founder of this sect was one Theodotus, an usurer, who seems to have flourished about the year 174.[8] An advance upon this opinion was made by Hierax, who, as we learn from Epiphanius, identified this divine power with the Holy Spirit (*Hær.* lv., p. 304). The sect seems to have commanded little attention, and their opinion is worthy of notice only as forming one of the heresies of the early church.

3. By some of the fathers, and not a few of the more modern expositors, Melchisedec has been regarded as the *Logos* or second person of the Trinity, who appeared to Abraham, not incarnate, but only, as Epiphanius expresses it, *ἐν ἰδέᾳ ἀνθρώπου*, in the model of man. In defence of this opinion, its advocates adduce, *first*, the acknowledged fact that such appearances were vouchsafed to the patriarchs, as in the case of Abraham, when "the *Lord*" communed with him respecting the destruction of Sodom, and of Jacob, when he wrestled with the angel, and saw "*God* face to face;" *secondly*, the evident mystery attached in Scripture to the person and character of Melchisedec, "of whom," says Paul, "we have many things to say and hard to be uttered;"[9] *thirdly*, the assertion of the same apostle, that Melchisedec was not mortal, implied in his declaration, that whilst other men who receive tithes die, "it is witnessed of him that he liveth;"[10] *fourthly*, the strong and unqualified terms in which the unearthly origin of the "order" of his priesthood, and its perpetual duration, are spoken of by the same apostle, as well as by the psalmist;"[11] *fifthly*, the language of Paul in regard to the mysterious existence of Melchisedec, as "without father, without mother, without descent, having neither beginning of days nor end of life,"—language strikingly applicable to Christ,—"whose goings forth have been of old from everlasting," but hardly to be understood of a mere man; and, *finally*, the circumstance of Melchisedec's receiving tithes as a free-will offering from Abraham, a homage which was rendered by the pious to none but the Almighty. On the side of this theory are ranked some eminent names both in the early and in the modern church. It is enough to mention those of Ambrose, Damianus, Moulin, Cunæus, Outrein, Hottinger, Starke, Gaillard, Ridgley, Hunter, Henry, and Brown. An able defence of this opinion has appeared in a work entitled *Melchizedek*, by the author of *Balaam*, *Elijah*, &c., London, 1834, the production, we believe, of a lady. The opinion is very fully examined and refuted in vol. ii. of Wardlaw's *Systematic Theology*, p. 315.

4. By far the most common opinion is, that Melchisedec was a righteous and powerful king, a worshipper and priest of the Most High God, in the land of Canaan, and a type of Jesus Christ. In support of this opinion it is contended, *first*, that the mysterious character attributed to Melchisedec in Scripture is nothing more than belongs to all the prophetical types; and that when Paul says he has many things to say respecting him which are hard to be uttered,

he only means, that owing to the carnality of those to whom he was writing, the revelation which he was about to give of the *spiritual* character of Melchisedec as a type of Christ, would not be easily apprehended;[1] *secondly*, that his being described as ἀπατωρ και ἀμήτωρ, may mean that he was the first of his family who sustained the royal and sacerdotal dignity; or, if it be understood naturally, it implies nothing more than that his descent was not matter of record, in the same way as Sarah is called ἀμήτωρ by Philo, because her mother's name is not known, or as Servius Tullius is said by Livy to have been born *patre nullo, matre serva*, because only his mother's name (Cornicula) was matter of history; *thirdly*, that what is said of his being "without beginning of days or end of life," refers merely to our ignorance of the time and manner of his birth and of his death, which are purposely left unrecorded, in order that he might serve as a type of Christ, "who ever liveth;" *fourthly*, that the expression, "of whom it is testified that he liveth," is only a concise repetition of the preceding statement;[2] *fifthly*, that in all the *certain* instances of Divine appearances recorded in the Old Testament, the fact of the Deity's being present is made apparent in the narrative itself; and that this not being done in the case of Melchisedec renders it unjustifiable, without express authority from some other part of Scripture, to suppose that he was such an appearance; *sixthly*, that had Melchisedec been himself the Son of God, the apostle would not have said that he was "made like (ἀφωμοιωμένος, *assimilatus, likened to, compared to*) the Son of God," for this would have been to compare him with himself; *seventhly*, that no sufficient reason is apparent from the narrative for so extraordinary a revelation as that of the second person of the Trinity in human shape, nor does any end worthy of such means seem to have been answered by the interview; and, *finally*, that Abraham's offering of a tithe of the spoil might with great propriety be presented to Melchisedec, though only a man, as an act of homage, not to himself, but to that God whose priest he was, and in whose name he had blessed the patriarch. This view of the subject has been adopted by a majority of the fathers, as well as of modern divines. It has been strenuously defended by Dr Owen, in his work on the Hebrews, where he denounces the opposite opinion as a series of "groundless fables" and "woful mistakes;" and has received the suffrages of the greater part of those who have commented upon that epistle, amongst whom may be mentioned the names of Calvin, Cameron, Scott, Blomfield, Stuart, Kuinoel, Tholuck, and Ebrard. It may be regarded as the *common* opinion of the orthodox church.

According to this opinion, the reasoning of St Paul, in the passage referred to, goes to establish an analogy between Melchisedec and Christ, in respect of the following points:—*First*, of *name* and *designation*, both being denominated "king of righteousness," and "king of peace;" *secondly*, of *obscurity of descent*, both being without beginning of days or end of life,—the one because his genealogy is not recorded, the other, because with regard to him this was literally true; *thirdly*, of *the homage rendered to both by their receiving tithes as a free-will offering*, the one in the name of the God whom he served, the other in his own name; *fourthly*, of *the peculiar character of the office they sustained*, neither having had either predecessors or successors, the one because God arranged it so, the other because it was of necessity so; and, *fifthly*, of *the superiority of both to the priests under the law*, the one having blessed, as a superior, Abraham, the father of Levi, the other having abolished the whole economy of the Levitical priesthood by the sacrifice of himself.[3]

(W. L. A.)

MELCHTHAL, Arnold of, one of the restorers of Swiss freedom, was the son of a wealthy proprietor, and was born in the canton of Unterwalden, in the latter half of the thirteenth century. His real name was Winckelried, but he was universally known by the name of his residence. At this time Switzerland groaned beneath the oppression of Albert of Austria. One day the valet of Handenberg, an Austrian bailiff, seized upon a yoke of oxen belonging to Melchthal's father, and, as he was driving them away, remarked, that peasants, if they wanted to eat bread, should hold the plough themselves. Stung by such insolent rapacity, young Melchthal struck the menial to the ground, and fled from punishment to his native fastnesses. The information that his father's eyes had been put out by the revengeful tyrant, served only to strengthen his determination to free his country. He received into his confidence Fürst, of the canton of Uri, and Stauffacher, of the canton of Schwytz. On a night of November 1307 the three patriots met on the solitary banks of the Lake of Lucerne, and there they took an oath to advocate in their several cantons the cause of freedom, and to drown every revengeful feeling and every personal motive in the one prevailing desire for the liberty of their country. The bold feats of William Tell, in the same month, accelerated the execution of their plans, and raised to arms the natives of Uri, Schwytz, and Unterwalden. Arnold of Melchthal, along with his compatriots Fürst and Stauffacher, led the mountaineers on to victory. On the battlefield of Sempach he is said to have attempted, single-handed, to break an impregnable line of Austrian lances, and to have fallen with "a sheaf of spears" sticking in his breast.

MELDRUM, Old, a burgh of barony and a parish of Scotland, Aberdeenshire, 18 miles N.N.W. of Aberdeen. The town contains an Established, a Free, a United Presbyterian, and an Episcopal church; two schools, and a savings-bank. The inhabitants are employed in agriculture, weaving, brewing, distilling, &c. Market-day, Saturday. Pop. (1851) of burgh, 1579.

MELEAGER, a Greek epigrammatist, and the collector of the first Anthologia that is known, was the son of Eucrates, and flourished at Gadara in Palestine about 60 B.C. His collection was made from the works of forty-six authors, and was entitled Στέφανος, *The Garland*. The authors were Anytus, Myro, Sappho, Melanippides, Simonides, Nossis, Rhianus, Erinna, Alcæus, Samillo, Leonidas, Mnasalces, Pamphilus, Pancrates, Tymnes, Nicias, Euphemus, Damagetus, Callimachus, Euphorion, Hegisippus, Perseus, Diotimus, Menecrates, Nicænetes, Phaennus, Simmias, Parthenis, Bacchylides, Anacreon, Anthemius, Archilochus, Alexander Œtolus, Polycletus, Polystratus, Antipater, Posidippus, Hedyles, Sicelides, Plato, Aratus, Cheremon, Phedimus, Antagoras, Theodorides, and Phanias. This collection has disappeared, but we possess 131 epigrams, which are said to have been the production of this poet. They are written principally on amorous subjects, and are remarkable for the elegance of their versification. The best editions of Meleager are that of Manso (Jena 1789), of Meinecke (Lips. 1789), and at Græfe (Lips 1811). See Fabricius, *Biblioth. Græca*, tom. iv.; *Prolegomena* to the

---

[1] The word he uses is δυσερμήνευτος, which the Vulgate renders *ininterpretabilis*.

[2] Wardlaw rejects this with the remark, "This will not do," and adopts in preference the interpretation which refers "he liveth" to Christ; an interpretation, again, which Ebrard says "is mere nonsense." We beg to dissent from both decisions. That the interpretation which Wardlaw rejects "*will* do" Ebrard shows; and that the view which Ebrard denounces is not "nonsense" is sufficiently proved by Wardlaw.

MELEDA (anciently *Melita*), an island of the Adriatic, off the coast of Dalmatia, from which it is about 3 miles distant, and 17 W.N.W. of Ragusa. Length 23 miles; breadth 4 miles. The island contains lofty mountains of a bare and dry aspect; and there are also some fertile but not well cultivated valleys, producing corn, wine, vegetables, and fruits. Sheep, goats, bees, and silk-worms are reared in large numbers and with considerable care. The coast is irregular, and contains numerous harbours, one of which, Palazzo, on the N. of the island, is reckoned the best in Dalmatia. Meleda has been supposed by some to be the scene of the shipwreck of St Paul; but this opinion is now very generally abandoned in favour of the modern Malta. Pop. 900.

MELENDEZ VALDES, Juan, a distinguished poet of Spain, was born at La Ribera del Fresno in Estremadura, on the 11th of March 1754. After studying philosophy at Madrid he went to the university of Salamanca at the age of eighteen, where he pursued the study of law, and made the acquaintance of some of the most eminent literary men of the time in Spain. His earlier efforts at versification were in imitation of Lobo, who had still many admirers, but who belonged to a bad school. The elder Moratin, however, who was thoroughly opposed to the vicious poetical taste of his time, was beginning to leave traces of his influence on the mind of the young follower of Lobo, when a fortunate accident brought Cadahalso to Salamanca. The sympathetic discernment of this eminent poet and soldier soon detected the latent genius of Melendez, and induced him to take him to his house, where he spent great pains in disclosing to the young poet the beauties of the elder literature of Spain, and of the cultivated nations of Europe. It was through Cadahalso that Melendez first became acquainted with the literature of England, which subsequently exerted so marked an influence on his poetic development. He was accustomed to remark in later days, that it was John Locke who first taught him to reason, and that four lines of Pope's *Essay on Man* were superior to all that poet ever wrote. The devoted friendship of Cadahalso met, accordingly, with an ample reward in the great success of his pupil; and it was afterwards said, with as much truthfulness as point, that "among all the works of Cadahalso, the best was Melendez." But the most commanding mind of the time was that of Jovellanos, whose friendship Melendez afterwards formed through Gonzales. This new relationship at once exercised a decided and salutary influence over him. In 1780 he obtained the prize of the Spanish Academy for the best eclogue, although he had to contend with a formidable rival in Yriarte, his senior in years, and in court favour. The performance of the latter was written in the declamatory style of some of the older and weaker Spanish pastorals; while the *Batilo* of the former was fresh from the fields, and, as one of the adjudicators said, "seemed absolutely to smell of their wild flowers." Melendez, on going to Madrid the following year, was received with much cordiality by Jovellanos, and received new honours from the academy of San Fernando for a Pindaric Ode *On the Glory of the Arts.* He was shortly after appointed professor of the humanities or philology at Salamanca, which enabled him to return to his favourite haunts on the banks of the Tórmes. In 1784 he was induced by Jovellanos to compete for the prize offered by the city of Madrid for a dramatic performance. His comedy of *The Wedding of Camacho* (*Las Bodas de Camacho*) secured the vote of the judges, but was received coldly by the public, and soon fell into neglect. The talent of Melendez was not dramatic; and he made an attempt the following year to retrieve his fallen fortunes by presenting the public with a volume of lyrics and pastorals; a species of composition for which his genius was peculiarly adapted. His success was extraordinary. The genuine simplicity and tenderness of those pieces, their elegant versification and light gracefulness, their rich, truthful descriptions of natural scenery,—all combined to communicate to them a fascination such as had not been known in Spain since the disappearance of the eminent names of the sixteenth and seventeenth centuries. Indeed, so subtle and exquisite is the grace of those charming poems, that it is precisely the sort of beauty which is sure to be lost in being strained through any translation. Three counterfeit editions of this small volume appeared in 1785, and were sold off as fast as they were printed.

In an unfortunate hour Melendez, the darling of the court, resolved to leave his happy retirement, and solicit a place under the government. In 1789 he was made a judge; and in 1791 was elevated to a position of honour in the chancery of Valladolid: this new duty did not, however, estrange him from the muse. He published in 1797 a new and greatly enlarged edition of his works, which he dedicated to the Prince of the Peace, with whose misgovernment the poet was now too closely connected, from the necessities of his political position. This new effort did not add greatly to his fame. The influence of English and German literature was more obvious than salutary. In his *Ode to Winter* he imitates Thomson, and *The Fall of Lucifer* is a faint echo of Milton. The fervid glow of the rare old Castilian verse was not consistent with the laboured moralizings and dreary metaphysical discussions which Melendez, after the manner of Jovellanos, now packed into his lines. The prince was flattered by the dedication, however, and attached the poet to the court at Madrid, where Jovellanos was a minister of state. But the next year saw these eminent men in exile; and it was not till 1802 that Melendez, by the mitigation of his persecution, was permitted to return to the scene of his early fame at Salamanca. After six years came the revolution of Aranjuez, when he hastened to Madrid only to be in time to witness the ascendancy of the French power, to which he, in a moment of infatuation, gave in his adherence. On being sent as a commissioner to Oviedo, he was led out by the infuriated populace to be shot; and on another occasion his house was sacked, and his valuable library destroyed, by the very party whose interests he served. Melendez fled; and after dragging out four miserable years in exile in the south of France, he died at Montpellier on the 24th of May 1817.

Melendez solaced himself during the heavy hours of exile by preparing a complete edition of his works, with numerous corrections and additions, which was published, with a Life of the author, by Quintana, at Madrid, in 4 vols. 8vo. His anacreontics still retain their fame; and he is universally regarded as the greatest poet Spain had known for an entire century. (See Ticknor's *History of Spanish Literature,* vol. iii.)

MELETIUS, Bishop of Antioch, a famous ecclesiastic, was born about the beginning of the fourth century at Melitene (*Malatiah*) in Armenia Minor. His first important pastorate, the bishopric of Sebaste, was rendered so intolerable, through the stubborn conduct of the people, that he resigned it shortly after his appointment, and retired to Berœa (*Aleppo*) in Syria. At this time the Arian controversy was engrossing the minds of the Christians of the East, and was fast extinguishing all deep and true piety. The pastors fed their flocks with nothing but the dry formulæ of doctrine and the vehement ebullitions of sectarian zeal. But Meletius, keeping ever in view the design of the priesthood, endeavoured, both by his ministrations in the pulpit and by his walk in private life, to recommend to his people the essential doctrines of the gospel. He thus undesignedly secured the respect of both the factions in the church, and was elevated by universal consent to the

Meletius.

see of Antioch in 360. The public conduct of Meletius now became more decided. He saw that in his influential position he was bound to act a part in a dispute that was interrupting the concord of the Christian world. Accordingly, in his inaugural discourse in 361, he expressed, in subdued yet unmistakeable terms, his sympathy with the orthodox party. This confession awakened the slumbering spirit of controversy in the church of Antioch. The Arians forthwith charged Meletius with Sabellianism and other crimes, and in the course of a month he was banished to his native Melitene by command of the Emperor Constantius. At the same time the orthodox party in the church of Antioch seceded from the communion of the Arians. On the accession of the Emperor Julian in 362 Meletius was recalled from exile. He now bent all his energies to effect a union between the Eustathians and the orthodox section that had separated from the Arians at his own deposition; but the former party, although they had seceded from the church of Antioch on the same grounds as the latter, could not sympathize with the liberal-minded Meletius, and declared that they would recognise no bishop who had been consecrated by Arians. The Council of Alexandria interfered to settle this dissension, and sent Lucifer of Cagliari to Antioch. But that hot-headed bishop was the worst mediator that could have been found; and he immediately destroyed all hope of a reconciliation, by ordaining Paulinus bishop of the Eustathians. Soon after the accession of Valens in 364 Meletius was again banished. He was recalled, along with other exiles, by an edict of Gratian in 378; and not long afterwards he was reinstated in his bishopric. His exertions were again turned towards a union with the Eustathians, but were frustrated by the unrelenting prejudice of their bishop, Paulinus. Meletius died at an advanced age while attending the Council of Constantinople in 381. His body was conveyed to Antioch, and buried with great honour beside the tomb of the martyr Babylas. Gregory of Nyssa pronounced his funeral oration. A part of the inaugural sermon of Meletius at Antioch is printed in the 5th vol. of Galland's *Bibliotheca Patrum*.

Meletius, the founder of the sect of the Meletians, was Bishop of Lycopolis in Thebais in the beginning of the fourth century. During the bitter persecutions that assailed the Christians in the reigns of Diocletian and Maximian, he and his superior, Peter, Archbishop of Alexandria, were fellow-prisoners for the faith. Torture and hardship meanwhile were wringing from many an abjuration of their religion. Some of these backsliders, however, could not enjoy in peace the freedom they had so ignominiously bought, and, repairing to the two imprisoned bishops, they desired to be reconciled to the church. Peter at once declared that their request ought to be granted after they had undergone a suitable penance; but Meletius, occupying as a metropolitan a rank second only to the archbishop, ventured to oppose this decision, and refused to have any intercourse with traitors to the faith until the close of the persecution. The question was then submitted to the vote of the imprisoned Christians, and was settled by a majority agreeing with the opinion of Meletius. The schism, thus begun in a dungeon, was carried by the prisoners to the mines of Phœnon in Arabia Petræa, and rose into prominence when Meletius was finally liberated. The headstrong bishop then set himself to overturn the authority of Peter in his archbishopric of Alexandria. He travelled through the patriarchate, ordaining and excommunicating in the most arbitrary manner, attracting to himself many followers, and utterly disregarding all the protestations of the Egyptian bishops, and the sentence of deposition that Peter launched against him. This proselytizing tour was afterwards extended into Palestine. At length, in 325, the Council of Nice arrested Meletius in his reckless career, and fixed him down at Lycopolis as a mere titular bishop, without any active jurisdiction. He did not long survive this sentence.

The Meletians, or, as they called themselves, "The Church of the Martyrs," were chiefly characterized by opposition to the Patriarch of Alexandria. So prominent was this feature that they afterwards sacrificed their orthodoxy, and entered into alliance with the Arians against Athanasius. They continued a distinct sect, however, till the fifth century.

Melfi || Meli.

MELFI, a town of Naples, province of Basilicata, on a high volcanic eminence, 75 miles E.N.E. of Naples, and 34 S. of Foggia. The town has narrow streets; and is defended by walls, now in a ruinous condition, and by an ancient Norman castle. On the 14th August 1851, Melfi was visited by a tremendous earthquake; the ancient cathedral with its tower was laid in ruins, the college and several churches and monasteries were destroyed, 163 houses were thrown down and 278 injured, and more than 600 of the inhabitants perished in the ruins. This town was formerly the capital of the Norman possessions in Southern Italy, and the seat of the baronial councils. The hall where these councils used to meet has been in recent times changed into a theatre. The neighbouring country is rich in wine, which forms the principal article of trade. Pop. 9582.

MELI, Giovanni, born the 4th of May 1740, died the 20th of December 1815, at Palermo in Sicily. Although his works are all written in the vernacular of his native island, he has left a reputation as one of the greatest modern poets of Italy. He early became a graduate in the faculty of medicine, and at the same time displayed a strong sympathy for the philosophical doctrines of Wolfius. His poetical talents, however, made him accepted in literary rather than scientific circles. His Italian verses were admired for their smoothness, and for their delicate sentiments and graceful descriptions. He was induced soon after by the Prince of Campofranco to write his verses in the Sicilian dialect; and while it was with considerable reluctance that he complied with the wishes of the prince, his patron, he nevertheless applied himself to his new vocation with so much energy and taste, that he ultimately gained for himself a place among the brightest names in Italian literature. He took the language of the people, adopted all the grace and strength with which a southern and imaginative race love to clothe their affections and feelings, and applied it to so many different styles, forms, and subjects, as to show its flexibility, aptitude, and inexhaustible power in expressing all forms of sentiment, from the tenderest to the strongest, from the most familiar to the most abstract, without losing its vivacity, harmony, and dignity. Not that he was the first poet who cultivated his native dialect: not a few poets of some note, and above all Vitali, called "*Il Cieco di Ganci*" (the blind poet of Ganci), who was the author of an epic entitled *Sicily Delivered, or the Conquest of Sicily by the Normans*, had preceded Meli; but none of them had enjoyed the advantage of a liberal education. Meli's first poem, *La Fata Galante*, in eight cantos, published before he was twenty, won for him at once a high reputation, which his subsequent works did not diminish. His longest poem, *Don Chisciotte* (Don Quixote), in 12 cantos, is of the mock-heroic type, resembling the famous novel of Cervantes. The *Origine del Mondo*, a satire on the philosophical doctrine of pantheism, is a more original production, and written much in the same style. He has attempted, with admirable success, all styles of poetry except the dramatic; but the species of composition in which he truly excels is in eclogues and anacreontics. The life-like spontaneity of his dialogues, and the direct simplicity of his odes, have seldom been surpassed even by the classic and copious literature of Italy. Meli has been compared to Burns; and his influence over the Italian mind would have been equal to that of the Scottish poet over the English, had Italy enjoyed the social and political advantages of England. Yet the fame of Meli, even during his lifetime, was not confined to the country in whose language he sang. Alfieri, Cesarotti, Rezzonico, Denina, Metastasio, Pananti, and Casti, the greatest men of the day, admired his genius, although they regretted he had not written in the language of Italy. No less a man than Foscolo attempted to translate his poetry into Italian. Professor Rosini of Pisa accomplished this task, although with indifferent success. The translations into the other dialects of Italy have been more happy. Gregorovius, the author of *Wanderings in Corsica*, is at present (1857) translating them into German.

Meli, having studied medicine, was appointed to the chair of chemistry at the university of Palermo, a position which he held till his death. An edition of his essays on scientific subjects was published in Sicily, of which the most esteemed are his *Riflessioni sul Meccanismo della Natura Rapporto alla Conservazione e Riparazione degl' Individui*, Palermo, 1839. A medal was struck in honour of him by order of the Prince of Syracuse, bearing his portrait, with the inscription, "*Anacreonti Siculo*." A tomb was erected in St Francesco, Palermo, by his family; and the inhabitants of Palermo raised a public monument to him in one of the squares of their town. (See *Poesie di Giovanni Meli*, Palermo, 1847; and No. IX. of the *Foreign Quarterly Review*, 1829. (E. F.)

MELISSUS, a philosopher of the Eleatic school, was born in Samos, and flourished about 444 B.C. He took a very active part in the political struggles of his country, and his fellow-citizens honoured him on one occasion with the command of a naval armament. Little more is known respecting his life. Like almost all the philosophers of this epoch of Greek speculation, he composed a treatise on "Being and Nature" (περι φυσέως). He raised a vigorous protest against the empirical sensualism of the Ionic philosophers, among whom he spent his life in his native island. His master, Parmenides, maintained that the senses could furnish nothing certain, and that the study of being, essentially and absolutely one and immoveable, was the only occupation worthy of a philosopher. Zeno, again, had proved to the Ionians that to admit matter is to admit divisibility, which is the condition of extension; but being is indivisible, and hence matter has only a phenomenal existence. Such was the position of antagonism of the two schools when Melissus appeared. He attempted to enlarge the basis of the Eleatic school by borrowing the notions of time and space admitted by the Ionians, but ignored by Parmenides. Having pronounced being to be infinite and one, Melissus applied the same quality to time and space, which led him to their identification. Nothing relative, according to him, can be eternal; motion is impossible, for being is infinite, and motion requires a void. Aristotle (*Met.* i. 8) accuses Melissus of confounding being with matter, but places him higher than Parmenides as a philosopher. As for the existence of the gods, Melissus, like the rest of his school after the time of Xenophanes, declared that it was impossible to arrive at any certainty. Melissus was the last representative of the Eleatic doctrines. (See the Fragments of Melissus, collected by Brandis, *Comment. Eleat.*, Copenhagen, 1813.)

MELKSHAM, a market-town of England, Wiltshire, situated on a slope near the Avon, 26 miles N.W. of Salisbury, and 96 W. by S. from London. It consists of one long and irregular street; and the houses are of stone, and well built. On the other side of the Avon, which is here crossed by a handsome stone bridge, stands a suburb, known by the name of The City. The church, which is believed to be as old as the twelfth century, is in the form of a cross, with a tower, which stood formerly in the centre, but was removed in 1845 to the west end. Melksham has also places of worship for Independents, Baptists, Methodists, and Quakers. There is a large market-house and town-hall, built in 1847, in the Grecian style of architecture. Melksham has, besides, national and British schools, and a savings-bank. In the neighbourhood mineral springs were discovered some time ago, near which have been erected baths and houses for the accommodation of visitors. In the reign of William the Conqueror Melksham seems to have been a place of considerable importance. It has since fallen off; but of late years has been raised by the introduction of the cloth manufacture. Besides this manufacture, and that of ropes, the town has large corn mills, and a considerable trade in leather and malt. It is also the seat of a county court; and petty sessions are held here. Pop. of town (1851) 2931.

MELLONI, MACEDONIO, a distinguished natural philosopher, born at Parma in the year 1800. Before he was of an age to explain or even to understand his own feelings, he delighted to pass whole nights in contemplation out of doors, wandering in the fields—a habit which gave a very great impulse to his scientific genius. With a decision, as resolute as it was prompt, he did not mistake his vocation, but at once applied himself to his favourite science, in which at an early age he made great progress. Little was known at that time among natural philosophers respecting the radiation of heat; and Melloni set early to work to advance the cause of discovery in that department of science. He had scarcely left school when the chair of natural philosophy was offered him at the university of Parma; and hygrometry being the special branch allotted to him, he taught it from 1824 to 1831. In the progress of his researches into the nature of radiation he found occasion to employ an ingenious instrument termed the *thermoscopium*, invented by Nobili, a distinguished physicist of that time, for determining slight variations in the temperature of bodies. Nobili himself appreciated the importance of the results obtained by his young friend, and gave an account of them in an article in the *Bibliothèque de Genève*. In 1831 political events in Romagna and the duchies compelled Melloni to expatriate himself. He found an asylum in France, where he arrived with his thermoscopium. He there became the friend of Arago, the celebrated secretary of the Académie des Sciences, and was subsequently appointed to a professorship in the college of Dôle, in the department of Jura, a situation which his thirst for discovery induced him to resign. He then went to Geneva, where he was welcomed by Pier Prevost and Auguste de la Rive, who placed at his disposal their rich collection of scientific instruments. After six months' assiduous experimenting he succeeded in establishing a number of important facts with regard to the radiation of heat both through solids and liquids. He hastened to Paris to lay his discoveries before the Academy of Sciences, but being received coldly by that body, Melloni resolved to publish the results of his experiments; this led to his being awarded the Rumford medal by the Royal Society of London. After receiving this foreign tribute to his genius, the Institute of France, in the person of Biot, also acknowledged his merits. (See *Mémoirs de l'Académie des Sciences de Paris*, vol. xiv.) The paper submitted to the academy by Melloni is entitled, *Descrizione ed Usi di un Apparecchio proprio a Manifestare ed a Misurare i Fenomeni del Calorico Raggiante.* Melloni had now secured his place among the most eminent men of Europe; and, through the influence of Arago and Humboldt, he was enabled to return to his native country with the consent of Austria, then the ruling power in Italy. Under these circumstances, the King of Naples, at the suggestion of Arago, did not hesitate to appoint Melloni director of the meteorological observatory, then in course of erection on the slope of Vesuvius. Among the many brilliant results obtained by Melloni in this new sphere, must be mentioned his discovery of heat in the lunar light, which led to the solution of one of the most important problems of modern physical science, viz., the analogy of radiant heat to light. At the meeting of the Italian scientific congress at Naples in 1845, Melloni was elected vice-president of the physical section. He was made a member of the commission to establish lighthouses on the coast of the kingdom, when he published a very able popular account of Fresnel's *pharos*. The political events of 1848, and the reaction which followed, again interrupted Melloni's scientific pursuits; for although he had taken no part in politics during his residence at Naples, he was in 1849 ejected from his post simply for the liberal opinions he had once professed, and which he still held. He retired to his villa at Portici, near Naples, where, amid bitterness of spirit and disappointment, his love of science never abated. In 1850 he published there the first volume of *La Termocrosi, o la Colorazione Calorifica*, which he dedicated to Francis Arago and Alexander Humboldt. This compilation, in which he describes his own conclusions, and sketches methodically the progress of science since his first discovery, did not distract his mind from experimental researches. The last years of his life were devoted to the study of electricity, and he communicated many new facts in this branch of science to the *Bibliothèque Universelle de Genève*. Melloni opposed with great discrimination several ideas of Faraday with regard to the diminution of velocity observed in an electric current passing through submarine or subterranean wires, as compared with an equal current passing through wires suspended in the air. The Englishman had made experiments, from which he endeavoured to deduce a confirmation of his theory of conductability, to the conclusiveness of which, however, the Italian demurred.

He died of cholera at his villa of Portici on the 11th of August 1854. Besides his principal work, *La Termocrosi*, which he left incomplete, or at least unpublished, he contributed numerous papers to the *Annales de Chimie et Physique*, the *Comptes Rendus* of the French Academy; the *Bibliothèque de Genève*; the *Atti della Reale Academia di Napoli*; and the *Museo di Scienze e Letteratura*, a Neapolitan periodical, in which may be found his discussions and observations on the action of calamite and the electric current, on polarized light, on ponderable bodies, and also his objections to the theory of Faraday. (For further information respecting Melloni's discoveries, see the *Sixth Dissertation*, chap. vi., sect. 8; also the article HEAT.) (E. F.)

MELMOTH, WILLIAM, a learned member of Lincoln's Inn, was born in the year 1666. He was called to the bar in 1719, was treasurer of Lincoln's Inn for the year 1730, and died in 1743. In conjunction with Mr Peere Williams, Mr Melmoth was the publisher of Vernon's *Reports*, under an order of the Court of Chancery. But the performance for which he is justly held in remembrance is *The Great Importance of a Religious Life Considered*, London 1749; of which above 100,000 copies were sold during the last century. This admirable treatise was published anonymously, and was for some time erroneously attributed to John Percival, the first Earl of Egmont. A new edition of this work, with a memoir of the author and four appendices, was privately printed as a present to the benchers of Lincoln's Inn by Charles P. Cooper, Esq., London, 1849. (See *Memoirs of William Melmoth*, published by his son, 1796.)

MELMOTH, *William*, son of the preceding, was born in 1710. He was bred to the law, and appointed a commissioner of bankrupts in 1756; but the greater part of his life was spent in retirement, partly at Shrewsbury and partly at Bath, where he was distinguished alike for integrity of conduct and for scholarly culture and an elegant taste. He first appeared as a writer in 1742, when, under the name of Sir Thomas Fitzosborne, he published two volumes of *Letters on Several Subjects*, which have been much admired for the just and liberal remarks with which they abound on various topics, moral and literary. In 1747 he published a translation of the Letters of Pliny, in 2 vols. 8vo, which, for elegance, precision, and correctness, is one of the best versions of a Latin author that has appeared in our language. In 1753 he published a translation of Cicero's Letters, in 3 vols., which were followed up in 1773 and 1779 by richly annotated translations of the treatises *De Amicitia* and *De Senectute*. In his remarks on the treatise *De Amicitia* he combated the opinion of Lord Shaftesbury, who had imputed it to Christianity as a defect, that it contained no precepts in favour of friendship; and also that of Soame Jenyns, who had represented this very omission as a proof of its divine origin. The concluding work of Mr Melmoth consisted of memoirs of his father, published in 1796. He died at Bath on the 15th of March 1799, at the age of eighty-nine.

MELODICA, a keyed instrument in the form of a harpsichord, and having a flute register of three and a half octaves, from the lowest G of the violin upwards. It was invented by J. A. Stein at Augsburg in 1770.

MELODICON, a keyed instrument invented by Peter Riffelsen at Copenhagen in 1803. Its sounds were produced by the friction of pointed rods upon a revolving cylinder of steel. Riffelsen had previously constructed another instrument with tuning-forks of different dimensions.

MELODION, an instrument invented by Dietz at Emmerich in the Netherlands. It was in the form of a small harpsichord, with a pedal which moved a wheel. The sounds were produced by metal rods caused to vibrate by the friction of the wheel.

MELODY. See MUSIC.

MELPOMENE, in fabulous history, one of the muses, daughter of Jupiter and Mnemosyne, who presided over tragedy. Horace has addressed the finest of his odes to her, as to the patroness of lyric poetry. She was generally represented as a young woman with a serious countenance; her garments were splendid; she wore a buskin and a garland of vine leaves, and held a dagger, or the club of Heracles, in one hand, with a sceptre and crown in the other.

MELROSE, a burgh of barony of Scotland, Roxburghshire, on the Tweed, near the N. foot of the Eildon Hills, 36 miles S. of Edinburgh, and 12 N.W. of Jedburgh. The town probably derives its name from *Moel* or *Mull-rhos*, a point or headland in the river; and the site was occupied by a Culdee house founded in 635. This was superseded by the Cistercian abbey, begun by David I. in 1136, and completed in 1146. This building having been destroyed by the English under Edward II. in 1322, was rebuilt by Bruce four years afterwards; and the heart of that monarch, after having been carried to Spain by Douglas, was, on the death of that earl brought home and buried beneath the high altar. The abbey was completed by James IV.; but was again destroyed by the English in 1545. Although this fine building suffered considerably from the hands of the Reformers, the main cause of its present ruinous condition must be traced to the hostile incursions of the English, and to the carelessness and depredations of later times, when the stones were frequently carried off and employed in building other edifices. The church was laid out in the form of a cross, of which the length of the nave and choir was 258 feet, and the breadth 79; the length of the transept 130 feet, and the breadth 44. The building was surmounted by a tower, part of which is still standing along with the walls of the nave, choir, and transept. The rest of the abbey, however, has been destroyed, except a portion of the walls of the cloisters. Its architecture is not reducible to any of Rickman's styles of English Gothic. It more nearly approaches to continental structures, especially Strasburg cathedral; and the whole building is profusely ornamented with rich and exquisite carved work. Some of the piers are crowned with foliage, so delicately chiselled, that a straw may be thrust in between the various stalks and leaves. The window and door in the south transept are considered the most perfect parts of the building, and are very richly decorated. The eastern window is also much admired for the symmetry of its form and the richness and delicacy of its ornaments. Its dimensions are 36 feet in height by 16 in breadth. The grave of Alexander II. is pointed out here, as lying under a marble slab not far from the high altar; and many others, noblemen and priests, are buried in the abbey, including several of the Douglas family. A beautiful description of Melrose is given by Sir Walter Scott in the *Lay of the Last Minstrel.* Pop. (1851) of town, 966.

MELSUNGEN, a town of Hesse-Cassel, situated on the left bank of the Fulda, 13 miles S. of Cassel. The town is walled, with four gates; and contains a castle, church, and hospital. The manufactures consist of woollen cloth, leather, tiles, &c.; and there is a considerable trade in wood and linen. Pop. 4220.

MELTON-MOWBRAY, a market-town of England, in Leicestershire, situated at the confluence of the Wreak and Eye, 14 miles N.E. of Leicester, and 92 N. by W. of London. The town is well and substantially built, chiefly of brick; and consists of two main streets. The parish church is a large and handsome Gothic building, in the form of a cross, with a lofty and richly adorned tower in the centre. There are also churches for Independents, Wesleyan and Primitive Methodists, and Roman Catholics; several schools and alms-houses; besides a subscription library, news-room, and theatre. Melton owes its prosperity and celebrity to its being the centre of the hunting district, and the seat of the Melton Hunt. It is on this account resorted to by the leading sporting men of England, and by some from other countries, during the season, which lasts from November till March. Upwards of 800 horses, with their grooms, &c., may be accommodated in the excellent stables of Melton; and in the neighbourhood there are many hunting seats. The chief manufactures of the place are lace and hosiery; and the trade consists chiefly in pork pies and Stilton cheese, which is made here, though it takes its name from Stilton in Huntingdonshire, where it was first sold. John Henley the orator was born here in 1692; and Melton is also remarkable as the scene of a defeat of the parliamentary troops by the royalists in 1644. Pop. (1851) 4391.

MELUN, a town of France, capital of the department of Seine-et-Marne, is pleasantly situated on the Seine, 27 miles S.S.E. of Paris. The town stands on both sides of the river, especially on a slope on the right bank, and partly on an island joined by two bridges to the other parts of the town. The oldest part of Melun is that on the island; and it is well, though irregularly built, containing a large prison, a ruined palace, and the church of Notre Dame. The part on the right bank, called St Aspais, includes a large and regularly built square, an old Gothic church, the ruins of an old abbey, the prefecture, formerly a Benedictine abbey, a theatre, baths, &c. On the left side of the river stand the cavalry barracks. The town has a public library, as well as a college and several schools. Melun has manufactures of woollen and linen cloth, leather, china, plaster, &c.; and there is a considerable trade in grain. This town was anciently called Melodunum, and was taken by the Romans under Labienus, one of Cæsar's generals. It was afterwards captured by the English under Henry V. in 1420, but was recovered by the French fifteen years afterwards. Pop. (1851) 7528.

MELVILLE, ANDREW, a Scottish divine of distinguished talents and learning, was born at Baldovy in Forfarshire on the 1st of August 1545. His father, Richard Melville, who was connected with a family which boasted its descent from the blood-royal, was slain at the disastrous battle of Pinkie, fought on the 10th of September 1547, when Andrew, the youngest of nine sons, had only completed his second year. He lost his mother during the same year, and the care of the orphan boy devolved upon his eldest brother Richard, who afterwards became minister of the adjacent parish of Marytoun. As he early discovered great aptitude for learning, he was removed to Montrose, where he was instructed in the rudiments of the Latin language. In the year 1559 he was sent to the university of St Andrews, where he became a student in St Mary's College, and greatly distinguished himself by his early proficiency in classical learning, particularly in his knowledge of Greek, a language at that time unknown even to the lecturer on Aristotle of his university. Melville left this university with the reputation of "the best philosopher, poet, and Grecian of any young master in the land;" and in the autumn of 1564, when he had completed his nineteenth year, he proceeded to Paris with the view of prosecuting his studies at the university of that city, then at the height of its celebrity. Here Melville enjoyed the advantage of hearing the prelections of Turnebus, professor of Greek in the Royal College; of Mercier and Quinquarboreus, professors of Hebrew and Chaldee; and of the celebrated Peter Ramus, who had greatly distinguished himself by his strenuous opposition to the philosophy of Aristotle. In addition to his other engagements, young Melville commenced the study of civil law, at that time taught by Balduinus, or Baudouin, a very eminent civilian of Paris. During the second year of his residence he had attained to such proficiency in the Greek language, that he was able to speak it with great fluency and copiousness. He left Paris in the year 1566, and repaired to the university of Poitiers to prosecute the study of law. Here, owing to his great celebrity, he was appointed a regent in the college of St Marceon, though he was only twenty-one years of age. He continued to prosecute his legal studies for three years at Poitiers; but owing to political disturbances he was ultimately compelled to seek a residence elsewhere. Leaving behind him his books and other effects, and fixing a small Hebrew Bible in his girdle, he, in company with a Frenchman, set out for Geneva. When the two pedestrians reached the gates of that city, their money was all but entirely spent; Melville, however, had the good fortune to obtain, through the influence of Beza, the professorship of humanity in the academy of Geneva, and was thus enabled to support for a time his less fortunate companion.

Geneva was at this time a most conspicuous bulwark of the Reformation. It afforded an asylum to many persecuted Protestants of eminent piety and learning. The academy of Geneva, which was a university without the name, could boast of various professors of the highest reputation. The chair of Calvin, its first and most celebrated professor of divinity, was now occupied by Beza, who was likewise a man of eminent talents, and who with his profound knowledge of theology united many of the graces of polite literature. Melville, still eager to learn, became a student under this venerable professor; and acquired a knowledge of Syriac from Bertram, the professor of oriental languages. In the year 1572 the atrocious massacre of St Bartholomew compelled many of the French Protestants to abandon their native country and seek refuge in Geneva. Melville had the good fortune on this occasion to make the acquaintance of the celebrated scholar and thinker, Joseph Scaliger, for two years professor of philosophy at Geneva. He also heard the lectures of Bonnefoy on oriental jurisprudence, who, along with Hotman, another distinguished refugee, was paid by the magistrates of Geneva for delivering lectures on civil and ecclesiastical law.

After having retained his professorship for five years, he was at length induced by the urgent solicitations of his friends in Scotland to revisit his native country. He according left Geneva in the spring of 1574; and in passing through Paris engaged in a controversy, which lasted several days, with one James Tyrie, one of the antagonists of Knox, at the college of the Jesuits. He arrived in Edinburgh in the beginning of July 1574.

Melville had already distinguished himself by his Latin poetry, and his reputation as a man of talents had reached his native country. It was about this period that he made his first appearance as an author. His earliest work was entitled *Carmen Mosis, ex Deuteron. cap. xxxii. quod ipse moriens Israeli tradidit ediscendum et cantandum perpetuo, Latina paraphrasi illustratum. Cui addita sunt nonnulla Epigrammata, et Jobi cap. iii. Latino carmine redditum. Andrea Melvino Scoto auctore*, Basileæ, 1574, 8vo. The Earl of Morton, regent of the kingdom, was desirous of retaining him in the capacity of a domestic chaplain; but he had no wish to become a courtier; and he was persuaded that his labours would be most available to his countrymen if he were placed in one of the universities. On the death of John Douglas, who had accumulated the offices of Archbishop of St Andrews, provost of St Mary's College, and rector of the university, a proposition was made for placing him at the head of the college; but on being very strongly urged to accept of a similar appointment at Glasgow, he was finally induced to give it the preference. On his installation as principal of the Glasgow university in November 1574, he found that institution in a very unsatisfactory condition. When he commenced his academical labours his only coadjutor was Peter Blackburne, who officiated as a regent, and managed the scanty revenues of the foundation. The exertions of the principal himself to elevate the teaching and improve the character of the university were quite prodigious. He initiated his students in the principles of Greek grammar; introduced them to the Dialectics of Ramus and the Rhetoric of Talæus; read with them the best classical authors, as Virgil and Horace among the Latins, and Homer, Hesiod, Theocritus, Pindar, and Isocrates among the Greeks; taught them the Elements of Euclid, with the arithmetic and geometry of Ramus, and the geography of Dionysius; read with them Cicero's Offices, Paradoxes, and Tusculan Questions, the Ethics and Politics of Aristotle, and certain of Plato's Dialogues; expounded natural philosophy; taught the Hebrew language, accompanied with a praxis upon the Psalter and books of Solomon; initiated the students into Chaldee and Syriac; and, to complete the theological curriculum, went through all the common heads of divinity, according to the order of Calvin's *Institutes*, besides giving lectures on the different books of Scripture. This course of study was completed in six years. After some time, however, he succeeded in increasing the staff of professors, and restricted himself to divinity and oriental languages. The learning, talents, and energy of Melville speedily raised this university from its ruinous condition, and secured for it the reputation of being the first seminary in the kingdom. Students were attracted from all parts of the country, and among these were not a few graduates from St Andrews, who were disposed to learn what their former masters could not teach. Various individuals who afterwards rose to eminence were here trained under his discipline. Melville's influence in advancing the literature of his native country was great and lasting; nor was it less considerable in improving the condition of the Scottish church. He was a member of the General Assembly convened at Edinburgh in March, as well as that convened at the same place in August 1575. The lawfulness of episcopacy was debated in this latter assembly; and he there maintained the negative side of the question in a speech which, as Spotswood admits, "was applauded by many." For the more mature discussion of this subject, the assembly appointed a committee of six, of which Melville formed one, who presented a report expressive of a mild but essential hostility to episcopacy. This report was approved by the assembly held in April 1576; and those bishops who had not already undertaken some parochial cure, were enjoined to select particular parishes for the exercise of their pastoral functions. This was the first step towards the abolition of diocesan episcopacy in Scotland. Of the assembly held in Magdalene Chapel at Edinburgh in the month of April 1578, Melville was chosen moderator. The Second Book of Discipline now received the sanction of this ecclesiastical judicature; and it was resolved that bishops should no longer be described as *lords*, but should be addressed like other ministers.

After a residence of six years at Glasgow Melville was removed to St Andrews, where he was installed as principal of St Mary's College, in the month of December 1580. The university of St Andrews had very recently been subjected to a salutary reform, and this college had been appropriated to the study of divinity. The office of primarius professor of divinity was then conjoined, as it still continues to be, with that of principal. Here, again, however, owing to the temporary incompleteness of the university, the enthusiastic principal, in addition to his own lectures on systematic theology, "taught learnedly and perfectly the knowledge and practice of the Hebrew, Chaldee, Syriac, and rabbinical languages." In this new situation he had to contend with new difficulties; but his superior talents and learning, with the firmness and consistency of his personal character, enabled him to overcome all opposition.

Melville took a prominent part in the subsequent ecclesiastical struggle of his country against the restoration of popery. At a General Assembly held at St Andrews in April 1582, he was again elected moderator, and assisted in drawing up a vigorous remonstrance, complaining of their grievances, and craving redress. A deputation of the members, with the moderator at its head, was named for the purpose of presenting this remonstrance to his majesty, who was then residing at Perth. It was accordingly presented to the king in council; and on its being read, the Earl of Arran asked with an angry countenance, "Who dare subscribe these articles?" "We dare," said the undaunted Melville, and immediately signed his name, the other commissioners following his example. The minions of power were overawed by their intrepidity, and dismissed them without any formal censure.

On one occasion Melville, in a public sermon, took the liberty of animadverting on certain public abuses, when the provost of the city abruptly quitted the church in the middle of the discourse, not without muttering his high displeasure at the unsparing zeal of the preacher. The gates of St Mary's College exhibited placards threatening to bastinade the principal, to set fire to his lodgings, and to expel him from the city. But in the midst of these excitements he not only continued firm and undismayed, but summoned the provost before the presbytery for contempt of divine ordinances. He was soon afterwards exposed to danger from another quarter. He was cited to appear before the Privy Council on the 17th of February 1584, to answer to a charge of having, on the occasion of a fast kept during the preceding month, uttered certain seditious and treasonable words in his sermon and prayers. Furnished with ample testimonials of his loyalty, he repaired to Edinburgh, and having appeared before the council, he entered into a full explanation and defence of the expressions which he had actually employed. The Privy Council resolved. however, to proceed against him, when he declined its jurisdiction in a written protest. On the reading of Melville's declinature the king and Arran were roused to unseemly rage; but they had to deal with a man whom the frowns of royalty could not intimidate, and he pleaded his own cause with the most unshaken firmness and resolution. In the course of his speech he appealed to the authority of the Scriptures; and unclasping a Hebrew Bible that was suspended at his girdle, he threw it on the council table, and challenged any of his judges to show that he had exceeded his instructions. He was, however, found guilty of behaving irreverently before the council and of declining its jurisdiction, and was sentenced to be imprisoned in the castle of Edinburgh, and to be further punished in his person and goods at the pleasure of the king. On learning that the place of confinement was changed to Blackness Castle, a dreary dungeon kept by a dependent of the Earl of Arran, he escaped from Edinburgh, and next day proceeded to Berwick. This rigorous treatment of so learned and eminent a man excited no small degree of popular indignation. Having obtained permission to visit London, he proceeded on his journey, bearing with him instructions from the exiled nobles who were then residing at Berwick. During the ensuing month of July he paid a visit to the universities of Oxford and Cambridge, and was received with great marks of respect. After an absence of twenty months, Melville and the banished lords returned to Scotland in the beginning of November 1585. He lost no time in using his best endeavours for the recovery of those liberties of which the church had recently been deprived. He undertook a mission to various parts of the kingdom for the express purpose of securing a united effort among his brethren, to effect a change in the ecclesiastical polity of the country.

During the absence of Melville the university of St Andrews had witnessed many vicissitudes; but in the month of March 1583 its zealous and learned principal returned to the scene of his former labours. When Du Bartas, an envoy from the King of Navarre, accompanied King James to St Andrews, they came to hear a lecture from Melville; and he pronounced an extempore discourse, which is said to have given "satisfaction to all the hearers except his majesty, who considered some parts of it as levelled against his favourite notions of church government." Aroused by the efforts made by the archbishop to induce his majesty further to encourage prelacy, the intrepid reformer, despite the threats of the king, delivered an elaborate discourse on the following day, directed against the positions of the archbishop, and characterized by great eloquence and power; on which the royal auditor condescended to deliver a speech, enjoining all to respect and obey the archbishop. The imperial disputant afterwards deigned to partake of a collation in the college, and was regaled with "wet and dry confections and all sorts of wine."

Of the General Assembly held in June 1587 Melville was elected moderator; and on the 17th of May 1590 he was present at the coronation of the queen, and recited a Latin poem which he had composed for the occasion, and which was immediately published (Στεφανίσκιον, *ad Scotiæ Regem, habitum in Coronatione Reginæ,* 17 *Maii* 1590, *per Andream Melvinum,* Edinb. 1590, 4to). His antagonist, Adamson, who died on the 19th of February 1592, had been deprived of his office, together with all its emoluments, by the king. Left to poverty and contempt, Melville hastened to pay him a visit, and not only procured contributions from his friends at St Andrews, but even continued for several months to support him from his private resources. The death of this accomplished and unfortunate prelate was speedily followed by the formal restoration of presbytery; and Melville, after being again elected moderator of the General Assembly of May 1594, subsequently accompanied the king on his expedition against the popish lords, after the battle of Glenlivet; and his majesty, who had requested their attendance, found him a very faithful and able counsellor. When an attempt was afterwards made to recal the popish lords from banishment, Melville, with other commissioners, was admitted to a private audience of the king, when, taking his majesty by the sleeve, and calling him "God's silly vassal," he proceeded to address him in a strain which was "perhaps the most singular, in point of freedom, that ever saluted royal ears, or that ever proceeded from the mouth of a loyal subject, who would have spilt his blood in defence of the person and honour of his prince." While some applaud the courage of this undaunted presbyter, others may be equally disposed to condemn him as guilty of unwarrantable insolence to his sovereign. For several years ensuing the king made repeated attempts to regulate the church according to his own arbitrary notions, but constantly found a strenuous opponent in the worthy principal of St Mary's. After repeated and fruitless endeavours on the part of the king to prevent Melville from occupying a seat in the General Assembly of the church, his majesty at last, by his sole authority, commanded him, under pain of treason, to confine himself within the walls of his own college; a sentence afterwards relaxed by the intercession of the queen, so as to permit him to move within a circuit of six miles from St Andrews.

Andrew Melville was one of the eight presbyters called to London by King James on his accession to the English throne, for the overt purpose of restoring the tranquillity of the church, but, as is confidently believed, with the secret intention of circumventing this formidable scourge of episcopacy. Melville and his colleagues, however, conducted themselves with so much firmness and skill, that they were dismissed with unequivocal marks of approbation on the part of those who were present. "The English nobility," says M'Crie, "who had not been accustomed to see the king addressed with such freedom, could not refrain from expressing their admiration at the boldness with which Melville and his associates delivered their sentiments before such an audience, at the harmony of views which appeared in all their speeches, and the readiness and pertinency of the replies which they made to every objection with which they were urged."

Before quitting the metropolis various artful but fruitless expedients were adopted for corrupting the integrity of the staunch Presbyterians of the north. They were, besides, treated to lectures on the beauties of episcopacy, and permitted to witness one of its most imposing spectacles, which only served, however, to excite ridicule in the irreverent minds of the stern presbyters, and which found vent in a trenchant epigram of Melville's (*Melvini Musæ,* p. 24, anno 1620, 4to), who was obliged to appear at Whitehall and answer for his obnoxious verses. On appearing before the king and council, Bancroft, Archbishop of Canterbury, began to expatiate on the aggravated nature of his offence, which he described as coming within the definition of treason. "My lords," he indignantly exclaimed, "Andrew Melville was never a traitor; but there was one Richard Bancroft (let him be sought for), who, during the life of the late queen, wrote a treatise against his majesty's title to the crown of England; and here is the book." Bancroft, who was totally unprepared for such an act of retaliation, sat in mute astonishment, while Melville proceeded to accuse him of profaning the Sabbath, and of silencing and imprisoning faithful preachers of the gospel for scrupling to conform to the vain and superstitious ceremonies of an anti-Christian hierarchy. He gradually advanced so near this pontiff as to shake his lawn sleeves; and calling them Romish rags, he thus continued to address him: "If you are the author of the book called *England Scottizing for Geneva Discipline,* then I regard you as the capital enemy of all the Reformed churches in Europe, and as such I will profess myself an enemy to you and your proceedings, to the effusion of the last drop of my blood; and it grieves me that such a man should have his majesty's ear, and sit so high in this honourable council." After some altercation, Melville was informed that he had been found guilty of *scandalum magnatum*, and was to be committed to the custody of the dean of St Paul's till the king should signify his pleasure as to his further punishment. On the 26th of April he was again summoned before the council. The King of Great Britain, France, and Ireland had recourse to the expedient of stationing himself in a closet where he could hear without being seen; and he received the appropriate reward of hearing himself mentioned with the utmost freedom of speech by the most undaunted of his subjects. By a most inquisitorial sentence, worthy of Rome or Toledo, he was committed as a prisoner to the Tower. His nephew, who had written an epigram on the superstitions of the church, was commanded to fix his residence at Newcastle-upon-Tyne, and not to move beyond a distance of ten miles from that town.[1] Their brethren were permitted to return to Scotland, but were each of them restricted to particular limits.

For the space of about ten months the prisoner was subjected to the most rigorous treatment; no person was allowed to visit him; he was not permitted to retain a servant, and was even denied the use of pen and ink. But his manly spirit was still unsubdued, and he endeavoured to amuse his solitary hours by composing Latin verses, which, with the tongue of his shoe-buckle, he engraved on the walls of his prison-house. From these unnecessary restraints he was at length released by the intercession of some of his friends at court, and particularly of Sir James Semple, but the king could not yet be induced to open the doors of his prison. At the expiration of four weary years he was released at the intercession of the Duke of Bouillon, who invited him to fill the chair of biblical literature in the Protestant university of Sedan. He was now in the sixty-sixth year of his age, and had long filled an honourable and conspicuous station in his native land, to which he felt that strong attachment which his countrymen so generally feel. It was accordingly with some degree of reluctance that the brave old presbyter prepared for this voyage to France. He embarked, however, on the 19th of April 1611, and having spent a few days at Rouen and Paris, he arrived at Sedan in the course of the ensuing month. In this university he was associated with several of his countrymen, which served to lighten his banishment; yet he did not cease to cherish some lingering though faint hope of being permitted to deposit his bones in the land of his fathers. His naturally vigorous constitution had been impaired, however, by his protracted imprisonment; and he terminated his eventful life at Sedan in the year 1622, at the age of seventy-seven.

Melville was small in stature, and was alike conspicuous for his vivacity of body and mind. His elasticity of spirit, which he appears to have retained till the last years of his life, was accompanied with a warm and impetuous temperament, which, however, was free from all personal malignity. From his early youth he was distinguished by fervid and consistent piety. He was a man of the most unblemished integrity; nor did his enemies, who were sufficiently numerous, venture to charge him with sordid or selfish motives of conduct; their accusations chiefly relate to his want of personal reverence for the king, and to his want of veneration for bishops. In private life he appears to have been very amiable and affectionate: if his indignation was easily roused, it was also easily appeased. Melville was unquestionably possessed of very uncommon talents, and he had acquired an ample and varied store of erudition. Such was his indifference to literary reputation, however, that although so capable of writing in prose or verse, he committed very few works to the press. In the excellent *Life of Andrew Melville* by Dr M'Crie, 2 vols. 8vo, 1819, will be found an enumeration of his works, to which may be added a MS. *Commentarius in divinam Pauli Epistolam ad Romanos, auctore Andrea Melvino Scoto.*

MELVILLE, *Sir James*, whose name is familiarly known to the readers of Scottish history, was born in the year 1535. He was the third son of Sir John Melville of Raith in Fifeshire, by his wife Helen, the eldest daughter of Sir Alexander Napier of Merchiston. At the age of fourteen he had the misfortune to lose his father, who, having espoused the Reformed doctrines, was, at the instigation of Archbishop Hamilton, brought to the scaffold at Stirling, convicted of high treason. The archbishop having found means of seizing upon his estate, Melville's widow and children were reduced to a state of penury. Through the influence of the queen-regent, young Melville was attached to Monluc, Bishop of Valence, as a page of honour. After a series of curious adventures, the young Scot reached Paris, where, during his master's absence at Rome, he was left to improve his education. Young Melville having accidentally come under the notice of Montmorenci, the great constable, after obtaining the bishop's consent, took him into his service. In this position he witnessed several campaigns in France and Flanders during 1553. The kindness of his patron procured him a pension from the king during the following year.

In 1557 he bore arms at the battle of St Quentin, where the constable's army was totally defeated, and he was himself wounded and taken prisoner. He attended the constable during his captivity; from which he was delivered by the treaty of Cateau-Cambresis, concluded in the year 1559. In the course of the same year the king, at Montmorenci's suggestion, sent him on a secret mission to Scotland, where, under the pretext of paying a visit to his relations, he was instructed to use his best endeavours for ascertaining the real views of the Prior of St Andrews and his adherents. During Melville's absence the constable, his master, had the misfortune to kill his sovereign, Henri II., in a tournament, which led to his removal from the court. Melville, although received with the greatest kindness, judged it expedient to try his fortune in another country, and he now directed his views towards Germany. He entered the service of the elector palatine, and was employed by that prince on various diplomatic missions. In company with the elector's second son Casimir he visited France during 1561; and he there made a tender of his services to Queen Mary, who was on the eve of returning to Scotland. She received him very graciously, and urged him "when he wes to retire him out of Germany, to com hame and serue hir Maieste, with friendly and fauorable offers."

Having received communications from Moray and Maitland, requiring him, in the name of their royal mistress, to return home for the purpose of being employed in some affairs of consequence, Melville took leave of the elector palatine, and after executing a commission to the Queen of England with which he had been intrusted by his German master, he directed his steps towards Scotland, and presented himself to Mary at Perth on the 5th May 1564. The Queen of Scots received him graciously, and engaged him in her service, bestowing upon him a pension of a thousand marks.

---

[1] James Melville was afterwards permitted to reside at Berwick, where he died on the 19th of January 1614, in the fifty-ninth year of his age, and the eighth of his banishment. He was twice married, and left several children. He appears to have been an upright and disinterested man: his zeal, less fiery than that of his uncle, was equally uniform and consistent, nor did the offer of a bishopric shake his attachment to presbytery. His talents were much inferior to those of his uncle. He is the author of various works in the Latin and Scottish languages. His Diary, recently printed for the Bannatyne Club, contains much curious information relative to the ecclesiastical and literary history of that age.

After an interval of a few months, Melville was intrusted with an embassy to the Queen of England. Of his proceedings on this occasion he has given a circumstantial and characteristic account, in which the characteristic weaknesses of Elizabeth are very prominently displayed. He continued his attendance at court after the queen's marriage with Darnley, and must sometimes have had a difficult and delicate part to perform. On the birth of a prince, 19th June 1566, he was instantly despatched to convey the intelligence to Elizabeth, and returned to his royal mistress with a choice collection of court gossip respecting the serious manner in which Elizabeth took to heart the news which had just come from Scotland of the birth of a prince. During the following year, when Mary was intercepted by the Earl of Bothwell, he was among her other attendants, and along with her was conducted to Dunbar Castle, but was only detained for a single day. Amidst the civil commotions which succeeded he appears to have pursued a prudent and cautious tenor of conduct, and to have abstained from involving himself too deeply with either of the adverse factions. He had adhered to the queen till she was committed to Lochleven Castle. During the eventful regency which ensued Melville had some concern in public affairs; and after the king received the reins of government into his own hands he was appointed a gentleman of the bed-chamber, and a member of the Privy Council. He was not, however, acceptable to James's favourite, the Earl of Arran, through whose influence his name was in 1584 expunged from the list of privy councillors. He did not entirely lose the king's favour, but was soon afterwards consulted on various occasions; and was in 1590 attached to the queen's household.

When the king succeeded to the crown of England his majesty was anxious to retain his services, but he being desirous to "spend the remainder of his days in contemplation, begged his Majestie's permission thereto." He died on the 13th of November 1617, at the mature age of eighty-two. (Wood's *Peerage*, vol. ii., p. 112.) From the eldest brother of Sir James Melville is descended the noble family of Leven and Melville.

Melville employed some portion of his declining age in writing memoirs of his public life; and the work was published by his grandson, George Scott of Pitlochie, sixty-six years after the death of the author. *The Memoirs of Sir James Melvil of Hal-hill; containing an impartial Account of the most remarkable Affairs of State during the last Age*, &c., London, 1683, fol.; Edinburgh, 1735, 8vo.; Glasgow, 1751, 12mo. The fidelity of the editor, however, was liable to strong suspicion, which was naturally augmented by the consideration that no early copies of the memoirs could be traced in any public or private library. But a manuscript, apparently in the handwriting of the author, was at length discovered in the collection bequeathed to the Rose family by the Earl of Marchmont. From this manuscript the work was printed for the Bannatyne Club: *Memoirs of his own Life by Sir James Melville of Halhill.* M.D.XLIX.–M.D.XCIII.; Edinburgh, 1827, 4to. Melville's memoirs, in this authentic form, are a most valuable accession to the stock of original materials for Scottish history.

MELVILLE BAY, an inlet of Baffin's Bay, on the coast of Greenland, Lat. 76. N., Long. 60. to 64. W. It was from this bay that the last despatch was received from the unfortunate expedition of Sir John Franklin, July 1845.

Melville Island, an island lying off the N. coast of Australia, between 11. 8. and 11. 56. S. Lat., and 130. 20. and 131. 24. E. Long. It is separated from the mainland on the E. by Dundas Strait, which is 15 miles in breadth, and on the S. by Clarence Strait; while on the W. it is separated from Bathurst Island by Apsley Strait, 46 miles in length, and varying from 1½ to 4 in breadth. The coasts of the island, on all sides but the N., are high, and in many places bold and precipitous; but on the N. the coast is low, and abounds in shallow bays. The whole island is well wooded, and in some places very thickly, except on the W. coast, where the trees are few and stunted, by reason of the N.W. monsoon. The height of the central part is 100 or 130 feet; and throughout the whole island vegetation is luxuriant, and many sorts of timber, useful for carpentry and shipbuilding, are obtained here. In all the creeks of Melville Island alligators abound; and turtles are found in great numbers on all the coasts, except that of Apsley Strait. The animals found in the island closely resemble those of Australia. The climate from October till April or May is unhealthy, on account of the excessive heat and moisture of the atmosphere. The N.W. monsoon begins about November, and rain falls in great abundance during all the hot season. From May till September the weather is dry and pleasant, though the heat even then is great. The inhabitants are divided into small tribes, and lead a wandering life, being chiefly employed in hunting. They are not much inclined to intercourse with Europeans.

MEMEL, a seaport of E. Prussia, in the government of Königsberg, is situated at the entrance of a large inlet of the Baltic called the Kurische Haff, near the mouth of the Dange, 74 miles N.N.E. of Königsberg; Lat. of lighthouse 55. 43. 7. N., Long. 21. 6. 2. E. The town consists of three parts—the old town, the new town, and Frederick's Town; besides several suburbs. It was surrounded by walls in the time of the Teutonic knights, and is still fortified, having a citadel with four bastions, built in 1250, and part of which is now employed as a prison. Memel contains two Lutheran churches, one Calvinistic, and one Roman Catholic church, a synagogue, several schools and benevolent institutions, two arsenals, an exchange, and a theatre. The harbour, which is spacious and secure, is obstructed by a bar at the entrance of the Kurische Haff; where the depth of water is never more than 18, and sometimes as low as 13 feet; so that large vessels are obliged to load and unload in the roads. The harbour is commanded by the citadel; and at the entrance stands the lighthouse, 128 feet high, with a very brilliant stationary light, which is visible to the distance of 20 miles. The principal articles of manufacture are woollen cloth and soap; and there are also in Memel breweries, distilleries, shipbuilding yards, &c. The position of the town on the Baltic, and its proximity to the Russian frontier, render it a place of considerable trade. The following is an account of the number and tonnage of the vessels which have entered and left the port from 1851 to 1854:—

	Entered.		*Cleared.*	
Year.	Ships.	Tonnage.	Ships.	Tonnage.
1851	1104	143,210	1198	141,808
1852	740	92,083	760	97,132
1853	984	129,591	1007	134,380
1854	1766	208,984	1570	183,266

The number of vessels belonging to Memel was in 1855, 85, and in 1856, 88. The principal exports are,—timber (chiefly oak and fir), corn, hemp, flax, oil, wool, hides, tallow, &c.; and the imports consist of salt, coal, herrings, cutlery, cotton, yarn, &c. The town was partially destroyed by fire in 1854. Pop. 10,769.

MEMMI or **Di Martino, Simone**, a celebrated Italian painter, was born about 1285 at Siena. According to Vasari, he was a pupil of Giotto, and in 1298 was engaged under that master in the mosaic of the Navicella at Rome. But as Memmi was then only fourteen, Vasari's account has been doubted by Rumohr, Lanzi, and others. He was, however, a close student of Giotto's works, and at an early age painted the portico of St Peter's at Rome in the style of that artist. So notable was this performance that he was immediately invited to the papal court at Avignon. Here he became intimate with Petrarca; and the respective arts of the painter and the poet were employed to commemorate their mutual friendship. Memmi painted the portrait of Laura, the lady-love of his friend the poet; Petrarca, in return, immortalized Memmi in two of his sonnets. After producing at Avignon many good pictures, both in fresco and distemper, Memmi returned to Siena, and was employed in the decoration of the palace and cathedral of that city. Invited to Florence by the general of the Augustines, he painted in the chapter-house of Santo Spirito a masterly and elaborate picture of the Crucifixion. Soon after his return to Siena his last illness attacked him. He contrived, however, to travel to Avignon, and there he died in 1344.

A few of Memmi's numerous productions still exist. In the Campo Santo at Pisa are his stories from the life of San Ranieri, and his famous "Assumption of the Virgin." His histories of Christ, San Domenico, San Pietro Martire, and part of his history of the Preaching Friars, are found in the chapter-house of the Spanish Friars at Florence. Petrarca's manuscript copy of *Servius on Virgil*, which is preserved in the Ambrosian Library of Milan, contains a miniature of exquisite conception by Memmi. It represents Virgil engaged in composition, and raising his eyes heavenward to catch the ray of inspiration. A shepherd, a husbandman, and a warrior standing before him intimate the respective subjects of the Bucolics, Georgics, and Æneid. The function of the critic is indicated by a representation of Statius drawing aside a veil of delicate transparency.

"Memmi's works," says Vasari, "prove that he possessed great power of imagination, and was well versed in the best methods of composing his groups in accordance with the manner of those days." A great tribute is paid to him by Petrarch: "I am acquainted," he says in one of his letters, "with two illustrious painters,—Giotto the Florentine, of great fame among moderns, and Simone of Siena." (Vasari's *Lives of the Painters*, and Lanzi's *History of Painting*.)

MEMMINGEN, a town of Bavaria, circle of Swabia, situated on a tributary of the Iller, 43 miles S.W. of Augsburg. The town is walled, and contains a handsome town-hall, an arsenal, barracks, several churches, schools, hospitals, &c. It has manufactures of woollen, cotton, and linen fabrics, stockings, ribbons, tobacco, iron and copper wares, &c.; and there is a considerable trade in salt, wool, corn, and the various manufactures of the place. Memmingen is noted as the scene of a victory gained by the French under Moreau over the Austrians, 10th May 1800. Pop. 7200.

MEMNON, the *Resolute* or *Steadfast* (from μένω). 1. The son of Aurora and Tithonus, a hero of the Trojan war. Homer mentions him in the *Odyssey* as remarkable for his beauty, and alludes to his having slain Antilochus, the son of Nestor. (*Odyss.* iv. 188, xi. 521.) Hesiod speaks of him as king of the Ethiopians. (*Theog.* 984-5.) Later writers give us much fuller accounts of Memnon; but it must not be therefore concluded that he was not until then celebrated; for Arctinus of Miletus, who is assigned to the middle of the eighth century B.C., wrote a poem, *Æthiopis*, of which his history probably formed the main object. (Heyne, *Excurs.* xix., ad *Æn.* i.) The story of Memnon is variously told by the later writers, all agreeing that he came to the aid of Priam with a force of Ethiopians; and was slain by Achilles. (*Dict.* iv. 4, vi. 10; *Quint. Smyrn.* ii. 30, *et passim*; *Tzetz. Posthom.* 235; *Paus.* x. 31; *Apollod.* iii. 12, sect. 4; *Diod. Sic.* ii. 22, iv. 75, &c.) Some call him a leader of Indians as well as Ethiopians, or consider the two identical. Those additions which make Memnon to have been sent by Teutamus, a king of Assyria, whose vassal his father was, and which connect him with Susa, probably result from an attempt to gain a synchronism of Greek and Assyrian history. Any direct endeavours to find a place for Memnon in Assyrian and Egyptian history, which might at first sight be ascribed to native sources, are especially important with reference to his story and his connection with various places and monuments. In the cases of both countries they appear to be wholly of Greek origin, or at least of an origin external to the nations to whose histories they have been attached. The fragments of Assyrian history preserved by ancient writers contain no direct mention of Memnon; but in one list there is an evident reference to him. In it occurs the name of Teutamus, with in one version the addition, in a very corrupt form, that in his time Troy was taken by the Greeks. (Cory's *Ancient Fragments*, 2d ed., p. 77.) The character of the whole list, which consists of Assyrian, Persian, and Greek names, strung together so as to fill up a certain period, makes any further examination needless. There does not seem to be any other mention of Memnon which could at the first view be even conjecturally assigned to an oriental source. The supposed Egyptian reference to Memnon of the same kind is equally unauthoritative, although found in a far different document. The list of dynasties, epitomized from the lost work of Manetho, the Egyptian historian, contains, under some reigns, historical observations which are not always original. (See MANETHO.) Among these notices is one relating to Memnon. It is said of Amenôphis, the seventh or eighth sovereign of the eighteenth dynasty, the Amenoph III. of the monuments, that he is considered to be Memnon and the speaking stone. (*Anc. Frag.*, p. 116, 117.) It was a statue of this king that was celebrated as the Vocal Memnon; but there is strong reason to suppose that it did not become famous until long after Manetho's time; and the Egyptians, as appears from the inscriptions of visitors on the statue, took no interest in the vocal phenomenon. It is reasonable, therefore, to regard the notice in the lists, like others of a similar character, as not virtually Egyptian, and added by an epitomizer or chronologer. The examination of the inscriptions of the statue has however shown, as positively as can be on evidence of this kind, that the connection of Memnon with Egypt was of Greek origin. Thus the old Greek tradition or myth is our only authority. If we carefully consider it, we can scarcely do wrong in concluding Memnon to be a mythological personage. Whatever view we take of the Trojan war itself; whether we consider it, with some, as purely mythological; or, with others, as having a vague historical basis; or, again, with others, as having a sure historical basis; we must be ready to admit that most of the heroes are mythical. If we suppose, as seems most reasonable, some of those from whom descent was claimed by contemporaries of Homer to be personages whose memory was preserved in tradition, we may fairly argue the reality of not a few Greek heroes; but we could scarcely apply this argument to the case of foreigners who were not even Trojans. The Greek form of Memnon's name also, like Agamemnon, is somewhat against his reality, although it should be noted that its root is found in the Semitic languages and in Egyptian (see HIEROGLYPHICS, vol. xi., p. 372); so that it might be similar to an original name both in sound and in signification. If, however, we hold that there was, at about the time to which the Trojan war has been usually assigned, a great struggle between the Greeks and the Asiatics in the Troad, we find strong reason for supposing some such expedition from the East as that of Memnon. The progress of modern research is tending to show the truth of the broad outlines of many such traditions, as it indicates the general state of the countries to which they refer. The power of the Assyrian empire about this period was so great, that it is scarcely possible that a war of any length and importance could have been waged on the western coast of Asia Minor without its interference; and Memnon—who in the older form of the story is always an eastern Ethiopian, as the son of Aurora should be, and not a western—may with his forces be taken to represent some such aid from Assyria. It was not unnatural, that as in subsequent times Egyptian sites were in some manner connected with Memnon by Greek travellers or their guides, he should have been associated by later authors with the western Ethiopians also,—unless, indeed, this last idea gave rise to a search for Memnonian remains in Egypt. The twofold geographical division of the Ethiopians was known to Homer and Herodotus, is indicated in the Scriptures, and has been, last of all, confirmed by the cuneiform inscriptions, and, we may venture to say, by ethnology also. It is worthy of remark, that the chief individual identified in Egypt with Memnon appears in his race to have singularly corresponded to the Memnon of the later writers, since there is reason to believe him to have been sprung from the eastern as well as the western Ethiopians; but this agreement can hardly be considered as more than fortuitous.

Although tombs of Memnon, and structures or places called after him, were shown in various countries, there are but two which can be considered of high importance,—the Acropolis of Susa, called the *Memnonium* or *Memnonia*, and the great western suburb of Egyptian Thebes, bearing the latter name. The former town is called by Herodotus Memnonian (v. 54), doubtless from the Acropolis, which was probably its most ancient part. Pausanias alludes to the thickness of its walls (lib. iv., c. xxxi., § 5). The suburb of Egyptian Thebes called *Memnonia* (τὰ Μεμνόνεια) is generally held to have included all the buildings on the western bank of the river; but Sir Gardner Wilkinson considers it to have been only a part of Pathyris, the "Libyan suburb." (*Modern Egypt and Thebes*, vol. ii., p. 137.) It must have been, however, the most important quarter. Its name can scarcely be said to be of Greek origin, for it is as old as the time of Ptolemy Physcon, when a Greek identification of its edifices, or of the famous vocal statue, would not have been able to give a name to part of a town so thoroughly Egyptian as Thebes, though it could easily originate a corruption. We have only to remember the manner in which purely native names by a slight change were connected with Greek mythology or tradition, as in the cases of Canopus and Antæopolis, to see how easily a name resembling Memnonia would have been converted by the Greeks into that word.

The Vocal Memnon is the northernmost of two seated colossi, representing Amenoph III., placed in the approach to a temple now utterly ruined, in the midst of western Thebes. The temple appears to have been wholly raised by the same sovereign; and if any structure were specially called by the Greeks a Memnonium, it must have been this; although it is more probable that all the temples, or at least the larger ones, in the quarter bore this name. It is a common error to call the temple of Rameses II., or the Rameseum of El-Kurneh, the Memnonium. The height of each of the two colossi is about 47 feet, and they rest upon pedestals about 12 feet high. Greek and Latin inscriptions on the Vocal Memnon, chiefly on the legs, attest that visitors have heard the voice of Memnon, and paid this work of reverence to him, for they are *proscynemas*. The inscriptions record the visits of Hadrian and the Empress Sabina and their suite, of eight governors of Egypt, and several other persons holding office. The number of inscriptions known is seventy-two, of which thirty-five bear dates. The earliest is of the ninth year of Nero; the latest of the reign of Septimius Severus. We learn from them, and the concurrent testimony of ancient writers, that the vocal phenomenon did not occur, or at least did not attract attention, until after the Roman conquest, that apparently it ceased at the time of Severus, and that it was an object of veneration to the Greeks and Romans, and not to the Egyptians. At this time the statue was broken in two; and it was from the portion remaining in its place, the lower half, that the sound seemed to come. Some of the inscriptions agree with Pausanias in ascribing the overthrow of the statue to Cambyses; but Strabo heard that it had fallen through an earthquake. The former opinion seems on the whole the more reasonable, since it has the weightier evidence on its side, and because such a convulsion as would suffice to break a monolithic statue would be far more violent than any recorded to have happened in Egypt. Yet there are traces of the effects of earthquakes in that country, and probably at Thebes; and it is not to be forgotten that Eusebius relates that one which occurred B.C. 27 destroyed this town. It is to this earthquake that Letronne ascribes the overthrow of the statue. The upper part was subsequently restored, and it is not improbable that this was done by order of the Emperor Septimius Severus, as the same savant conjectures. The sound is said to have resembled the twanging of a harp-string or the striking of brass. The ancient writers who speak of the time of its occurrence say that it was at sunrise, when the sun's rays first struck the statue; but the inscriptions show that it did not always occur until some time, often a considerable time, after sunrise. As to the cause of the sound opinions are much divided, and mainly with respect to its genuineness. Sir Gardner Wilkinson argues it to have been an imposture, and cites the remarkable fact that one of the stones of which the upper part is formed, just above the main fracture, when struck gives a metallic sound. (*Mod. Egypt and Thebes*, vol. ii., p. 160-162.) M. Letronne considers that the sound cannot have been the result of an imposture, and shows that similar sounds have been heard to proceed from stones under the influence of the sun's says. Several of the writers of the great *Description de l'Egypte* frequently heard such a sound, always shortly after sunrise, apparently issuing from one of the roof-stones of the granite sanctuary of the temple of El-Karnak. Mr Lane also states (in his MS. journal) that in the neighbouring temple, called the Rameseum of El-Kurneh, he heard for several successive days "a single, distinct, musical sound, like that produced by a harp-string, evidently proceeding from some stone above him." This occurred shortly after noon. He supposes that at this time the stone became exposed to the sun, and suddenly expanding by the increase of temperature, produced the sound. There is therefore a possible explanation of the voice of Memnon, which, if an imposture, could scarcely have been successfully maintained in such a position for two centuries. It is easy to understand how the Greeks, finding a statue which gave forth a musical sound when touched by the solar rays, in a place called Memnonia, or having a name nearly resembling this, supposed it to represent Memnon, who thus saluted his mother; and the Egyptian priests would have readily encouraged the delusion; or they may have even originated the idea, to impose upon the Greeks. —In these observations on the Vocal Memnon we have mainly followed M. Letronne's *Statue Vocale de Memnon*, an essay which, notwithstanding some faults of strained reasoning, is the most learned and satisfactory one that has been written on this curious subject.

2. *Memnon* the Rhodian, a Greek commander in the Persian service. At the time of Alexander's invasion he governed the west coast of Asia Minor. The battle of the Granicus was fought against his advice, and he was afterwards invested with the entire command of the west of Asia. He defended Halicarnassus with great skill and obstinacy, and when it was no longer tenable crossed to Cos. Having large supplies of money from Darius, he collected a mercenary force, and projected the invasion of Greece. After several successes in the subjugation of the islands, he

died at Mytilene B.C. 333. He appears to have been the only general in the Persian service capable of offering any serious resistance to Alexander.

3. *Memnon*, a governor of Thrace, who made a revolt while Alexander was in the East, which was soon suppressed by Antipater.

4. *Memnon*, a Greek historian of the Roman period, probably of the first or second century of the Christian era. He wrote a history of the town of Heraclea in Pontus, part of which Photius has preserved in a somewhat copious abstract. His historical accuracy is much to be commended, but he shows great ignorance of geography. These remains are given in the *Fragmenta Historicorum Græcorum* (Didot), vol. iii., pp. 525-558. The best separate edition is that of J. Conr. Orelli, Leips. 1816. (R. S. P.)

MEMPHIS, an ancient city of Egypt, the site of which is on the W. bank of the Nile, about 10 miles S. of Cairo. Its name, in Egyptian, was *Men-nufr*, signifying the "good abode," or, as some think, the "abode of the good one," or *Osiris*. In Hebrew it was called *Moph* or *Noph*. The sacred name was *Ptah-ee*, "the abode of Phthah," or Vulcan, its chief god. The foundation of Memphis is ascribed to Mênês, the first king of Egypt, who reigned about B.C. 2700. On the division of the kingdom not long afterwards, it became the capital of successive Memphite dynasties, which appear to have lasted, with one considerable break, through about a thousand years. Under the Fourth Dynasty, which was the second Memphite one, the most famous of the pyramids near the city were raised. During this long period it seems to have been the most important city of Egypt. When the whole country was united under one Theban sovereign (B.C. cir. 1525), Memphis became the capital of Lower Egypt, and probably had a larger population than the kingly residence, Thebes. Under the Lower Egyptian dynasties that ruled after the Theban line Memphis recovered much of its importance, and was virtually the chief town until the foundation of Alexandria. After this it was the native capital for some time, and second only to the new city. It was finally ruined by the foundation of El-Fustát, upon the opposite bank, by the Arab conquerors.

The most important edifices and monuments of Memphis were the temple of Phthah, the Serapeum, the burial-place of the bulls Apis, and the pyramids. The first of these was the chief temple of the place; and successive kings from the earliest times made additions to it. Its site is marked by but scanty remains, for it has been used as a quarry, like the other Memphite monuments, by the Mohammedan inhabitants of the successive Arab capitals. The ruins of the Serapeum, and the vast subterranean sepulchre of the bulls Apis in connection with it, have been lately discovered by M. Mariette. The pyramids, which were the tombs of kings, and apparently of other royal personages also, extend along the edge of the desert behind Memphis for several miles N. and S. Around them are the tombs of subjects. (For further information see the article EGYPT.) (R. S. P.)

MEMPHIS, a town in the state of Tennessee, Shelby county, North America, pleasantly situated on the Mississippi, just below its confluence with the Wolf River, 420 miles below St Louis, and 209 miles W.S.W. of Nashville. The town is built on a bold promontory, 30 feet above the river; while below, a bed of sandstone running into the river forms a convenient landing-place. The town has a large esplanade in front, and many very handsome buildings, of which the chief are,—six or seven churches, an academy, a medical college, two banks, &c. Memphis is a place of great trade and growing importance; while shipbuilding and manufactures of iron, cotton, and ropes, are also carried on. Pop. (1850) 8841; (1853) about 12,000.

MENA, JUAN DE, a Castilian poet of considerable merit, was born at Cordova about 1411. He was early left an orphan; and at the age of twenty-three, as Romero naïvely informs us, he first gave himself to "the sweet labour of good learning," pursuing a regular course of study at Salamanca and Rome. On his return he was made a governor of his native city; and his learning and skill as a poet soon gained for him admittance at the court of Juan II., where he secured the friendship of the veteran soldier and elegant poet the Marquis of Santillana, and afterwards received the appointment of Latin secretary to the king and historiographer of Castile. He became ultimately a kind of poet-laureate. If a battle was won, Juan de Mena had to celebrate the victory in verse; if a pacification took place between the king and his son, the poet recorded the restoration of harmony in appropriate song; and if the Constable de Luna received a slight wound, Juan was ready with his *quintillas* to soothe the pain. He found friends also among eminent personages in Portugal. The Infante Don Pedro, himself a versifier of some note, made the acquaintance of Juan while in Spain, and on his return to Lisbon addressed him in tolerable verse, and afterwards wrote a skilful imitation of the Spanish poet's *El Laberinto*. De Mena died suddenly in 1456 at Torrelaguna, where Santillana, his fast friend and patron, wrote his epitaph, and erected a beautiful monument to his memory, which stands to the present day. Some of De Mena's shorter effusions are extremely pleasant and amusing; but the greater number of his minor poems are full of affectation and fashionable conceits. His poem of the *Seven Deadly Sins*, although of grave pretensions, is but a dull allegory full of pedantry and false metaphysics. The *Coronation*, written in honour of his noble patron the Marquis of Santillana, is a sort of light parody on the *Divina Comedia* of Dante, and while an improvement on his previous poem, is nevertheless overloaded with unprofitable learning. The descriptive passages, however, are often admirable, and the versification is smooth and flowing. His long poem, the *Labyrinth*, or *The Three Hundred*, the composition of which was spread over a large portion of his life, was designed to teach, by vision and allegory, the duties and destinies of man, and is written in direct imitation of Dante's great work. Of the historical portraits introduced into the poem, the best are those of the poet's countrymen and contemporaries. Passing by the courtly flattery paid to the king and the constable, there are occasionally lines of uncommon power and tenderness, recording the premature fate of some noble Spaniard, such as the Count de Niebla. This poem met with great admiration at court; it was submitted to his majesty piecemeal as it was composed, and had the honour to receive a correction from the royal pen. Some have accorded to De Mena the title of the "Spanish Ennius," a distinction which may be considered generous, but can hardly be called just. He has always had a respectable position with his countrymen, if he cannot be considered absolutely popular. The most elaborate editions of his works are those of the learned Hernan Nuñez de Guzman, with a comment, 1499; and of the eminent scholar, Francisco Sanchez de las Brozas, commonly called El Brocense, also with a *glosa* or comment, 1582. These editions have been frequently reprinted. The principal materials for the Life of Juan de Mena are to be found in the verses of Francisco Romero, in the *Epicedio en la Muerte del Maestro Hernan Nuñez*, 1578, at the end of the *Refranes de Hernan Nuñez*. (Ticknor's *Hist. of Spanish Lit.*, vol. i., 1849.)

MÉNAGE, GILLES, "the Varron," according to Bayle, "of the seventeenth century," was the son of the Avocat du Roi, and was born at Angers on the 15th August 1613. A tenacious memory and a keen desire for knowledge carried him speedily through his course of studies, and at the early age of nineteen he assumed, in accordance with the wishes of his father, the advocate's gown. But his early developed bias towards literature was irrepressible; and after practising at the bar in Angers, Paris, and Poitiers, he abandoned the profession in disgust, and entered the church. Soon afterwards his promotion to some sinecure benefices enabled him to devote all his time to his favourite pursuit. His varied accomplishments introduced him to the most select literary society, and in no long time he was received into the family of Cardinal de Retz. But Ménage was too self-willed for a *protégé*. His caustic wit and sarcastic humour were exercised without any compunction on the political creatures of the cardinal, and his unwillingness to soothe the vanity he had wounded aggravated the offensiveness of his conduct. Accordingly, he was forced to leave the house of his patron after a few years. He retired to a dwelling of his own in the cloister of Nôtre Dame, and there he began to gather around him on Wednesday evenings those literary assemblies which he called *Mercuriales*. About this time he might have been admitted into the French Academy had he not preferred to ridicule the dictionary of that body in his *Requête des Dictionnaires*. The latter part of Ménage's life was embittered by the attacks of those authors whom his ill-tempered satire had provoked. He died on the 23d July 1692. So unrelenting were his enemies that they made even his death a subject for their satirical wit. Of the voluminous works of Ménage the following are the most important:—*Dictionnaire Etymologique*, or *Orignes de la Langue Française*, fol., 1694, and 2 vols. fol., Paris, 1750; *Origini della Lingua Italiana*, fol., Geneva, 1685; an edition of Diogenes Laertius; *Anti-Baillet*, 8vo, Paris, 1685; *Juris Civilis Amœnitates*, 8vo, Paris, 1667; and *Poemata Latina, Gallica, Græca, et Italica*, 12mo, Amsterdam, 1687. After his death *Ménagiana* was published in 2 vols. in 1693–94, and afterwards in 4 vols. in 1715.

MENAI STRAIT, an arm of the sea in North Wales, separating the island of Anglesea from the county of Carnarvon, and extending from N.E. to S.W. to a length of about 14 miles, with a breadth varying from 200 yards to 2 miles. The navigation of this strait was formerly impeded by dangerous rocks, many of which, however, have been removed, and ships, especially those with a tonnage of less than 100 tons, now pass through in safety. The Menai Strait is chiefly remarkable for the two bridges by which it is spanned. The Menai Suspension Bridge, by Telford, was begun in 1819 and opened in 1826. It is of a very elegant form, and is supported by two piers, the distance between which is 550 feet, and the whole roadway, which is carried over four arches on one side and three on the other, has a length of 1000 feet, and a breadth of 30 feet. The height of the bridge above the level of high-water is 100 feet, and the total suspending power of the bridge, exclusive of its own weight, is calculated at 1527 tons. The cost of the erection was L.120,000. The Britannia Tubular Bridge is a still more wonderful erection. It was built for the Chester and Holyhead Railway by Stephenson, and was completed in 1850, after having been in the course of construction for four years. Owing to the necessity that it should be 100 feet above the water throughout, it was impossible to construct the bridge in the usual way with arches; and on account of the vibration to which it would be liable, the suspension principle was not employed. It was therefore constructed of tubular beams of iron, by means of which the greatest amount of strength with the least weight was obtained. These beams form eight large tubes, which rest upon three towers in the sea and an abutment on the land on each side. The whole length of the roadway is 1841 feet, and its height above high-water is 101 feet, while the total height of the central tower is 230 feet. The weight of all the tubes is nearly 11,000 tons, being more than that of four line-of-battle ships fully equipped; and the cost of the whole was L.621,865. (See IRON BRIDGES, vol. xii., p. 607.)

MENAM, or MEINAM, a river of Siam, rises in the Chinese province of Yun-nan, flows southwards through the centre of Siam, and after traversing for about 800 miles a rich and well-cultivated country, discharges itself into the Gulf of Siam. It is the most important river in Siam, and its name signifies, in the language of the country, "mother of waters." The Menam is navigable as far up as Chiang-mai, in the Laos country, but its course is frequently interrupted by rapids and falls. At certain seasons it overflows its banks,—a circumstance which contributes greatly to the fertility of the neighbouring land, and to the facility of communication between different parts. On the banks of the Menam stand the ruins of Ayuthia, the ancient capital, and the city of Bankok, which is the chief town.

MENANDER, the most eminent poet of the new comedy in Greece, was the son of Diopeithes and Hegesistrate, and belonged to the *demus* of Cephissia. It is generally agreed that he was born in 342 B.C., the same year in which his father commanded the Athenian forces in the Hellespont against Philip of Macedon. He had the advantage of receiving his education from his paternal uncle, Alexis the comic poet, and Theophrastus the philosopher. An intimate friendship which he formed at an early age with Epicurus may account for much of the tone of his subsequent works. Menander's first play, entitled 'Οργή, was exhibited in his twenty-first year, and gained a prize. Not so successful were the majority of his after efforts. His genius scorned to stoop to the gross jesting that was so palatable to the mob; and accordingly, out of more than a hundred comedies which he composed, only eight won the palm. Yet the popular sentence was reversed by a band of select admirers, including Ptolemy, the first Greek King of Egypt, and Demetrius Phalereus. So intimate, indeed, was he with the latter, that on the expulsion of that eminent statesman from Athens, he with difficulty escaped being put to death. Menander had an estate at Piræus; and it is said that he was drowned while swimming in the harbour of that place in 291 B.C. The Athenians erected a tomb to his memory not far from that of Euripides. His statue was also placed in the theatre; an honour, however, which was conferred upon too many to be of much value.

Only some fragments of Menander's numerous plays remain. They were lately printed by Meineke in the fourth volume of his *Fragmenta Comicorum Græcorum*, 8vo, Berlin, 1841. They were also published, with a Latin version by Dübner, as an appendix to the *Aristophanes* of Didot's *Bibliotheca Scriptorum Græcorum*, 8vo, Paris, 1840. Many of them have been translated into English by Cumberland in the *Observer*.

Menander was the first that established the superiority of the new comedy over the old. Clearly perceiving that every form of the drama ought to be a representation of nature, he abolished the use of the chorus, and changed comedy from a satire upon persons into a description of manners. He subdued the boisterous mirth of the old comedy, and by introducing occasionally the deep earnestness of tragedy, rendered his incidents at once more impressive and more life-like. So exquisitely faithful, indeed, were his delineations from nature, that Aristophanes the grammarian exclaimed in quaint admiration, "O Menander! O Life! which of you two copied from the other?" The estimation in which Menander was held by the ancients is indicated by the number of his imitators. Among his countrymen, Alciphron and Lucian borrowed from him. Among the Romans the best writers of comedy were often the closest imitators of Menander. Cæcilius stole from him many of the titles, and probably a great part of the substance, of his plays. Afranius is accused by Horace, in the language of allegory, of wearing a gown that once fitted Menander. So openly and extensively did Terence plagiarize from the famous Greek comic poet, that Cæsar addresses him as "Dimidiate

Menander." The following eulogy of Menander is given by Quinctilian (x. l.):—"He has delineated the picture of human life most accurately; his invention is fruitful, his eloquence powerful, his characters, passions, and manners proper and natural."

Menander was handsome in person, polished in his manners, and self-possessed in his bearing. His scrupulous attention to elegance and effect transformed him sometimes into a coxcomb. He was wont to come into his patron's presence with a mincing gait and languid air, redolent of perfumes, and clad in a nicely adjusted robe; yet the native good-humour of his countenance could not be concealed by his affectation, nor driven away by his repeated defeats at the public theatre. Meeting on one occasion his most formidable competitor, he said to him, "Pray, Philemon, do you not blush when you carry off the palm from me?" That the morality of Menander was not below that of his own age is shown by the fact that his plays were universally read, were prescribed by teachers to their pupils, and were represented at private banquets. (See the dissertation on the life of Menander affixed to Meineke's *Menandri et Philemonis Reliquiæ*, 8vo, Berlin, 1823.)

MENASSEH, Ben Israel, a celebrated rabbi, the son of a rich merchant, was born in Spain about 1604. At an early age he fled along with his father from the terrors of the Inquisition, and repaired to Holland. In his eighteenth year he succeeded his teacher Isaac Uziel as expounder of the Talmud in the synagogue at Amsterdam. His great work, *Conciliador nel Pentateucho*, Amsterdam, 1632, introduced him to the favourable notice of the learned among both Jews and Christians. In the following year a Latin translation, by Dionysius Vossius, appeared under the title of *Conciliator, sive de Convenientia Locorum S. Scripturæ quæ pugnare esse videntur.* About 1639 the seizure of his property by the Spanish Inquisition drove him to settle at Basle as a merchant. Induced soon afterwards to visit England in the hope of obtaining more privileges for his nation, Menasseh was favourably received and entertained by Cromwell. He died at Amsterdam about 1659. The rest of Menasseh's important works are,—an edition of the Hebrew Bible, without points, in 2 vols. 4to, Amsterdam, 1635; an edition of the Talmud, with notes, 8vo, Amsterdam, 1633; *De Resurrectione Mortuorum libri* iii., 8vo, Amsterdam, 1636; *De Fragilitate Humana ex Lapsu Adami, deque Divino Auxilio*, Amsterdam, 1642; *Spes Israelis*, 12mo, Amsterdam, 1650; and *A Defence of the Jews in England*, London, 1656. The *Conciliador* has been translated into English, by E. H. Lindo, in 2 vols. 8vo, London, 1842. Dr Thomas Pococke has written the Life of Menasseh in English.

MENDE, a town of France, capital of an arrondissement of the same name in the department of Lozère, is pleasantly situated on the left bank of the Lot, 75 miles N.W. of Avignon. The town, which is nearly triangular in shape, is ill built, with narrow, crooked streets. The principal buildings are the cathedral, a Gothic edifice, with two spires; and the old episcopal palace, which is now the prefecture. The town has also a library and a picture gallery. In the vicinity is the hermitage of St Privat; and the surrounding country is studded with country houses. The manufacture of coarse woollen stuffs, which bear the name of the town, is extensively carried on here, and these articles are exported to Germany, Spain, and Italy. The town was fortified in 1151 by Adalbert, Bishop of Gévandan, and the ramparts now form a fine walk. This town suffered much in the civil wars of the Reformation, and was taken no less than seven times. Pop. (1851) 6345.

MENDELSSOHN, Bartholdy Felix, one of the most distinguished musicians of the nineteenth century, was born at Hamburg on the 3d of February 1809. His grandfather was the celebrated Moses Mendelssohn, a Jewish philosopher and writer on various subjects, and, among these, on the æsthetics of music. His father was a wealthy merchant of the Jewish persuasion at Berlin, who spared no expense on the literary as well as musical education of his son Felix. His mother, an accomplished woman, gave him his first lessons in music. During a visit to Paris, he and his sister received lessons on the pianoforte from Madame Bigot; and on his return to Berlin he was placed under Berger the pianist and Zelter the teacher of harmony and counterpoint. He received some lessons from Hummel; and in a few years became a first-rate pianist and an excellent organist, besides acquiring a practical knowledge of the violin, and a familiarity with the powers and uses of orchestral instruments. In 1821 he had become an excellent pianist, and had learned to improvise with great facility upon any musical theme given to him; while his retentive memory enabled him to play without book most of the finest classical pianoforte compositions. Being really in one sense an amateur musician, from the wealthy condition of his father, he was at full liberty to develop his musical powers in any form that he might choose. In that respect he was not like Handel, Haydn, Mozart, Beethoven, and others, who, as young prodigies of musical talent, had nevertheless to make their bread by their art, and to endeavour to consult the taste of the public. Probably this superiority of social condition may have influenced his feelings and the style of his musical compositions. Certainly he seems in general to have cared little for the production of that flowing and impressive melody which forms so great a charm in the works of the great composers just named, and to have devoted his attention rather to the effects of instrumentation, and to the resources of harmony, modulation, and counterpoint. In his fifteenth year he published two quartets for pianoforte, violin, viola, and violoncello. Next, a grand sonata for pianoforte and violin, and a third quartet. In 1827 he brought out at Berlin a comic opera, *Die Hochzeit des Camacho*, which did not succeed, and was withdrawn. This disappointment seems to have disgusted him for life with opera-writing. A copy of that opera, arranged for pianoforte, &c., was published at Berlin. In 1829 Mendelssohn visited London, and the writer of this article then heard him perform, at a rehearsal in the Philharmonic Society's rooms, a double concerto with Moscheles in a style that excited great admiration, and witnessed his conducting of his Overture to *A Midsummer Night's Dream*, with a minute attention to the details of orchestral effect which seemed quite new to the performers, and not a little annoying to their self-love; for Mendelssohn frequently stopped them, and made them repeat the passages over and over until he was satisfied. But the lessons that he then and afterwards gave them were not forgotten: they were laid to heart, and in a very few years rendered the London Philharmonic orchestra one of the best in Europe. From London Mendelssohn went to Edinburgh with his friend the Chevalier Neukomm, and after a short residence there, visited some of the most remarkable scenery of Scotland. His visit to Staffa suggested his Overture to *The Cave of Fingal.* He afterwards went to Paris, and performed there; and then visited Italy, where he remained about four years. After his return to Berlin he was engaged in a music-directorship at Dusseldorf, which he resigned in 1836, in consequence of irreconcilable dissensions which arose between him and the artists and amateurs. It was there that he composed and produced his Oratorio of *St Paul.* In that year he married at Frankfort. In 1837 he settled in Leipsic as director of the concerts; and the university conferred on him the title of Doctor. He was called to a court appointment at Berlin, but soon obtained leave to return to Leipsic, where he felt that he could serve his art better than at court. At Leipsic he composed most of his works; and by his unwearied exertions at last formed

Mendelssohn, Bartholdy Felix.

in that town a school of music, which is now one of the best in Europe. He was frequently called away from Leipsic to conduct performances of his own music, and several times revisited England, which, next to his own Germany, was the land he best loved. His last visit to England was in 1846, to conduct his *Elijah*, written for that year's Birmingham festival. Incessant labour at last affected his health, and rendered relaxation indispensable. He proceeded to Switzerland. In May 1846 he received news of the death of his sister, Madame Hensel, whom he tenderly loved. From this severe shock he never recovered. He endeavoured to divert his mind by making sketches of Swiss scenery,—for drawing and painting were among his many accomplishments,—but he felt that his bodily frame was decaying, and used to speak to his friends and relatives of his approaching death. Soon after his return to Leipsic he was attacked, on the 8th of October 1847, by a violent cerebral affection, which proved fatal on the 4th of November following. He left a widow and children to lament his premature death. His amiable manners, as well as his extraordinary accomplishments, endeared him to numerous friends, among whom he reckoned several in Great Britain. His domestic virtues are highly spoken of by all who knew him intimately. He was below the middle height, and delicately formed; his countenance handsome and intellectual, though somewhat effeminate. A good classical scholar, and well acquainted with modern languages, he possessed an accomplishment that is very rare among continental musicians—*i.e.*, he spoke and wrote English remarkably well. Though not absolutely endowed with musical genius, his musical talents were of the highest order. The dry and pedantic discipline of Zelter may have repressed the *estro* of his gifted young pupil, and such training left its impress for a long time upon the compositions of Mendelssohn. About that time also several German theoretical and æsthetical writers began to declaim against Italian melody, and to insist that in music harmony and modulation were all in all. The bad effects of this false doctrine are but too evident in the music of the new German school. Mendelssohn's early death prevented the full development of his powers of composition, for it is evident that his style was becoming year after year more free and melodious. His *St Paul*, his *Elijah*, and his Symphony in A, are proofs of this. Most of his earlier works show more of musical learning and calculation than of melodic inspiration. As he never was compelled to write for bread, he always wrote his best—always carefully and conscientiously. He was not easily satisfied with his own works. His knowledge of the art of musical composition was great; his musical reading very extensive, and his memory prodigious; his skill as a pianist and an organist almost unrivalled. Besides the works above named, Mendelssohn published the following compositions:—Overture, *Meerstille*, &c.; Overture, *Melusina;* Quintet in A for stringed instruments; two grand Quartets for stringed instruments; two Concertos for pianoforte, with orchestra; Octet for stringed instruments in E flat; three Quartets for pianoforte, violin, viola, and bass; grand Sonata for pianoforte and violin; Sonata for pianoforte and violoncello; seven characteristic pieces for pianoforte alone; Rondo for pianoforte; Sonata for pianoforte; Fantasia on an Irish air; three Fantasie for pianoforte; six melodies, without words (*Lieder ohne wörte*), for pianoforte alone; Concerto for the violin; religious Chorus, for four voices, *Aus tiefer Noth; Ave Maria*, for eight voices; religious Chorus for eight voices, *Mitten wir im Leben sind*; three Latin and German Motets, with organ accompaniment; the forty-second Psalm, with orchestra; grand Cantata for the anniversary festival of Albert Dürer; grand Cantata for the fête given by Alexander von Humboldt to the natural philosophers assembled at Berlin; three collections of songs for a single voice, with pianoforte; music to Göethe's *Walpurgis Nacht;* six Sonatas for the organ; music for *A Midsummer Night's Dream;* Choruses to *Antigone;* Symphonies for grand orchestra, in score. The above is an approximative list. Among his works that he left unpublished were,—Music to *Œdipus;* Choruses to Racine's *Athalie;* one act of his Opera of *Loreley;* songs for one voice and pianoforte, of which some of the best were written for Jenny Lind. (G. F. G.)

Mendelssohn, Moses.

Mendelssohn, *Moses*, was born in 1729 at Dessau, where his father was teacher in a Jewish school. Like all Jewish children he was from his infancy instructed in the Talmud, but the *Moreh Nevochim* ("Guide to the Wanderers") of Maimonides was the subject of his most passionate study. To the end of his days, in an impaired constitution and a distorted spine, he carried the marks of his youthful devotion to that book. In 1742 he came to Berlin, following in the footsteps of his instructor David Fränkel, and in the tide of all the aspiring Jewish youth of the day. Here, under Rabbi Israel, who had been expelled from Poland for his liberal studies, he added mathematical knowledge to the circle of his attainments; and under his teachers Emmerich, Keisch, and Solomon Gumpertz, he became acquainted with Latin and modern literature. His own philosophical genius led him to Locke, Leibnitz, and Wolf. At this time he was indebted to his countrymen Itzig, Marcus, and Bernhard for support. The last of these was a wealthy silk manufacturer, who, from being tutor to his children, ultimately raised him to partnership with himself in trade. No sooner did Mendelssohn rise above beggary than he inaugurated the grand mission of his life by aiming a blow at the bleak Talmudism of his nation. Along with Tobias Bock he prepared some short scientific tracts in Hebrew,—a step which called forth the rage and anathemas of the rabbis. In 1754 he became acquainted with Nicolai and Lessing, and began a friendship to which he owed much, and from which the critic, at least, derived profit in being furnished with the prototype of *Nathan the Wise.* From this time he devoted himself to the study of mental philosophy. His first work was the *Briefe über die Empfindungen* ("Letters on the Sensations"), and this was followed by a variety of short treatises, distinguished for acuteness more than for originality, but, above all, for the fine ethical tone which ran through them. He was engaged for many years in vindicating Lessing from the charge of Spinozism, which had been brought against him by Jacobi. His best known work, however, in this department of study is the *Phædon*, or "Dialogue of Socrates with his friends on the Immortality of the Soul." The characters and descriptive parts are taken from Plato, but the argument is new. Mendelssohn founds his doctrine, not on the simple texture of the soul, which renders it incapable of being resolved into component parts, but on its nature as exempting it from the ordinary laws of change. Kant, however, has shown that this is no argument against the soul's annihilation, and is not even satisfactory against the hypothesis of its gradual enfeeblement and ultimate decadence without any organic change. Of far greater historical importance were Mendelssohn's labours for the elevation of his Jewish countrymen. His translation of the Pentateuch into classic German, printed in Hebrew characters, introduced the literature of Germany into the Jewish schools of Poland, and ultimately extinguished the textbooks which had been conned for ages under the teaching of the Rebbe. Mendelssohn's position in the literary world was all the more startling that it was entirely novel, and whatever influence it gave him was sacredly devoted to the service of those of his own creed. His little book entitled *Jerusalem* appeared in 1783; and, along with two pamphlets written by the historian Dohm somewhat earlier, paved the way for the civil emancipation of the Jews. In these patriotic efforts he was seconded by many of his countrymen; and the work which he left unfinished was carried out by Hartwig Wesseley, Izaak Euchel, and David Friedländer. In the internal reform of the synagogue, however, he had no share. That was the second harvest of his labours, and one which, in the strictness of his own religious life, he did not anticipate.

Mendelssohn's literary labours were frequently interrupted by attacks of sickness. His constitution, shattered in early youth, received a new shock from every paroxysm of mental activity. Lavater's attempt to win him to Christianity prostrated him in a long and painful illness; and, in his zeal to defend his friend Lessing from the stigma of Spinozism, he so overtasked his energies as to bring on a fever, which terminated his existence in 1786. His works have been collected and published, along with a biography, at Vienna in 1838. A translation of the *Phædon* into English appeared in the same year.

MENDEZ PINTO, Ferdinand, was born at Montemor-o-velho in Portugal, and was at first servant to a Portuguese gentleman. In expectation of making a fortune, he embarked for India in the year 1537; but his vessel being taken by the Turks on his passage out, he was carried to Mokha, and sold to a Greek renegado, and afterwards to a Jew, in whose possession he continued till he was redeemed by the governor of Ormus, who procured him an opportunity of proceeding to India, agreeably to his original design. During a residence of twenty-one years in that country he was an eye-witness of many important transactions, and experienced many singular adventures. He returned in 1558 to Portugal, where he enjoyed the reward of his labours, after having been thirteen times a slave and sixteen times sold. A very curious account of his travels was written by himself, and published in Lisbon in 1614, folio. This work was translated into French by Bernard Figuier, a Portuguese gentleman, and printed at Paris in 1654, 4to. It is written in a very interesting manner, and in a style more elegant than might have been expected from a man whose whole life had been spent in the camp and in slavery. It relates with much credulity a great variety of particulars relating to the geography, history, and manners of the inhabitants of China, Japan, Pegu, Siam, Achem, Java, and other countries.

MENDICANTS, or Begging Friars, a religious order, appear in ecclesiastical history in the thirteenth century, at a time when the older castes of monks had lapsed into luxury and indolence, and were neglecting the instruction of the people. The men selected for this new society were well versed in the truths of the gospel, and were full of piety and holy zeal. Utterly destitute of all fixed revenues and possessions, they were forced to face every kind of hardship and self-denial. They were found in every country, under every variety of climate, travelling from village to village on their mission of love, suffering the ridicule of the scoffer and the persecution of the jealous ecclesiastic, toiling at times in the fields to earn a shelter for the night, receiving with cheerfulness the smallest crust that poverty could spare, and preaching continually, both by their lives and by their words, the healing truths of the gospel. In no long time their self-denying humanity and spotless character recommended religion to all classes of the laity, and requickened the dying influence of the church. Accordingly, Innocent III. thought it his duty to increase the respectability and usefulness of the Mendicants by releasing them from the jurisdiction of the bishops, and by rendering them responsible to the Roman see alone. The example of this pope was followed by several of his successors, and in consequence of this high patronage the number of the Mendicants continued to increase greatly. Of their many orders, the Franciscans and Dominicans speedily usurped all the zeal and influence of the others. Admitted, as confessors, into the confidence of all classes, they gradually stripped the clergy of all power and repute. At the same time their own reputation for zeal and piety procured their admission to the pulpits of pious bishops, and to the chairs of several universities. Young men of talent, brought up at their feet, were fascinated by their learning and eloquence, and caught their apostolic zeal. Their influence, therefore, spread rapidly through every country, until all Europe was filled with admiration and esteem for the Mendicants. In course of time they found their way into the highest civil offices, into the cabinets of kings, and the courts of popes. Becoming intoxicated with prosperity, they began to grow worldly-minded, to lend themselves as tools for papal extortion and ambition, to be puffed up with arrogance, to build spacious mansions, and to fare luxuriously. They even presumed to declare that they were the only real ministers of the gospel, that their indulgences were superior in efficacy to all others, and that they had supernatural intercourse with the saints, the Virgin Mary, and the Supreme Being. For some time a spirit of hatred against the Mendicants had become universally prevalent among the clergy, and it now broke forth into open hostility. Foremost among the assailants, William of St Amour, a doctor of the Sorbonne, attacked them in 1255 in a book entitled *The Perils of the Latter Times*. Several replies were written by Bonaventura, Thomas Aquinas, and other Mendicants; and in 1256 the controversy was stopped for the time by the decree of Pope Alexander IV., that William of St Amour should be banished, and that his book should be burned. The first check that the society experienced happened in 1272, when Gregory X., in a general council at Lyons, reduced their many orders to four, namely, the Dominicans, Franciscans, Carmelites, and Augustinians. Yet their influence did not decrease along with their number. Many cities about this time were divided into four parts, to afford distinctive spheres for the four sections of the Begging Friars. To receive the sacraments from a Mendicant priest, and to be buried in a Mendicant church, were the earnest wishes of every one. In the fourteenth century it was a common custom for those tottering on the brink of the grave to enter the ranks of this order, in the sure conviction that they were thus securing their salvation. Many on their deathbeds were comforted by the thought that the tattered Franciscan or Dominican garment in which they had ordered their dead limbs to be wound would save their souls at the last day. The Mendicants, however, during this century met with the most determined opposition from the clergy in all countries, and more especially from John de Polliac in France and John Wickliffe in England. This hostility continued until it was completely merged in the greater struggle of the Reformation. In the sixteenth century the position and influence of the Mendicants were usurped by the newly-instituted Society of Jesus.

MENDIP HILLS, a range of hills in England, county of Somerset, extending through the centre of the county from W. by N. to E. by S., having a length of about 25 miles, with an average breadth of 4 or 5, and rising in some places to the height of 1000 feet. The central ridge of these hills consists of old red sandstone, on the sloping sides of which strata of mountain limestone recline at various angles. These strata in several places entirely cover the sandstone, which is prominent in the most elevated parts of the range, forming four distinct ridges nearly equally distant from one another. The most remarkable features in the Mendip Hills are, a cavern called Woolsey Hole, and the Cheddar Cliffs, a long range of perpendicular crags overhanging a defile in the hills. The mineral productions are of considerable importance, consisting of lead, zinc, calamine, and coal. Part of the ground is cultivated, but the greater portion is used as pasturage for sheep.

MENDOZA, Diego Hurtado de, an eminent scholar, Mendoza, Diego Hurtado de.

statesman, and general of Spain, and grandson of the elegant Santillana, was born at Granada in 1503, of a family which, after the blood-royal, was perhaps the most illustrious in the kingdom. Lope de Vega turns aside in his *Arauco Domado* to boast that the name of the Mendozas had been nobly great for three-and-twenty generations. As Diego had five brothers older than himself, he was originally destined for the church; and after receiving his elementary education at home, he proceeded to Salamanca, where he studied Latin, Greek, philosophy, and canon and civil law. But Mendoza early showed a decided predilection for politics and elegant literature, and resolved accordingly to abandon the idea of becoming a churchman. During his residence at the university he produced his *Lazarillo de Tórmes*, a work of real genius, which appeared in 1553, and which has been a favourite in most modern languages down to the present day. It is a sort of comic romance, written in that *gusto picaresco*, or style of the rogues, so peculiar to Spain, and which, since the time of Mendoza, in the *Gil Blas* of Le Sage, and other works, has become famous throughout the world. Its object is to satirize all classes of society by assuming the character of a dexterous rogue, who, in his capacity of servant, gets behind the scenes and sees the actors in undress. It is written in a rich, bold, racy, Castilian style; and some of its sketches for freshness and spirit are unsurpassed in the whole range of prose works of fiction. The light, jovial, flexible audacity of the hero rendered him a great favourite with the grave Castilians. It nevertheless proved too much for the clergy, who issued an order for its expurgation, and solemnly denounced the anonymous author. Several continuations of the *Lazarillo de Tórmes*, by different writers, appeared afterwards, but none of them possessed much merit. Leaving the university, Mendoza joined the great Spanish armies in Italy; and while he entered with enthusiasm upon the duties of his new profession, he nevertheless found occasion, when the troops were unoccupied, to indulge his strong literary sympathies by listening to the lectures of the celebrated professors of Bologna, Padua, and Rome. The keen insight of Charles V. soon detected qualities in the young Spaniard which he resolved to turn to good account. Accordingly, in 1538 he appointed him his ambassador to Venice, afterwards made him military governor of Siena, and at a somewhat later date employed him to sustain the imperial interests at the famous Council of Trent. In 1547, while the council still sat, he was despatched by his royal master as a special plenipotentiary to Rome, to bring Pope Julius III. to a proper understanding. He boldly confronted and overawed his holiness in his own capital, and after rebuking him in open council, established himself in Italy, and governed that country for six years with great talent and firmness. But Charles, eager to conciliate the European powers before his abdication, began to alter his policy; and Mendoza, anxious for rest from his trying labours, returned to Spain in 1554 with a reputation for skill as an ambassador which afterwards passed into a proverb. The policy of Philip II. and the temper of Mendoza were little suited to one another, and the harsh tyranny of the emperor soon found means of ridding himself of the trusty ambassador. Having engaged in a passionate dispute with a courtier in the palace, the latter drew his dagger upon Mendoza, when the old warrior, who had lost little of the fire of his youth, though sixty-four years of age, wrested the weapon from the hands of his assailant, and flung it out of the balcony, throwing, as some add, the courtier after it. The spirited veteran could not be pardoned for such an affront to the royal dignity, and with his honours and gray hairs thick upon him, he was exiled from the court. The man, however, who in his college days had written *Lazarillo*, and who during the busiest negotiations had always found time to cultivate letters, was not likely to lament very deeply his apparent disgrace, if it brought him into closer intimacy with his old travelling companions, the *Amadis* and the *Celestina*. He accordingly found solace during his exile in writing poetry, collecting manuscripts, and in composing his *Guerra contra los Moriscos*, or "War against the Moors" (1568-1570). From Mendoza's long residence in Venice and Rome, and from his early and close intimacy with Boscan, he could hardly have escaped from the influence of the Italian school of poetry. Yet his verses, both in spirit and in form, are often characterized by a strong Spanish element; and while the reader meets obvious traces of his careful study of Horace and Pindar in his "Epistle to Boscan" and in his "Hymn to Espinosa," those beautiful productions are nevertheless full of the genuine old Castilian spirit. Some of his *letrillas* have a charming gaiety about them, and a light and idle humour, which savours much more of the author of *Lazarillo* than of the dignified ambassador. His history is written with great power and energy, in a style closely modelled after Sallust and Tacitus, displaying by turns more exuberance than the one, and nearly all the severity of the other This work is characterized by great impartiality,—not sparing even the author's own immediate relations who played an important part in these Moorish wars, and doing the hated enemies of his country so much generous justice that the book could not be published until 1610. Altogether it is perhaps the finest specimen of historical writing in the Spanish language. It was Mendoza's last work. In 1575 he obtained permission to return to Madrid, but died shortly after his arrival, at the advanced age of seventy-two.

Previous to his death Mendoza bequeathed the valuable classics and manuscripts he had collected with so much trouble in Italy, Greece, and Granada, to the Royal Library of the Escurial. The first complete edition of the *Guerra de Granada* is that of Montfort, with a Life of the author, Valencia, 1776, 4to. The only edition of his poems is that of Juan Diaz, Madrid, 1610, 4to. (See Life of Mendoza by N. Antonio in the *Bibliotheca Nova;* also Ticknor's *Hist. of Spanish Lit.*, vol. i., 1849.)

Mendoza, Inigo Lopez de.

Mendoza, *Iñigo Lopez de*, commonly known as the *Marques de Santillana*, the most elegant scholar and poet of the brilliant court of Juan II. of Spain, was born in 1398 of a highly distinguished family, which has sometimes claimed its origin from the Cid himself. His father, the Grand Admiral of Castile, having died while Iñigo was yet young, the family possessions, then the largest in the kingdom, were almost entirely wrested from the young heir by those bold and rapacious barons who then divided among themselves the resources as well as the power of the crown. But it did not accord with the temper of a Mendoza to submit to such wrong. As early as the age of eighteen we find that, partly by law and partly by force of arms, the young nobleman had succeeded in recovering his estates; and, as Oviedo quaintly informs us, "so began forthwith to be accounted much of a man." From this period we find him acting an important part in the stirring and wild times from which the reign of even the polished Juan II. was not free. If he suffered a defeat from the Navarrese, he gained enduring glory by his personal bravery and military skill; and attained to the rank of a marquis after the battle of Olmedo in 1445. While Santillana was frequently compelled to oppose the policy and conduct of the royal favourite, the constable Alvaro de Luna, he seems to have had but little share in the last scenes of the singular tragedy which found its catastrophe in the sacrifice of that able minister. From the fall of the constable till the death of Santillana in 1485, the marquis spent the greater part of his time in literary retirement.

During the confusion and violence of a turbulent age, the active part which he was called upon to take in state affairs never for a moment destroyed Santillana's earnest attachment to elegant literature. He remarked to Prince Henry, that "knowledge neither blunts the point of the lance nor weakens the arm that wields a knightly sword." His poetical works reflect distinctly the several influences of education and literary intercourse peculiar to his position and time. His works connect themselves more or less with the Provençal, Italian, and Spanish schools. The most graceful of all his poems is entirely in the Provençal manner, and yet for beauty and sweetness it has never been surpassed either in the Provençal or in the Spanish. It is called *Una Serranilla* (a little mountain song), and was composed on a little girl whom he found, when pursuing his military life, tending her father's flocks on the hills; and "the charming milk-maiden of sweet Finojosa" has borne some portion of her charms, even through the clumsy medium of translations, to many readers far beyond her native hills. The Marques has likewise the reputation of being the first to introduce the Italian sonnet into Spain; and which, since the time of Boscan, has gained for itself such a prominent place in the poetry of that country. The sonnets of Santillana possess little merit, however, except that of smooth and graceful versification. In his poem on the death of the Marques of Villena he imitates the opening of the *Inferno;* and his piece on the coronation of Jordi reminds the reader not unfrequently of the *Purgatorio* of the great Italian. His principal works, however, were chiefly in the manner then popular at the Spanish court; and many of them are so filled with conceits and affectation as to be almost destitute of value. Yet occasional passages are to be found in his *Ages of the World*, and *Fall and Death of the Constable*, which for strength, fluency, and grace, are worthy of the highest praise. But the most important, if not the most popular, of the poetical works of Santillana is the *Comedieta de Ponza*, founded on a great naval engagement near the island of Ponza in 1435, and approaching in its structure the form of a drama. It is, however, a sort of dream or vision, and as the poem was written shortly after the occurrence of the national calamity at Ponza, the principal figures are those of his own time. It is written in the old Italian octave stanza, in easy verse, prankt full of all manner of ancient learning, awkwardly introduced, and frequently displaying very bad taste. The most popular of all this nobleman's works is his collection of proverbs, made at the request of Juan II. for the instruction of Prince Henri. It is made up of a hundred sentences in rhyme of no poetical value, each containing one proverb. The Marques made another collection of unrhymed proverbs, gathered, as he phrases it, "from the lips of the old women in their chimney-corners." In these "short sentences drawn from long experience," as Cervantes calls them, Spain is in advance of all other countries. One of the most important documents we possess respecting the earlier Spanish literature is from the pen of this nobleman, and consists of a letter on the poetic art, written about 1455, and addressed to the young Constable of Portugal, who had asked the Marques for a copy of his poems.

The leading facts in the life of this remarkable man are to be gathered from the Chronicle of Juan II.; but a very excellent sketch of him is to be found in Pulgar's *Claros Varones*, c. iv.; and a clumsy but elaborate biography in Sanchez, *Poesias Anteriores*, vol. i. (Ticknor's *Hist. of Spanish Lit.*, vol. i., 1849).

MENDOZA, a province, town, and river of the Argentine Confederacy, South America. The province is bounded on the N. by that of San Juan, E. by San Luis, S. by an unsettled and desert region, and W. by Chili; and is about 150 miles in length, and nearly the same in breadth. The country for the most part is flat, except towards the W., where the Paramillo range of the Andes and some other branches diversify the form of the surface. In this part of the province are found several volcanoes. The principal rivers are the Mendoza, the Desaguadero, and the Tunuyan; and there are several lakes. The soil is for the most part sandy and sterile, but when well watered it is by no means unproductive. Corn, fruits, olives, and wine are the chief articles produced; and these, along with hides, soap, and tallow, constitute the most part of the export trade. Silver and copper are found here, as well as limestone, alum, slates, &c. Mendoza is an independent state, owing little subjection to the central government of the confederacy. The governor, who has the chief executive authority, is elected by the Junta or provincial assembly. The capital is Mendoza, situated at the foot of the Andes; Lat. 32. 53. S., Long. 69. 6. W. The city is neatly built and pleasantly situated; and from its dry, healthy climate, has obtained the name of the Montpellier of South America. The houses are for the most part low, and have gardens or orchards round them. Among its buildings are a handsome church and several convents. The public promenade, called the Alameda, which is about a mile long, under a fine avenue of poplars, is one of the best in South America. Pop. of the town, 12,000; of the province, 57,000.

The River Mendoza rises in the above province, near the volcano of Aconcagua; flows S.E. till about 10 miles from the town Mendoza, then turns to the N., and after a total course of 200 miles, falls into Lake Guanacache.

MENDRISO, a town of Switzerland, the capital of a district of the same name, in the canton of Tesino. It contains 1550 inhabitants, who are active and intelligent, and carry on much silk spinning. Being on the southern declivity of the Alps, the climate and productions resemble more those of Italy than the rest of Switzerland. It is only three miles from Lugarno, and nine from the lake of Como; and the vicinity yields excellent wheat, wine, tobacco, and silk. It consists chiefly of one long street, with a collegiate church, a Capuchin convent, and a nunnery of Ursulines.

MENEDEMUS, a Greek philosopher, was the son of Cleisthenes, a man of poor means, but of noble birth, and was born about 300 B.C. at Eretria, the capital of Eubœa. According to his biographer Diogenes Laertius, he was trained by his father to the trade of building and tent-making. But Athenæus represents him in his younger years as a miller, grinding in the mill all night, and studying philosophy during the day. A military appointment which he received at Megara gave him an opportunity of prosecuting his favourite study under Stilpo. He then repaired to Elis, and became a disciple of the Elean school of philosophy, which had recently been founded by Phædo. On his return to Eretria, Menedemus became a teacher of the doctrines he had learned at Elis. His character probably prevented an immediate rise in his new vocation, but was no doubt the means of his ultimate success. He was grave and taciturn, satirical, and disposed to rebuke every misdemeanour by a stinging sarcasm; fiery in temper, and declaiming frequently till be became black in the face. As he was indistinct in his elocution, we may infer that he was not very fascinating in his prelections. Yet his open and sterling disposition, and the satisfactory nature of his instructions, raised him to so great an eminence that the doctrines which he taught became identified with his school, and the Elean philosophy came to be called the Eretrian. In the same slow and sure manner did he rise to the highest civil offices. While Menedemus was thus acquiring fame and riches he was living in the same house with Asclepiades, the long-tried friend who had been his companion in his early hardships, and who was now admitted to be his companion in his good fortune. The avowed favour of Menedemus for Antigonus Gonatas led him to be suspected of a design to betray Eretria into that monarch's power. With the intention of vindicating his patriotism, he repaired to Antigonus, and besought him to restore his country to freedom; but meeting with a refusal, he starved himself to death, at the age of seventy-four.

As Menedemus did not commit his opinions to writing, the distinctive principles of the Eretrian school have been very partially and very vaguely ascertained. From Diogenes Laertius, however, we know that they resembled the school of Megara in the extreme and frivolous subtlety of their dialectics. Adopting also the Megaric doctrine, that existence was of necessity *simple*, and was therefore knowable only by direct cognition, they rejected all negative and hypothetical propositions. The same extreme generalization they employed in evolving a system of ethics. After taking an articulate distinction between the *good* and the *useful*, they proceeded to prove that all the virtues, though considered by ordinary thinking to be distinct from each other, are merely different forms of one idea, and are therefore essentially identical. They concluded their ethical system with asserting the complete identity of the *good* and the *true*.

MENEHOULD, Sainte, a town of France, capital of an arrondissement of the same name, in the department of Marne, is situated between two rocks on the Aisne, 26 miles E.N.E. of Châlons. The town is well and regularly built, and contains two fine squares, and a town-hall with an elegant front. There is also a tribunal of primary instance and a college; and the town has several fine promenades. The manufactures consist of hosiery, leather, &c.; and in the neighbourhood are several iron, glass, and china works. There is a considerable trade in wine, corn, wood, &c. The town is ancient. It was formerly fortified, and has been besieged and taken several times;—taken in 1436 by the English, and retaken by the Constable Richemont; besieged in vain by the Protestants in 1562, and by Charles II. of Lorraine in 1592; taken in 1652 by the Spaniards, and recovered in the next year by Louis XIV. Pop. (1851) 4137.

MENELAUS, King of Lacedæmon, was the son of Atreus, and brother of Agamemnon. He appeared among the numerous princely suitors for the hand of Helen, the beautiful daughter of Jupiter and Leda, and was successful. His wife, however, was afterwards carried off by Paris, the Trojan prince, and could not be reclaimed either by threats or by negotiations. All the Greek chiefs were accordingly summoned by Menelaus and Agamemnon to avenge this insult. A fleet of sixty ships was equipped, and a formidable expedition set sail against Troy. During the ten years' siege of that city Menelaus maintained the character of a sagacious counsellor and a lion-hearted warrior. On one occasion, according to Homer, he engaged with Paris in single combat before the two armies, dragged his adversary across the plain by the helmet, and would have avenged his own wrongs with his own hand, had not Venus interfered to save her favourite. He entered Troy in the wooden horse, and during the sack and massacre that ensued he recovered Helen, and carried her off. Returning homewards, Menelaus encountered a storm that wrecked one part of his fleet on the coast of Crete, and drove the other, which contained himself, to the coast of Egypt. He then wandered about uncertainly for eight years, driven by fortune to Phœnicia, Æthiopia, and Libya, and even to Japygia in Italy, and Eryx in Sicily. At length he arrived in Myccnæ at the very time when the Argives were threatening to stone Orestes and Electra for the murder of their mother Clytæmnestra. On the apotheosis of Castor and Pollux, the kingdom of Laconia was surrendered to Menelaus by his reputed father-in-law Tyndareus. It is related by Homer, that when Telemachus, wandering about in search of his father, arrived at Sparta, he found Menelaus and Helen enthroned in great magnificence in a lofty palace that blazed in splendour like the sun or moon. They were celebrating, amid a crowd of princely guests, the marriage of their son Megapenthes to a daughter of Alector, and of their daughter Hermione to Neoptolemus. On account of his relationship to Jove, Menelaus, according to Homer, was fated to be transported, along with his wife, to the Elysian Fields without ever tasting death. Their tomb, however, was wont to be shown at Therapne, not far from Sparta. (Hom. *Il.* and *Od.*)

MENES. See Egypt.

MENGS, Antony Raphael, a distinguished painter, was the son of a Danish artist of no high standing, and was born at Aussig in Bohemia on the 12th March 1728. From his sixth year he was forced by his father, on pain of severe chastisement, to study drawing for sixteen hours every day during both summer and winter. After receiving instructions in miniature and enamel painting, he was carried by his parent to Rome in 1741. On his arrival at Dresden in 1746 Mengs was appointed court painter to King Augustus. A second visit was paid to Rome in the subsequent year, for the purpose of renewing his studies and gaining a knowledge of anatomy. It was there in 1748 that his genius was first fully displayed in a picture of the "Holy Family." The model for the Virgin was a beautiful peasant girl, who in the same year became his wife, and induced him to embrace the Catholic religion. Returning to Dresden soon afterwards, he was appointed principal court-painter, and was presented by the king with a pension of 1000 dollars. A commission from the king to execute an altar-piece for the new chapel at Dresden rendered it necessary that he should return to Italy with his family in 1752. Simultaneously with the work just mentioned Mengs painted a copy of Raphael's "School of Athens" for Lord Percy, afterwards Duke of Northumberland. The outbreak of the Seven Years' War stopped the payment of his pension, and prevented his return to Saxony. This misfortune, however, was compensated by his appointment in 1754 to the professorship in the new academy of painting in the Capitol. Invited about this time to Naples, he executed the portraits of the Neapolitan royal family. On his return to Rome in 1757 he began his first attempt in fresco, the ceiling of the church of St Eusebio. His masterpiece, however, was the beautiful ceiling in the Villa Albani, representing "Apollo and the Nine Muses on Mount Parnassus." In 1761 Mengs, at the request of Charles III. of Spain, proceeded to Madrid, and was employed there for several years in executing an oil-painting of "The Passion," for the bed-chamber of the king, and some frescoes representing the "Birth of Aurora," the "Apotheosis of Hercules," and the "Apotheosis of Trajan." His declining health, however, rendered a change of climate necessary, and in 1769 he returned to Italy. After a sojourn of three years, occupied chiefly in the painting of the ceiling of the Camera de' Papiri at Rome, he repaired once more to Spain. But in 1775, when his constitution was almost prostrated under the uncongenial climate, he bade a final farewell to that country. On his arrival in Rome his sickness gradually left him, only to be brought back with overwhelming force by the death of his amiable wife in 1778. He died on the 29th June 1779. His friend, the Cavalier d'Azara, erected a monument to him, and obtained from the King of Spain pensions for his two sons and five daughters.

The character of his pictures is rather correct in design than vigorous, and his tone of colouring is deficient in brilliancy. His writings, edited in Italian by Azara in 1780, contain many excellent observations both on the practice and theory of his art. Among the various translations into the principal modern languages is one into English in 2 vols. 8vo, London, 1796.

MENG-TSEU, whose name has been Latinized into *Mencius*, the most eminent Chinese philosopher after Confucius, flourished during the first half of the fourth century b.c., and thus belonged to the same epoch with Socrates, Plato, and Aristotle. He was born in Tséou, a town in the province of Chan-toung, where his tomb is still shown. He lost his father, Meng-Kho, a short time after his birth, and his early education was left entirely in the hands of his mother, a woman still held in high veneration by the Chinese for the singular care and enlightenment which she displayed in the training of her fatherless boy. Persuaded that a bad example exercised a pernicious influence over the mind of the lad, she repeatedly changed her place of abode to remove him from temptation. She had the good fortune ultimately to settle down in the vicinity of a public school, which at once had the effect of stimulating his desire for knowledge. He became the disciple of Tseu-sse, the worthy descendant and representative of Confucius, under whom he made rapid advancement in the knowledge of the doctrines of that illustrious philosopher. Meng-Tseu soon found himself at the head of a group of ardent disciples, with whom he wandered about, a sort of Chinese Peripatetic, visiting, as the custom was, the different states of the empire at once to learn and to teach. Living in an epoch and in a country in which politics formed an integral part of morals, Meng-Tseu, both from the peculiar turn of his mind, and from his principles, felt disinclined to separate them. Accordingly, in his work, the *Meng*, which bears his name, he preserves a strict union between those two sciences. His politics appear to have displayed more decision and boldness than those of his master Confucius, for whom he constantly professed the highest admiration. While Meng-Tseu never ceases to inculcate the duty of political obedience, he nevertheless opposes strongly the law of justice to the tyrannous will of power. If he was less solid, he had a keener faculty than Confucius, and he assailed his adversary, whether prince or otherwise, with the most ruthless Socratic pertinacity, pursuing him from premise to conclusion, until he had him entangled in a network of absurdities. In his method and spirit he closely resembles his great Greek contemporary, the terror of the sophists; and there is perhaps no oriental philosopher who presents greater attractions to a European reader. He considered philosophy the great regenerator of the human race; and his work is one of the four classics which form the basis of instruction in all the public and private schools of China. The most eminent of her philosophers have expounded and commented on him, and his works are in the hands of all those who wish to attain to a knowledge of those eternal truths which form the most solid basis of human society. He died about the year 314 B.C. at the age of eighty-four.

Of Meng-Tseu's work, which has been frequently translated into different European languages, there is a Latin version by Stanislaus Julien, entitled *Meng-Tseu, vel Mencium inter Sinenses Philosophos ingenio, doctrina, &c., Confucio proximum edidit*, &c., 8vo., Paris, 1824–1829. There is also a French version by G. Pauthier in the *Livres Sacrés de l'Orient*, Paris, 1840; and in the volume of the Bibliothèque Charpentier, entitled *Confucius et Mencius, ou les Quatre Livres de Philosophie Morale et Politique de la Chine*, Paris, 1841; and there is an English translation of the *Four Books*, executed by the Rev. Mr Collie, and published at Malacca in 1828. (See *Dictionnaire des Sciences Philosophiques.*)

MENIN (Flemish *Meenen*), a town of Belgium, province of West Flanders, on the left bank of the Lys, 30 miles S. of Bruges, and 7 W.S.W. of Courtray. It is regularly built and strongly fortified, but has a dull and gloomy appearance. The principal building is the church; and there are also a college and several schools. The manufactures consist of linen, lace, soap, oil, tobacco, woollen stuffs, chocolate, and candles; and the town has also breweries, tanneries, dyeworks, and bleachfields. The trade consists in agricultural produce, horses, cattle, &c. Pop. 8268.

MENIPPUS, a Cynic philosopher, with whose private history we are but very slightly acquainted. It is supposed that he was a native of Gadara, a small village of Phœnicia (Strab. xvi. 759), and that he lived before the year 200 B.C., as he is spoken of by Hermippus, according to Diogenes Laërtius. He was originally a slave, but having purchased his liberty, he settled at Thebes, where he obtained the rights and privileges of a citizen. Lucian, in his *Dialogues of the Dead*, makes Diogenes describe him as "old, bald-headed, wearing a threadbare cloak, with abundance of apertures in it, pervious to every wind, and patched with rags of all possible colours; and as laughing incessantly at those conceited pedants the philosophers, who are generally the objects of his derision." Varro in his *Satires* imitated the style of Menippus, so that they were called *Satiræ Menippeæ*. (Cic. 1, 2; Gell. xi. 18., xiii. 30.)

MENNO, surnamed SIMONIS, the founder of the sect of the *Mennonites*, was born in 1505 at Witmarsum, a village near Bolswert in Friesland. At first he was a Roman Catholic priest, and was remarkable for nothing but gross sensuality. He then became a secret convert to the opinions of the Anabaptists, and in 1536 openly joined that body. With a change of opinions a change of morals had been simultaneous. He was now meek and gentle in disposition, kind and courteous to all men, blameless in his conduct, and full of apostolic zeal. With these qualities, a real though undisciplined genius, a rough and forcible eloquence, and a considerable amount of learning, combined to raise him to a high position in the sect which he had recently joined. He was accordingly requested in a short time to assume the functions of a public teacher. In this capacity he travelled with his wife and children through East and West Friesland, Gröningen, Holland, Guelderland, Brabant, Westphalia, and the German provinces on the coast of the Baltic. By rejecting most of the extreme tenets of the Anabaptists he attracted towards his ministrations the judicious and liberal-minded of that sect, and thus became the acknowledged head of a new body of separatists. As yet, however, the civil authorities recognised no distinction between his followers and the radical Anabaptists. Some of the Mennonites suffered martyrdom, and others, including their leader, escaped the same fate only by being received into the mansion of a kind-hearted nobleman in the duchy of Holstein. There they found a safe asylum from persecution, and there Menno Simonis died in 1561.

The *Mennonites* receive the old Anabaptist creed in a form modified and considerably altered. The dogmas regarding the millennium, the exclusion of magistrates from the church, the abolition of war, the sinfulness of taking oaths, and the vanity of human science, have lost much of the harshness of their original features, and appear in an aspect more conformable both to reason and revelation. At the same time, the distinctive doctrine of the Anabaptists, which declares that converts from other Christian churches ought to be rebaptized, is repudiated. The blind fanaticism that impelled the disciples of Anabaptism at the beginning of the sixteenth century to believe in the divine appointment of polygamy, to hold up the liberal arts to scorn and hatred, to encourage the assassination of impious magistrates, and to attempt to establish the kingdom of Sion in the city of Munster, is likewise utterly disowned. Indeed, so far have the Mennonites separated from the Anabaptists, that the former disclaim all connection with the latter, and believe that they have derived their origin and opinions from the ancient Waldenses. (See ANABAPTISTS.) The Mennonites are subdivided into several sects, slightly differing from each other. Of these the principal two are the *Flandrians* or *Flemingians*, and the *Waterlandians*. (Schyn's *Mennonitarum Historiæ*, and Mosheim's *Ecclesiastical History*.)

MENSURATION.

1. Mensuration, or the art of measuring, involves the construction of measures, the methods of using them, and the investigation of rules by which magnitudes, which it may be difficult or impossible to measure directly, are calculated from the ascertained value of some associated magnitude. It is usual, however, to employ the term mensuration in the last of these senses; and we may therefore define it to be that department of mathematical science by which the various dimensions of bodies are calculated from the simplest possible measurements.

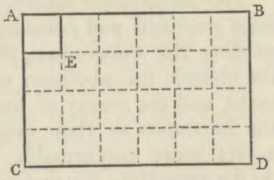
The determination of the lengths and directions of straight lines, including what are familiarly known as problems in heights and distances, generally depends on the solution of triangles, and will be discussed in the articles Trigonometry and Surveying. The remaining portions of the subject, which will form the subject of the present article, are the determinations of the lengths of curves, the areas of plane or other figures, and the volumes and surfaces of solids. Even thus restricted, the science of mensuration is obviously of very great extent, and our space will only permit us to discuss some of its more interesting and important problems.

The reader will find tables of the numbers most frequently required in mensuration at the end of this article, and a complete account of measures in the article Weights and Measures.

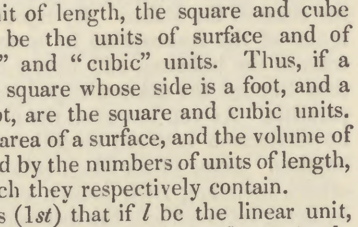
2. *On the Numerical Expression of the Length of a Line, the Area of a Surface, and the Volume of a Solid.*—If any line be chosen as the unit of length, the square and cube described upon it will be the units of surface and of volume, or the "square" and "cubic" units. Thus, if a foot be the linear unit, a square whose side is a foot, and a cube whose edge is a foot, are the square and cubic units. The length of a line, the area of a surface, and the volume of a solid, are then expressed by the numbers of units of length, surface, and volume which they respectively contain.

3. From this it follows (1*st*) that if l be the linear unit, the length of a line which contains a units is al; or simply a, for l is reckoned as unity.

4. (2*d*) If the length and breadth of a rectangle AD be divided into linear units, and lines be drawn through the points of section, parallel to its sides, it is evident that the rectangle will be divided into as many square units AE, as there are linear units in its length AB, repeated as often as there are linear units in its breadth AC; or the number of square units contained by the figure will be obtained by multiplying its length by its breadth. Hence if the length AB contain a, and the breadth AC contain b units, the surface AD will contain ab square units.



5. (3*d*) If the length, breadth, and height of a parallelopiped BCD be divided into linear units by planes drawn parallel to its faces, it will obviously be divided into cubic units such as EF; and if AB, AC, AD contain a, b, and c units respectively, it appears from the diagram that the portion of the solid between the face BC, and the plane passing through EG, EH, contains ab cubic units. Similarly, each of the sections of the solid between two contiguous planes passing through the divisions of AD, contains ab cubic units; and since AD is divided into c parts, the whole solid contains abc units of volume.



The demonstrations of the preceding propositions might be extended to include the cases where the linear dimensions are fractional, or incommensurable with the linear unit.

SECTION I.—PLANE FIGURES CONTAINED BY STRAIGHT LINES.

6. *To find the Area of a Rectangle.*—It has been proved in article 4, that if a and b be the sides of a rectangle,

$$\text{the area} = ab;$$

or the area of a rectangle is equal to its length multiplied by its breadth.

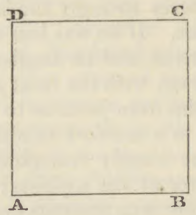
Whence, also, if a be the side of a square,

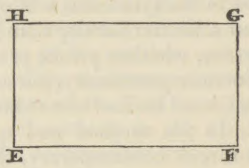
$$\text{the area of the square} = a^2.$$

Example 1.—Find the area of a square BD, whose side is 15 chains 40 links.

Here the side of the square = 1540 links; therefore

$$\text{the area} = (1540)^2 = 2371600 \text{ square links}$$
$$= 23 \text{ a. } 2 \text{ r. } 34{\cdot}56 \text{ p.}$$





Example 2.—Find the area of a rectangle EG, whose sides are 12 feet 6 inches and 9 inches.

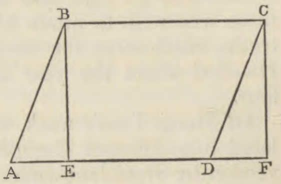
$$\text{The area} = 12{\cdot}5 \times {\cdot}75 = 9{\cdot}375 \text{ square feet.}$$

7. *To find the Area of a Parallelogram.*—(i.) *The area in terms of the base and perpendicular breadth.*

The parallelogram ABCD is equal to the rectangle BEFC (Geom., sec. iv., theor. 1; or, *Euc.* i., 35). Wherefore the area ABCD = BC·BE = AD·BE; and putting AD = b, and BE = h,

$$\text{the area} = bh;$$

or the area of a parallelogram is equal to its length, multiplied by its perpendicular breadth.



Example.—Find the area of a parallelogram whose length is 37 and its breadth $5\frac{1}{4}$ feet.

$$\text{The area} = 37 \times 5{\cdot}25 = 194{\cdot}25 \text{ square feet.}$$

8. (ii.) *The area in terms of the sides and the included angle.*—Let AB = a, AD = b, angle BAD = A.

Then BE = a sin A; and since ABCD = BE·AD,

$$\text{the area} = ab \sin \text{A}.$$

Whence the area is obtained by multiplying together the two sides of the parallelogram and the sine of the contained angle.

Example.—The sides of a parallelogram are 36 and 25·5, and the contained angle 58°.

$$\text{The area} = 36 \times 25{\cdot}5 \times \sin 58° = 36 \times 25{\cdot}5 \times {\cdot}8480481$$
$$= 778{\cdot}50:$$

or $\log \text{area} = \log a + \log b + \text{L} \sin \text{A} - 10$*

$a = 36$ $\qquad \log a = 1·5563025$

$b = 25·5$ $\qquad \log b = 1·4065402$

$\text{A} = 58°$ $\qquad \text{L} \sin \text{A} = 9·9284205$

Area $= 778·5$ $\qquad \log \text{area} = \overline{2·8912632}$

9. (iii.) *The area in terms of the diagonals and their contained angle.*

If m, n are the diagonals, and I the contained angle, it follows, from article 17, that the

$$\text{area} = \tfrac{1}{2} mn \sin \text{I}.$$

Example.—Find the area of a parallelogram whose diagonals, are 30 and 25, which make with each other an angle of 60°.

$$\text{Area} = \tfrac{1}{2} \times 30 \times 25 \times \sin 60° = 15 \times 25 \times ·8660254$$
$$= 324·76;$$

or $\log \text{area} = \log m + \log n + \text{L} \sin \text{I} - \log. 2 - 10.$

$m = 30$ $\qquad \log m = 1·4771213$

$n = 25$ $\qquad \log n = 1·3979400$

$\text{I} = 60°$ $\qquad \text{L} \sin = 9·9375306$

$\qquad \text{colog } 2 = 9·6989700$

Area $= 324·76$ $\qquad \log \text{area} = \overline{2·5115619}$

If the parallelogram is equilateral, or a rhombus, the diagonals intersect at right angles, and $\sin \text{I} = \sin 90° = 1$.

$$\text{Whence the area} = \tfrac{1}{2} mn.$$

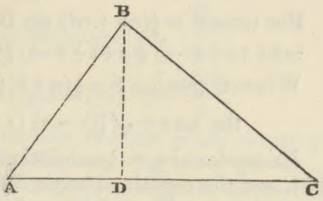
Example.—Find the area of a rhombus whose diagonals are 30 and 20 chains.

$$\text{The area} = \tfrac{1}{2} \times 30 \times 20 = 300 \text{ chains} = 30 \text{ acres}.$$

10. *To find the Area of a Triangle*—(i.) *When the base* AC, *and height* BD *are given.*—Let $\text{AC} = b$, $\text{BD} = h$. Then, since a triangle is half a rectangle of the same base and altitude (GEOM. p. 520), the area of the triangle

$$= \tfrac{1}{2} bh;$$

or the area is equal to one-half the product of one of the sides multiplied by the perpendicular let fall upon it from the opposite angle of the triangle.



Example.—A side of a triangle is 40, and the perpendicular on it from the opposite angle is 14·52 chains.

$$\text{The area} = \tfrac{1}{2} \times 40 \times 14·52 = 290·4 \text{ sq. chains}.$$
$$= 29 \text{ a. } 0 \text{ r. } 6·4 \text{ p.}$$

11. (ii.) *When two sides and the included angle are given.*—Let $\text{AC} = b$, $\text{AB} = c$.

Since $\text{ABC} = \tfrac{1}{2} \text{AC} \cdot \text{BD}$, and $\text{BD} = c \sin \text{A}$,

$$\text{the area of the triangle} = \tfrac{1}{2} bc \sin \text{A};$$

or the area is equal to one-half the continued product of the two sides, and the sine of the contained angle.

Example.—The sides of a triangle are 30 and 40, and the contained angle is 28° 57.′

$$\text{The area} = \tfrac{1}{2} \times 30 \times 40 \times \sin 28° \, 57' = 600 \times ·4840462$$
$$= 290·43;$$

or, by logarithms—

$\text{Log area} = \log b + \log c + \text{L} \sin \text{A} + \text{colog } 2 - 10$

$b = 30$ $\qquad \log \tfrac{1}{2} b = 1·1760913$

$c = 40$ $\qquad \log c = 1·6020600$

$\text{A} = 28° \, 57'$ $\qquad \text{L} \sin \text{A} = 9·6848868$

Area $= 290·43$ $\qquad \log \text{area} = \overline{2·4630381}$

12. *When the three sides of the triangle are given.*—Let $\text{BC} = a$, $\text{AC} = b$, $\text{AB} = c$; and put $\text{BD} = x$, and $\text{AD} = y$. Then $\text{CD} = b - y$;

$$\therefore c^2 = x^2 + y^2, \text{ and } a^2 = x^2 + (b - y)^2.$$

$$\text{Whence } y = \frac{b^2 + c^2 - a^2}{2b}.$$

$$\text{But } x^2 = c^2 - y^2 = c^2 - \left(\frac{b^2 + c^2 - a^2}{2b}\right)^2$$
$$= \frac{(a+b+c)\,(b+c-a)\,(a+c-b)\,(a+b-c)}{4b^2}.$$

Whence, since the square of the area of the triangle is $(\tfrac{1}{2}\text{AC} \cdot \text{DB})^2 = \tfrac{1}{4} b^2 x^2$, we have

$$(\text{area})^2 = \tfrac{1}{2}(a+b+c)\,\tfrac{1}{2}(b+c-a)\,\tfrac{1}{2}(a+c-b)\,\tfrac{1}{2}(a+b-c).$$

Now if we put $s = \tfrac{1}{2}(a+b+c)$, then $\tfrac{1}{2}(b+c-a) = s - a$, &c. Therefore substituting

$$\text{The area of the triangle} = \sqrt{\{s(s-a)\,(s-b)\,(s-c)\}}.$$

$$\text{Otherwise, since } \sin \text{A} = \frac{2}{bc} \sqrt{\{s(s-a)\,(s-b)\,(s-c)\}},$$

$$\text{the triangle} = \frac{bc}{2} \sin \text{A} = \sqrt{\{s(s-a)\,(s-b)\,(s-c)\}}.$$

Whence, to obtain the area of a triangle, from half the sum of the three sides, subtract each side separately, multiply the half sum by the three remainders successively, and extract the square root.

Example 1.—The sides of a triangle are 3, 4, and 5 feet. Find its area.

$a = 5$, $b = 4$, $c = 3$.

$s = \tfrac{1}{2}(5 + 4 + 3) = 6$; $s - a = 1$; $s - b = 2$; $s - c = 3$.

$$\text{The area} = \sqrt{6 \times 1 \times 2 \times 3} = \sqrt{36} = 6 \text{ square feet.}$$

Example 2.—The sides of a triangle are 221, 255, and 238.

$a = 255$

$b = 238$

$c = 221$

$2)\overline{714}$

$s = 357$ $\qquad \log = 2·5526682$

$s - a = 102$ $\qquad$ „ $= 2·0086002$

$s - b = 119$ $\qquad$ „ $= 2·0755470$

$s - c = 136$ $\qquad$ „ $= 2·1335389$

$\qquad 2)\overline{8·7703543}$

Area $= 24276$ $\qquad \log \text{area} = 4·3851772$

13. *When two angles and the adjacent side are given.*—Let the angles A, B and the side c be given.

$$\text{The area} = \tfrac{1}{2} bc \sin \text{A}.$$

$$\text{But } b = \frac{c \sin \text{B}}{\sin \text{C}} = \frac{c \sin \text{B}}{\sin (\text{A} + \text{B})}; \quad \because \sin \text{C} = \sin (\text{A} + \text{B}).$$

Therefore substituting,

$$\text{the area} = \frac{c^2 \sin \text{A} \sin \text{B}}{2 \sin (\text{A} + \text{B})}$$
$$= \tfrac{1}{2} c^2 \sin \text{A} \sin \text{B} \operatorname{cosec} (\text{A} + \text{B});$$

and $\log \text{area} = 2 \log c + \text{L} \sin \text{A} + \text{L} \sin \text{B} + \text{L} \operatorname{cosec} (\text{A} + \text{B}) + \text{colog } 2 - 40.$

Example.—The side of a triangle is 2405 feet, and the angles at its ends 77° 54′, and 87° 40′. Find its area in square miles.

$c = 2405$ $\qquad 2 \log c = 6·7622302$

$\text{A} = 77° \, 54'$ $\qquad \text{L} \sin \text{A} = 9·9902426$

$\text{B} = 87 \;\; 40$ $\qquad \text{L} \sin \text{B} = 9·9996398$

$\text{A} + \text{B} = 165 \;\; 34$ $\qquad \text{L} \cos (\text{A} + \text{B}) = 10·6033590$

$\qquad \text{colog } 2 = 9·6989700$

$\qquad \text{log area in ft.} = \overline{7·0544416}$

$\qquad 2 \log 5280 = 7·4452678$

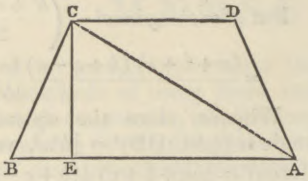
Area $= 0·40661$ sq. miles. $\qquad$ log. area in miles $= \bar{1}·6091738$

14. *To find the Area of a Trapezoid.*—Let $\text{AB} = a$, $\text{CD} = b$, $\text{CE} = h$. Then $\text{ABCD} = \text{ABC} + \text{ACD} = \tfrac{1}{2} ah + \tfrac{1}{2} bh$ (art. 10).

---

* Throughout this article we shall denote the logarithm of a number to the base 10, by $\log_{10} n$ or simply $\log n$; and the tabular logarithm of the sine, cosine, &c., of an angle A by L sin A, L cos A, &c. Since the logarithmic sines, cosines, &c., in the tables, are all increased by 10, we have $\text{L} \sin \text{A} = \log_{10} \sin \text{A} + 10$, &c. We shall also denote the arithmetical complement of $\log n$, or $10 - \log n$, by colog n.

Hence the trapezoid ABCD $= \frac{1}{2}(a+b)h$;
or the area is equal to half the sum of the parallel sides multiplied by the perpendicular breadth.

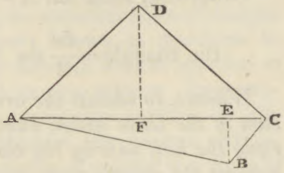


Example.—Find the area of a trapezoid whose parallel sides are 12·25 and 7·5 chains, and its breadth 15·4.

The area $= \frac{1}{2} \times (12{\cdot}25 + 7{\cdot}5) \times 15{\cdot}4 = 7{\cdot}7 \times 19{\cdot}75$
$= 152{\cdot}075$ square chains.
= 15 a. 0 r. 32·2 p.

15. *To find the Area of a Quadrilateral Figure*—(i.) *When a diagonal* AC *and perpendiculars* DF, BE *are given.*—Let AC $= a$, BE $= m$, and DF $= n$. Then ABCD = ABC + ADC $= \frac{1}{2}am + \frac{1}{2}an$ (art. 10); or,

the quadrilateral $= \frac{1}{2}a(m+n)$.



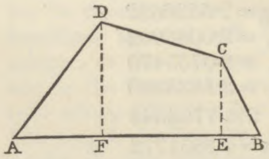
Hence the area is obtained by multiplying the diagonal by half the sum of the perpendiculars.

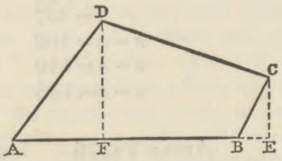
Example.—In a quadrilateral the diagonal is 42, and the perpendiculars 16 and 18.

The area $= \frac{1}{2} \times 42 \times (16+18) = 21 \times 34 = 714$.

16. (ii.) *When a side* AB *and the perpendiculars* DF, CE *are given.*

The area = ADF + CDEF + BCE.
$= \frac{1}{2}$AF·DF $+ \frac{1}{2}$(DF + CE) EF $+ \frac{1}{2}$BE·CE (arts. 10, 14)
$= \frac{1}{2}$(AE·DF + BF·CE).

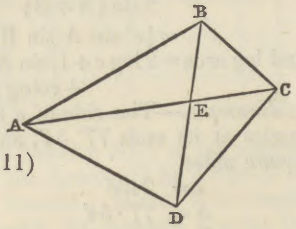




Example.—Let AB = 12, AF = 5, BE = 3, DF = 8, and CE = 6. Then AE = 12 ± 3 = 15 or 9.
BF = 12 − 5 = 7

The area $= \frac{1}{2}(9 \times 8 + 7 \times 6) = 4 \times 9 + 3 \times 7 = 57$; or,
$= \frac{1}{2}(15 \times 8 + 7 \times 6) = 4 \times 15 + 3 \times 7 = 81$.

17. (iii.) *When the diagonals and the included angle are given.*—Let AC $= m$, BD $= n$, AEB = I;
∴ BEC = 180° − AEB;
∴ Sin BEC = sin I.
ABC = ABE + BCE
$= \frac{1}{2}$AE·BE sin AEB
$+ \frac{1}{2}$CE·BE sin BEC (art. 11)
$= \frac{1}{2}$AC·BE sin AEB.



Similarly ADC $= \frac{1}{2}$AC · DE sin AEB.
Whence ABCD $= \frac{1}{2}$AC · BD sin AEB; or,

the area $= \frac{1}{2}mn$ sin I.

Therefore the area of a quadrilateral is equal to half the product of the diagonals, and the sine of their contained angle.

This rule obviously applies to parallelograms.

Example.—The diagonals of a quadrilateral are 30 and 40, and the included angle 48°.

The area $= \frac{1}{2} \times 30 \times 40 \times \sin 48°$
$= 600 \times {\cdot}7431448$
$= 435 \cdot 887$.

18. (iv.) *When the sides and the angle between the diagonals are given.*—In the figure of article 17, let AB $= a$, BC $= b$, CD $= c$, AD $= d$, BEC = I, AE $= x$, BE $= y$, EC $= z$, ED $= w$.

$$\text{Then } x^2 + y^2 + 2xy \cos \text{I} = a^2$$
$$y^2 + z^2 - 2yz \cos \text{I} = b^2$$
$$z^2 + w^2 + 2zw \cos \text{I} = c^2$$
$$w^2 + x^2 - 2wx \cos \text{I} = d^2$$

Whence $2(x+z)(y+w) \cos \text{I} = a^2 - b^2 + c^2 - d^2$.
But $2(x+z)(y+w) \cos \text{I} = \frac{1}{2}$AC·BD sin I × 4 cot I,
= area ABCD × 4 cot I (art. 17).

Therefore the area $= \frac{1}{4}(a^2 - b^2 + c^2 - d^2) \tan \text{I}$.

Example.—The sides of a quadrilateral in order are 10, 9, 8, and 7, and the angle between the diagonals is 80°. Find the area.

$$a^2 - b^2 + c^2 - d^2 = 100 - 81 + 64 - 49 = 34.$$

∴ log area = log 34 + L tan 80° + colog 4 − 10

log 34 = 1·5314789
L tan 80° = 10·7536812
colog 4 = 9·3979400
Area = 48·206. log area = 1·6831001

19. (v.) *When the quadrilateral is inscribed in a circle.*—In the figure of article 17, let AB $= a$, BC $= b$, CD $= c$, AD $= d$. Then, since the quadrilateral is inscribed in a circle, D = 180° − B;

and $a^2 + b - 2ab \cos \text{B} = \text{AC}^2 = c^2 + d^2 + 2cd \cos \text{B}$.

$$\text{From which } \cos \text{B} = \frac{a^2 + b^2 - c^2 - d^2}{2(ab + cd)}.$$

But $(\text{area})^2 = \frac{1}{4}(ab + cd) \sin \text{B}$
$= \frac{1}{2}(b+c+d-a)\,\frac{1}{2}(a+c+d-b)\,\frac{1}{2}(a+b+d-c)\,\frac{1}{2}(a+b+c-d)$.

Whence putting $\text{S} = \frac{1}{2}(a+b+c+d)$,

$$\text{the area} = \sqrt{\{(s-a)(s-b)(s-c)(s-d)\}}.$$

Example.—In a quadrilateral, two sides are 120 and 104, and the contained angle 59° 29′ 23″; and the remaining sides are 78 and 50, and the contained angle 120° 30′ 37″.

Since the sum of the opposite angles = 180°, the figure may be inscribed in a circle, and the formula applies.

$a = 120$
$b = 104$
$c = 78$
$d = 50$
352
$s = 176$
$s - a = 56$ log = 1·7481880
$s - b = 72$ " = 1·8573325
$s - c = 98$ " = 1·9912261
$s - d = 126$ " = 2·1003705
2)7·6971171
Area = 7056 log area = 3·8485586

20. (vi.) *When the four sides of the quadrilateral and a pair of opposite angles are given.*—Since the figure (art. 17) may be divided into two triangles whose areas can be found by article 11; if a, b, c, and d be the sides, we have evidently

the area $= \frac{1}{2}(ab \sin \text{B} + cd \sin \text{D})$.

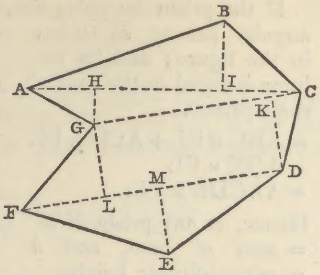
Example.—To verify the calculation of the area in the example of last article.

$a = 120$	log $a = 2{\cdot}0791812$	$c = 78$	log $c = 1{\cdot}8920946$
$b = 104$	log $b = 2{\cdot}0170333$	$d = 50$	log $d = 1{\cdot}6989700$
B = 59°29′23″	L sin B = 9·9352745	D = 120°30′37″	L sin D = 9·9352745
2ABC = 10752	4·0314890	2ADC = 3360	3·5263391

∴ 2ABCD = 14112, and ABCD = 7056.

21. *To find the Area of an Irregular Polygon.*—The figure may be divided into triangles or trapeziums;

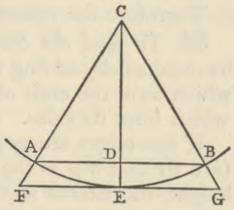
whose areas, found separately and added, will give that of the whole figure.



Example.—In the figure AD are given the diagonals AC = 5·5, CG = 4·4, FD = 5·2, and the perpendiculars BI = 1·8, GH = 1·3, DK = 2·3, GL = 1·2, EM = 0·8. Then, by articles 10 and 14,

$$\begin{aligned} 2\ \mathrm{ABCG} &= \mathrm{AC}\ (\mathrm{BI}+\mathrm{GH}) = 5{\cdot}5\ (1{\cdot}8+1{\cdot}3) = 17{\cdot}05 \\ 2\ \mathrm{DEFG} &= \mathrm{DF}\ (\mathrm{GL}+\mathrm{EM}) = 5{\cdot}2\ (1{\cdot}2+0{\cdot}8) = 10{\cdot}40 \\ 2\ \mathrm{CDG} &= \mathrm{CG}{\cdot}\mathrm{DK} = 4{\cdot}4 \times 2{\cdot}3 = 10{\cdot}12 \\ 2\ \text{area} &= 37{\cdot}57 \\ \text{area} &= 18{\cdot}785 \end{aligned}$$

22. *To find the Area of a Regular Polygon.*—If AB be one of the sides of the polygon, and C the centre of the circle described about it, the area of the polygon will be equal to that of the triangle ABC multiplied by the number of sides.



Let AB = a, and the number of sides = n. Then, since the equal sides of the polygon subtend equal angles at the centre of the circle, $\mathrm{ACB} = \frac{360^\circ}{n}$;

$$\therefore\ \mathrm{CD} = \mathrm{AD}\cot\mathrm{ACD} = \tfrac{1}{2}a\ \cot\frac{180^\circ}{n};$$

$$\text{and the triangle } \mathrm{ABC} = \mathrm{AD}{\cdot}\mathrm{DC} = \tfrac{1}{4}a^2\ \cot\frac{180}{n};$$

$$\text{whence the polygon} = \tfrac{1}{4}na^2\cot\frac{180^\circ}{n}.$$

(i.) *Hence the area of a regular polygon is one-fourth of the continued product obtained by squaring one of its sides, multiplying by the number of its sides and by the cotangent of the angle obtained by dividing* 180° *by the number of its sides.*

Example.—Find the area of a regular polygon whose side is 23 and the number of sides 15.

$$\text{Log area} = \log n + 2\log a + \mathrm{L}\cot\frac{180^\circ}{n} + \text{colog}\ 4 - 20.$$

$$\begin{array}{lrr} a = 23 & \log a = & 1{\cdot}3617272 \\ n = 15 & & 2 \\ \frac{180^\circ}{n} = 12^\circ & & \overline{2{\cdot}7234556} \\ & \log n = & 1{\cdot}1760913 \\ & \mathrm{L}\cot\frac{180^\circ}{n} = & 10{\cdot}6725255 \\ & \text{colog}\ 4 = & 9{\cdot}3979400 \\ \text{Area} = 9332{\cdot}8 & \log\text{area} = & \overline{3{\cdot}9700124} \end{array}$$

23. (ii.) If the side of the polygon = 1, its area $= \frac{n}{4}\cot\frac{180^\circ}{n}$; and the area of a polygon whose side is a, may then be obtained by multiplying by a^2. Since the number by which a^2 is to be multiplied is the *same* for all polygons of the same number of sides, it is obvious that if its values be calculated for $n=3$, $n=4$, &c., and the results collected in a table, *we shall obtain the area of any polygon by multiplying the square of its side by the appropriate tabular number.*

Table I. contains the multipliers and their logarithms for polygons of 3 to 12 sides.

Examples.—Find the areas of a regular pentagon whose side is 25, and of a hexagon whose side is 20.

The multiplier for the pentagon is 1·7204774;

$\therefore$ the pentagon = $(25)^2 \times 1{\cdot}7204774 = 1075{\cdot}298$.

To find the area of the hexagon by logarithms.

$$\begin{array}{lr} \text{The logarithm for a hexagon} = & {\cdot}4146519 \\ 2\log 20 = & \underline{2{\cdot}6020600} \\ \text{Area of hexagon} = 1039{\cdot}230 & 3{\cdot}0167119 \end{array}$$

24. *To find the Area of a Regular Polygon inscribed in a Circle.*—Let AB (fig. art. 22) be a side of the polygon; the radius AC = r, and the number of sides = n.

$$\text{Then ACD} = \frac{180^\circ}{n};$$

$$\therefore\ \mathrm{AD} = r\sin\frac{180^\circ}{n},\ \text{and CD} = r\cos\frac{180^\circ}{n};$$

and since the polygon = nABC = nAD · DC,

$$\text{its area} = nr^2\sin\frac{180^\circ}{n}\cos\frac{180^\circ}{n} = \tfrac{1}{2}nr^2\sin\frac{360^\circ}{n}.$$

Example.—The radius of a circle being 10, find the area of an inscribed hexagon.

$$\begin{aligned} \text{The area} &= \tfrac{1}{2}\times 6\times 100\sin 60^\circ = 300\times\frac{\sqrt{3}}{2} \\ &= 150\times 1{\cdot}7320508 = 259{\cdot}81. \end{aligned}$$

25. *To find the Area of a Regular Polygon described about a Circle.*—In fig. to article 22, if FG be a side of the polyglon of n sides; since FG = CE · tan ECF = r tan $\frac{180^\circ}{n}$, and the polygon = nCFG = nCE · EF;

$$\text{therefore area} = nr^2\tan\frac{180^\circ}{n}.$$

Example.—Find the area of a regular hexagon described about a circle whose radius is 10 feet.

$$\begin{aligned} \text{Area} &= 6\times 100\times\tan 30^\circ = 600\times\frac{1}{\sqrt{3}} = 200\sqrt{3} \\ &= 200\times 1{\cdot}7320508 = 346{\cdot}41. \end{aligned}$$

SECTION II.—SOLIDS CONTAINED BY PLANES.

26. *To find the Volume of a Rectangular Parallelopiped.*—If the parallelopiped be rectangular, and its edges be a, b, and c, it has been proved in article 5, that its

$$\text{volume} = abc;$$

or the volume is equal to the length multiplied by the breadth and by the height.

Example.—The volume of a parallelopiped whose length, breadth, and height are 5, 4, and 3,

$$= 5\times 4\times 3 = 60.$$

27. *To find the Surface of a Rectangular Parallelopiped.*—The surface of the parallelopiped (fig. art. 5) is evidently

$$= 2\mathrm{BC} + 2\mathrm{BD} + 2\mathrm{CD};$$

$$\therefore\ \text{surface} = 2(ab + ac + bc.)$$

Hence the surface is double the sum obtained by adding together the length multiplied by the breadth, the length multiplied by the height, and the breadth multiplied by the height.

Example.—The surface of the rectangular parallelopiped, whose length, breadth, and thickness are 5, 4, and 3,

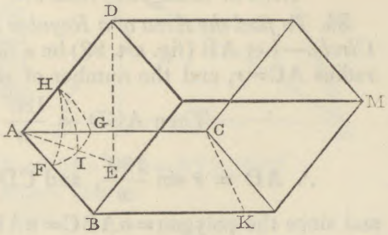
$$= 2(5\times 4 + 5\times 3 + 4\times 3) = 2(20+15+12) = 94.$$

28. *To find the Volume of any Parallelopiped*—(i.) *When the length AC of the base BC* (fig. art. 29), *its perpendicular breadth CK, and the altitude DE of the parallelopiped are given.*—It is proved (GEOM. p. 536; *Euc.* xi. 34), that a parallelopiped is equal to any other parallelopiped having an equal base and the same altitude; and as this other parallelopiped may be rectangular, its volume = base × height (art. 26). Hence the volume of the parallelopiped AM = AC·CK·DE; or if AB = l, KL = m, and DE = n,

$$\text{the volume} = lmn.$$

Example.—If the length of the base be 57, its perpendicular breadth $5\frac{1}{4}$, and the height of the parallelopiped 13, its volume $=57\times 5{\cdot}25\times 13=2525{\cdot}25$.

29. (ii.) *Given the edges of a parallelopiped, and their inclinations, to find its volume.*—Let AM be the parallelopiped, DE a perpendicular from D upon BC; and let a spherical surface whose centre is A, cut the faces of the parallelopiped in the arcs FH, FG, GH, and the plane ADE in the arc HI.



Let AB $=a$, AC $=b$, AD $=c$, and the angles BAC $=\alpha$, BAD $=\beta$, CAD $=\gamma$. In the spherical triangle FGH,

$$\sin F=\frac{2}{\sin\alpha\sin\beta}\sqrt{\{\sin s\sin(s-\alpha)\sin(s-\beta)\sin(s-\gamma)\}},$$

$$\text{where}\quad s=\tfrac{1}{2}(\alpha+\beta+\gamma),$$
$$\text{and}\ \sin HI=\sin\beta\sin F;$$

also $DE=AD\sin DAE=c\sin HI=c\sin\beta\sin F$;

and the parallelopiped

$$=\text{parallelogram } BC\times DE=DE\times ab\sin\alpha\ \text{(art. 8)};$$

therefore the volume

$$=2abc\sqrt{\{\sin s\sin(s-\alpha)\sin(s-\beta)\sin(s-\gamma)\}}.$$

Example.—The edges of a parallelopiped are 4, 5, and 6, and their inclination 40°, 50°, and 60°. Find the volume.

$$\begin{array}{rcrlr}
\alpha & = & 40^\circ & & \\
\beta & = & 50 & & \\
\gamma & = & 60 & & \\
\hline
 & & 150 & & \\
S & = & 75 & \log\sin = & \bar{1}{\cdot}9849438 \\
s-\alpha & = & 35 & \ldots = & \bar{1}{\cdot}7585913 \\
s-\beta & = & 25 & \ldots = & \bar{1}{\cdot}6259483 \\
s-\gamma & = & 15 & \ldots = & \bar{1}{\cdot}4129962 \\
\hline
 & & & 2) & \bar{2}{\cdot}7824796 \\
\hline
 & & & & \bar{1}{\cdot}3912398 \\
a & = & 4 & \log a = & {\cdot}6020600 \\
b & = & 5 & \log b = & {\cdot}6989700 \\
c & = & 6 & \log c = & {\cdot}7781513 \\
 & & & \log 2 = & {\cdot}3010300 \\
\hline
\end{array}$$

Volume $=59{\cdot}0814$ log volume $=1{\cdot}7714511$

30. *The Surface of the Parallelopiped.*—From art. 8 the surface is evidently

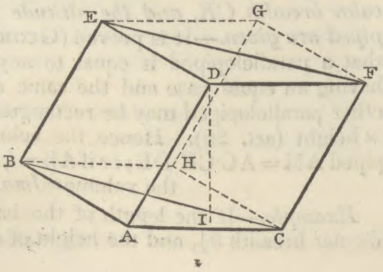
$$=2(ab\sin\alpha+ac\sin\beta+bc\sin\gamma).$$

Example.—Find the surface of the parallelopiped in example to art. 29.

$$a=4,\ b=5,\ c=6,\ \alpha=40^\circ,\ \beta=50^\circ,\gamma=60^\circ.$$

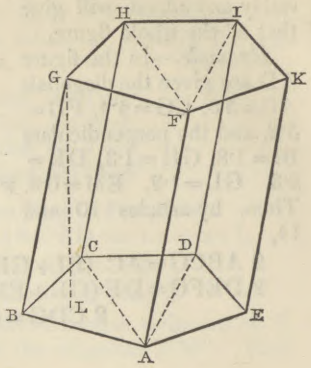
$$\begin{array}{rlrl}
\text{Log } a = & {\cdot}6020600 & \therefore\ BC = & 12{\cdot}856 \\
\log b = & {\cdot}6989700 & \text{similarly } BD = & 18{\cdot}385 \\
4\sin\alpha = & 9{\cdot}8080675 & \text{and } CD = & 25{\cdot}981 \\
\hline
\text{Log area } BC = & 1{\cdot}1090975 & & 57{\cdot}222 \\
 & & \therefore\ \text{Surface} = & 114{\cdot}444
\end{array}$$

31. *To find the Volume of a Prism.*—If the parallelopiped AG be cut by a plane BEFC, it will be divided into two equal prisms (GEOMETRY, p. 536, theor. iv.; *Euc.* xi. 28). Therefore the prism AEF $=\tfrac{1}{2}$AG $=\tfrac{1}{2}$ABHC × DI (art. 28) = ABC × DI.



If the prism be polygonal, it may be divided into triangular prisms, as shown in the figure; and its volume is equal to the sum of these prisms.

$$=ABC\times FL+ACD\times FL$$
$$+ADE\times FL$$
$$=ABCDE\times FL.$$



Hence, in any prism, if m^2 = area of base, and h = perpendicular height,

$$\text{the volume}=m^2h\,;$$

or the volume of any prism is equal to its base multiplied by its height.

Example.—The sides of the base of a triangular prism are 3, 4, and 5 feet, and its height 7 feet. What is its volume?

The area of the base = 6 square feet (ex. 1, art. 12);
Therefore the volume $=6\times 7=42$ cubic feet.

32. *To find the Surface of a Prism.*—The surface will be obtained by adding the areas of the triangles or polygons which form the ends of the solid, and of the parallelograms which form its sides.

If the edges are perpendicular to the base, it is evident (art. 6) that if p = the perimeter of the base, and h = the height, the lateral surface $=ph$;

and m^2 being the area of the end, the whole surface

$$=ph+2m^2.$$

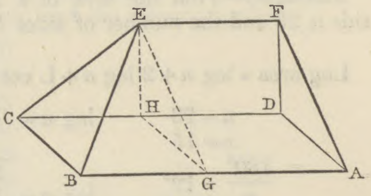
Example.—Find the volume and surface of a prism whose base is a regular polygon of 15 sides, a side of the base 23 feet, and the height 75 feet.

The area of the base $=9332{\cdot}8$ square feet (ex. art. 22);
Therefore the volume $=75\times 9332{\cdot}8=699960$ cubic feet.

Also if the edges are perpendicular to the base, the surface

$$=2\times 9332{\cdot}8+15\times 23\times 75$$
$$=44540{\cdot}6 \text{ square feet.}$$

33. *To find the Volume of a Wedge.*—The base AC of the wedge is a parallelogram, and the edge EF is parallel to AB or CD. If the plane EHG be parallel to ADF, the wedge will be equal to the sum or difference of the prism AEHG, and the pyramid CEG.



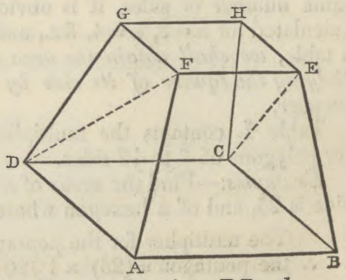
Therefore, if AB $=a_1$, EF $=a_2$, a perpendicular from A upon CD $=b$, and a perpendicular from F upon the plane AC $=h$, the wedge

$$=\tfrac{1}{2}AG\times bh\pm\tfrac{1}{3}BG\times bh\ \text{(arts. 31 and 35)}$$
$$=\tfrac{1}{2}a_2bh\pm\tfrac{1}{3}(a_1\ a_2)\,bh=bh\left(\frac{a_2}{2}+\frac{a_1-a_2}{3}\right)$$
$$=\tfrac{1}{6}bh(2a_1+a_2).$$

Example.—The length and breadth of the base of a wedge are 32 and 9, and the height 28 feet.

$$\text{The volume}=\tfrac{1}{6}\times 9\times 28\,(64+21)=3570.$$

34. *To find the Volume of a Rectangular Prismoid.*—The faces BD and GE are rectangles, whose planes and sides are parallel; hence the figure is evidently a frustum of a pyramid.



Let AB $=a_1$, AD $=b_1$, EF $=a_3$, FG $=b_3$, and the perpendicular from F upon the plane DB $=h$.

The prismoid = wedge AED + wedge DEH

$$=\tfrac{1}{6}b_1h(2a_1+a_3)+\tfrac{1}{6}b_3h(2a_3+a_1)$$
$$=\tfrac{1}{6}h\{a_1b_1+a_3b_3+(a_1+a_3)(b_1+b_3)\}.$$

But if the figure were cut by a plane parallel to, and equidistant from the planes AC, EG, and if a_2, b_2 be the length and breadth of this plane reckoned respectively parallel to AD, AB,

$$\text{then } a_2=\frac{a_1+a_3}{2};\ b_2=\frac{b_1+b_3}{2}.$$

Hence substituting

$$\text{the prismoid}=\tfrac{1}{6}h\,(a_1b_1+4a_2b_2+a_3b_3).$$

Since a_1b_1, a_2b_2, a_3b_3, are the areas of the ends, and what may be termed the middle section of the figure parallel to the ends, *the volume of the prismoid is obtained by adding together the areas of its ends, and four times the area of its middle section, and multiplying the sum by one-sixth of the height.*

Example.—The sides of the base of a rectangular prismoid are 12 and 8; the sides of the top respectively parallel to those of the base are 6 and 4; and the height is 5.

$$\text{Here } a_1=12,\ a_3=6,\ b_1=8,\ b_3=4,\ h=5.$$

$$a_2=\frac{a_1+a_3}{2}=9;\quad b_2=\frac{b_1+b_3}{2}=6.$$

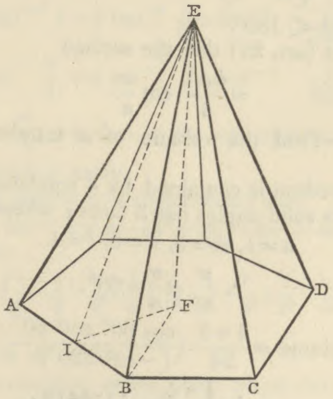
$$\text{The volume}=\tfrac{5}{6}(12\times 8+4\times 9\times 6+4\times 6)=280.$$

35. *To find the Volume of any Pyramid.*—The volume of a pyramid is one-third of that of a prism of the same base and altitude (Geom. p. 539, theor. 17, cor. 1; *Euclid* xii. 7, cor. 1). It therefore follows (art. 31) that if a^2 = the base, and h = the height,

$$\text{the volume}=\tfrac{1}{3}m^2h;$$

or the volume is one-third of the product of the base multiplied by the height.

36. *To find the Volume of a Right Pyramid.*—The base AD is supposed to be a regular polygon; F is the centre of a circle described about the polygon AD, and EF is perpendicular to the plane AD. EI, perpendicular to AB, is the "slant height."



Let AB = a, EF = h, EI = l, n = the number of sides of the polygon.

$$\text{The area AD}=\tfrac{1}{4}na^2\cot\frac{180^\circ}{n}\ \text{(art. 22)};$$

and hence, since (art. 35) the pyramid = ⅓AD, EF,

$$\text{its volume}=\tfrac{1}{12}na^2h\cot\frac{180^\circ}{n}.$$

37. *To find the Surface of a Right Pyramid.*—The lateral surface of the pyramid $=n\text{ABE}=n\text{AI}\cdot\text{EI}=\tfrac{1}{2}nal$.

$$\text{Hence the whole surface}=\tfrac{1}{2}na\left(l+\tfrac{1}{2}a\cot\frac{180^\circ}{n}\right).$$

In the triangle EFI,

$$\text{EI}^2=\text{EF}^2+\text{FI}^2=\text{EF}^2+\text{IB}^2\cot^2\text{BFI},$$

$$\therefore\ l^2=h^2+\tfrac{1}{4}a^2\cot^2\frac{180^\circ}{n};$$

by which, according to the data given for calculating the surface and volume of the pyramid, we may obtain l from h, or h from l.

Example.—Find the volume and surface of an hexagonal pyramid, each side of the base being 2 feet 6 inches, and the length of the axis 10 feet.

$$a=2{\cdot}5,\ h=10,\ n=6;\ \therefore\ \frac{180^\circ}{n}=30^\circ.$$

$$\begin{array}{rr}
\text{Log }\tfrac{1}{2}a= & {\cdot}0969100\\
\text{L Cot }30^\circ= & 10{\cdot}2385606\\
\hline
 & {\cdot}3354706\\
 & 2\\
\hline
\log\tfrac{1}{4}a^2\cot^2\dfrac{180^\circ}{n}= & {\cdot}6709412
\end{array}
\qquad
\begin{array}{rl}
\text{hence }\tfrac{1}{4}a^2\cot^2\dfrac{180^\circ}{n}= & 4{\cdot}687\\
h^2= & 100{\cdot}000\\
\hline
l^2= & 104{\cdot}687\\
l= & 10{\cdot}23
\end{array}$$

$$\text{Lateral surface}=3\times 2{\cdot}5\times 10{\cdot}23=76{\cdot}725\text{ sq. feet}$$

$$\begin{array}{rr}
\log a= & {\cdot}3979400\\
 & 2\\
\hline
 & {\cdot}7958800\\
\log n= & {\cdot}7781513\\
\text{L Cot }30^\circ= & 10{\cdot}2385606\\
\text{colog }4= & 9{\cdot}3979400\\
\hline
\text{Log area of base}= & 1{\cdot}2105319
\end{array}
\qquad
\begin{array}{rl}
\text{area of base}= & 16{\cdot}238\\
\hline
\text{whole surf.}= & 92{\cdot}963\text{ sq. feet}\\
\hline
\text{log base}= & 1{\cdot}2105319\\
\log h= & 1{\cdot}0000000\\
\text{colog }3= & 9{\cdot}5228787\\
\hline
\text{log volume}= & 1{\cdot}7334106\\
\text{volume}= & 54{\cdot}126\text{ cubic feet.}
\end{array}$$

38. *To find the Volume of the Frustum of any Pyramid.*—Let the pyramid ACF be cut by a plane abc parallel to the base ABC, and let AB = a_1, $ab=a_2$; the areas ACB = m_1^2, $acb=m_2^2$; the heights FG = h_1, FH = h_2, GH = h. Then the frustum AcB

= pyramid ACF − pyramid abc

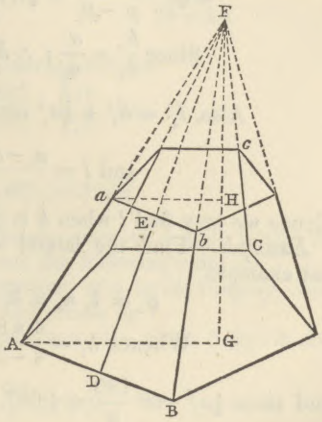
$$=\tfrac{1}{3}m_1^2h_1-\tfrac{1}{3}m_2^2h_2\ \text{(art. 35)}.$$

$$\text{But }\frac{h_1}{h_2}=\frac{\text{AF}}{a\text{F}}=\frac{a_1}{a_2};$$

$$\therefore\ \frac{h_1}{h}=\frac{a_1}{a_1-a_2}=\frac{m_1}{m_1-m_2}.$$

$$\text{Hence }h_1=\frac{m_1h}{m_1-m_2},$$

$$\text{and }h_2=\frac{m_2h}{m_1-m_2}.$$



Therefore the volume of the frustum

$$=\tfrac{1}{3}h\cdot\frac{m_1^3-m_2^3}{m_1-m_2}=\tfrac{1}{3}h(m_1^2+m_1m_2+m_2^2);$$

a formula which applies to the frusta of all pyramids whether *right* or *oblique.*

39. The formula of article 38 may be put into a somewhat different form.—If AB = a_1, $ab=a_3$; area AC = m_1^2, area $ac=m_3^2$; and if a_2 m_2^2 be the side and area of the *middle section* of the frustum formed by a plane parallel to, and equidistant from, the planes AC, ac, we shall evidently have (*Euc.* vi. 20, cor. 3)—

$$m_1^2=c^2a_1^2,\ m_2^2=c^2a_2^2,\ m_3^2=c^2a_3^2;$$

where c depends on the nature of the polygon AD.

$$\text{Also } a_2=\tfrac{1}{2}(a_1+a_3);$$

$$\text{therefore } 4m_2^2=c^2(a_1+a_3)^2=c^2a_1^2+2c^2a_1a_3+c^2a_3^2$$
$$=m_1^2+2m_1m_3+m_3^2.$$

Now the volume of the frustum

$$=\tfrac{1}{6}h(2m_1^2+2m_1m_3+2m_3^2)^2\ \text{(art. 37)}.$$

Whence substituting

$$\text{the volume}=\tfrac{1}{6}h\,(m_1^2+4m_2^2+m_3^2);$$

or the volume of the frustum of a pyramid is obtained by adding the areas of the ends to four times the area of the *middle section, and multiplying the sum by one-sixth of the height.*

Example.—Find the volume of the frustum of an hexagonal pyramid, the sides of whose terminating polygons are 4 and 3 feet, and its height 9 feet.

(i.) By the formula of article 38.—By art. 22 we find $m_1^2 = 41{\cdot}569$, and $m_2^2 = 23{\cdot}383$.

$$\text{Whence } m_1 m_2 = 31{\cdot}177\,;$$
$$\text{and the volume } = 3\,(41{\cdot}569 + 31{\cdot}177 + 23{\cdot}383)$$
$$= 288{\cdot}39 \text{ cubic feet.}$$

(ii.) By the formula of article 39.—The side of the middle section, $a_2 = \frac{1}{2}(4+3) = 3{\cdot}5$.

Whence (art. 22) $m_2^2 = 31{\cdot}826$;

$$\text{and the volume } = \tfrac{3}{2}(41{\cdot}569 + 127{\cdot}304 + 23{\cdot}383)$$
$$= 288{\cdot}39 \text{ cubic feet.}$$

40. *To find the Surface of the Frustum of a Right Pyramid.*—In fig. art. 38 let the perimeter of AC $= p_1$, and that of $ac = p_2$; and the slant heights DF $= l_1$, EF $= l_2$, DE $= l$, AB $= a_1$, $ab = a_2$; then the lateral surface of the frustum is equal to the difference of the lateral surfaces of the pyramids AFC, $afc = \frac{1}{2}p_1 l_1 - \frac{1}{2}p_2 l_2$.

$$\text{But } \frac{l_1}{l_2} = \frac{a_1}{a_2}. \quad \therefore \frac{l_1}{l} = \frac{a_1}{a_1 - a_2} = \frac{p_1}{p_1 - p_2}.$$

$$\text{Hence } l_1 = \frac{p_1 l}{p_1 - p_2}, \text{ and } l_2 = \frac{p_2 l}{p_1 - p_2}\,;$$

Therefore the lateral surface of the frustum

$$= \tfrac{1}{2}l \cdot \frac{p_1^2 - p_2^2}{p_1 - p_2} = \tfrac{1}{2}l(p_1 + p_2).$$

$$\text{Since } \frac{h_1}{h_2} = \frac{a_1}{a_2}\,; \; \therefore h_1 = \frac{a_1 h}{a_1 - a_2}.$$

$$\text{Also, } l_1^2 = h_1^2 + \tfrac{1}{4}a_1^2 \cot^2 \frac{180^\circ}{n} \text{ (art. 37)};$$

$$\text{and } l = \frac{a_1 - a_2}{a_1} l_1.$$

Hence we may find l when h is given.

Example.—Find the lateral surface of the frustum in last example.

$$a_1 = 4,\; a_2 = 3,\; h = 9.$$

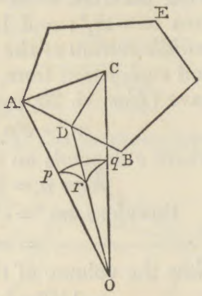
$$\text{Whence } h_1 = \frac{4 \times 9}{4 - 3} = 36\,;$$

and since $\frac{1}{4}a_1^2 \cot^2 \frac{180}{n} = 4{\cdot}687$, we have

$$l_1 = 36{\cdot}07, \text{ and } l = \frac{(4-3) \times 36{\cdot}07}{4} = 9{\cdot}0175.$$

Hence lateral surface $= 3(4+3) \times 9{\cdot}0175 = 189{\cdot}37$ square feet.

41. *To find the Volume and Surface of a Regular Polyhedron.*—Regular polyhedrons are solids contained by planes, which are equal, similar, and regular polygons; each solid angle of the polyhedron is contained by the same number of planes, having the same inclinations, and the polyhedron admits of having a sphere inscribed within it, or described about it. There are only five regular polyhedrons, which are enumerated in Table II.



Let ABE be one of the faces of the polyhedron, O the centre of a circumscribed sphere, and OC, OD perpendiculars to the plane ABE and to the line AB: then it is evident that AO and OC are the radii of spheres described about the polyhedron, and inscribed within it; that AB is bisected in D, and that C is the centre of the polygon ABE.

If l = the number of faces in the polyhedron,
m = the number of faces in each of its solid angles,
n = the number of sides in each of its faces, and
a = AB, the length of each of those sides;

and if we suppose the planes ACO, ADO, CDO, to meet the surface of a sphere whose centre is O in the arcs pq, pr, qr,

$$\text{the angles, } p = \frac{\pi}{m},\; q = \frac{\pi}{n},\; r = \frac{\pi}{2}\,;$$

and in the spherical triangle pqr,

$$\cos \text{AOC} = \cot p \cot q = \cot \frac{\pi}{m} \cot \frac{\pi}{n}$$

$$\text{whence } \cot \text{AOC} = \frac{\cos \frac{\pi}{m} \cos \frac{\pi}{n}}{\left\{ -\cos\left(\frac{\pi}{m} + \frac{\pi}{n}\right) \cos\left(\frac{\pi}{m} - \frac{\pi}{n}\right) \right\}^{\frac{1}{2}}}$$

Also CO = AC cot AOC = AD cosec ACD cot AOC,

$$= \tfrac{1}{2}a \operatorname{cosec} \frac{\pi}{n} \cot \text{AOC}\,;$$

$$\text{and the polygon ABE} = \frac{na^2}{4} \cot \frac{\pi}{n} \text{ (art. 22).}$$

Now, as the polyhedron is made up of l equal pyramids, whose bases and altitudes are respectively the same as the polygon ABE and the line CO,

$$\text{its volume} = \tfrac{1}{3}l \cdot \text{CO} \cdot \text{AEB (art 35.)},$$

$$= \frac{nla^3}{24} \cdot \frac{\cos \frac{\pi}{m} \cdot \cot^2 \frac{\pi}{n}}{\left\{ -\cos\left(\frac{\pi}{m} + \frac{\pi}{n}\right) \cos\left(\frac{\pi}{m} - \frac{\pi}{n}\right) \right\}^{\frac{1}{2}}} :$$

a form apparently impossible, but not really so; for in every polyhedron $\cos\left(\frac{\pi}{m} + \frac{\pi}{n}\right)$ is negative, the angle $\frac{\pi}{m} + \frac{\pi}{n}$ being $> 90^\circ$ and $< 180^\circ$.

It is evident (art. 22) that the surface

$$= \frac{lna^2}{4} \cdot \cot \frac{\pi}{n}.$$

Example.—Find the volume of a tetrahedron whose edge is 1.

The tetrahedron is contained by 4 equilateral triangles and each of its solid angles has 3 faces; whence

$$a = 1,\; m = 3,\; n = 3,\; l = 4$$

$$\therefore \frac{\pi}{m} = \frac{\pi}{n} = 60^\circ.$$

$$\text{Hence the volume } = \frac{4 \times 3}{24} \cdot \frac{\cos 60^\circ \cot^2 60^\circ}{(-\cos 120^\circ)^{\frac{1}{2}}}.$$

$$= \tfrac{1}{2} \cdot \frac{\frac{1}{2} \times \frac{1}{3}}{\frac{1}{\sqrt{2}}} = \cdot 1178513\,;$$

$$\text{and the surface} = \frac{3 \cdot 4}{4} \cot 60^\circ$$
$$= \sqrt{3} = 1{\cdot}7320508.$$

42. It obviously follows from the formulæ of last article, that the surface and volume of a polyhedron whose edge is a, may be obtained by multiplying the surface and volume of a similar polyhedron, whose edge is 1, by a^2 and a^3 respectively. The surfaces and volumes of the five regular polyhedrons, whose edges = 1, are given in table II.

Example.—Find the surface and volume of a regular dodecahedron whose edge is 5.

The tabular surface and volume from table II. are 20·6457788 and 7·6631189.

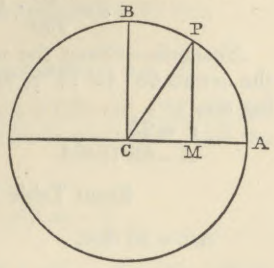
The surface $= 25 \times 20{\cdot}6457788 = 516{\cdot}14447$.
The volume $= 125 \times 7{\cdot}6631189 = 957{\cdot}88986$.

Mensuration.

SECTION III.—THE CIRCLE.

The Circumference of a Circle.

43. If CP$=r$, CN$=x$, MP$=y$, the equation to the circle is $x^2+y^2=r^2$;



$$\therefore \frac{dy}{dx}=-\frac{x}{y},$$

and the length of the arc AP

$$=\int_0^x\left(1+\frac{dy^2}{dx^2}\right)^{\frac{1}{2}}dx$$

$$=r\int_0^x\frac{dx}{(r^2-x^2)^{\frac{1}{2}}}$$

$$=r\left(\frac{x}{r}+\tfrac{1}{2}\cdot\frac{x^3}{3r^3}+\frac{1\cdot3}{2\cdot4}\cdot\frac{x^5}{5r^5}+\&c.\right)$$

Putting $x=r$, the length of the quadrant AP

$$=r\left(1+\frac{1}{2\cdot3}+\frac{1\cdot3}{2\cdot4\cdot5}+\frac{1\cdot3\cdot5}{2\cdot4\cdot6\cdot7}+\&c.\right)$$

44. A very rapidly converging series for the circumference of a circle is obtained by the following process.

It is shown in Trigonometry, that

$$\tan^{-1}m+\tan^{-1}n=\tan^{-1}\frac{m-n}{1+mn};$$

$$\therefore \tan^{-1}1-\tan^{-1}\frac{1}{5}=\tan^{-1}\frac{1-\frac{1}{5}}{1+\frac{1}{5}}=\tan^{-1}\frac{2}{3}$$

$$\tan^{-1}\frac{2}{3}-\tan^{-1}\frac{1}{5}=\tan^{-1}\frac{\frac{2}{3}-\frac{1}{5}}{1+\frac{2}{15}}=\tan^{-1}\frac{7}{17}$$

$$\tan^{-1}\frac{7}{17}-\tan^{-1}\frac{1}{5}=\tan^{-1}\frac{\frac{7}{17}-\frac{1}{5}}{1+\frac{7}{85}}=\tan^{-1}\frac{9}{46}$$

$$\tan^{-1}\frac{9}{46}-\tan^{-1}\frac{1}{5}=\tan^{-1}\frac{\frac{9}{46}-\frac{1}{5}}{1+\frac{9}{230}}=\tan^{-1}\frac{-1}{239}$$

Whence, adding,

$$\tan^{-1}1-4\tan^{-1}\frac{1}{5}=\tan^{-1}\frac{-1}{239},$$

$$\text{or}\quad\frac{\pi}{4}=4\tan^{-1}\frac{1}{5}-\tan^{-1}\frac{1}{239};$$

for $\tan^{-1}1=\frac{\pi}{4}$; where π is the circumference of a circle whose diameter is *unity*.

Now, it is proved in Trigonometry that

$$\tan^{-1}x=x-\tfrac{1}{3}x^3+\tfrac{1}{5}x^5-\tfrac{1}{7}x^7+\&c.$$

Therefore,

$$\frac{\pi}{4}=4\left(\frac{1}{5}-\frac{1}{3}\cdot\frac{1}{5^3}+\frac{1}{5}\cdot\frac{1}{5^5}-\frac{1}{7}\cdot\frac{1}{5^7}+\frac{1}{9}\cdot\frac{1}{5^9}-\&c.\right)$$
$$-\left(\frac{1}{239}-\frac{1}{3}\cdot\frac{1}{239^3}+\&c.\right);$$

a rapidly converging series, from which the value of π is calculated as follows:—

$$\begin{array}{rr@{\qquad}rr}
\frac{1}{5}= & \cdot200000000 & -\frac{1}{3}\cdot\frac{1}{5^3}= & -\cdot002666666 \\
\frac{1}{5}\cdot\frac{1}{5^5}= & \cdot000064000 & -\frac{1}{7}\cdot\frac{1}{5^7}= & -\cdot000001828 \\
\cline{4-4}
\frac{1}{9}\cdot\frac{1}{5^9}= & \cdot000000057 & & -\cdot002668494 \\
\cline{2-2}
 & \cdot200064057 & & \\
 & -\cdot002668494 & -\frac{1}{239}= & -\cdot004184100 \\
\cline{2-2}
 & \cdot197395563 & \frac{1}{3}\cdot\frac{1}{239^3}= & \cdot000000024 \\
\cline{4-4}
 & 4 & & -\cdot004184076 \\
\cline{2-2}
 & \cdot789582252 & & \\
 & -\cdot004184076 & & \\
\cline{2-2}
\frac{\pi}{4}= & \cdot785398176 & & \\
 & 4 & & \\
\cline{2-2}
\pi= & 3\cdot141592704, & &
\end{array}$$

which is correct to 7 places.

Mensuration.

The value of π to 20 places of decimals is

3·14159265358979323846.

The functions of π, which are most frequently useful in Mensuration, will be found in Table III.

45. Since π is the circumference of a circle whose diameter is unity; and since the circumference of circles are proportional to their radii, or to their diameters. (See TRIGONOMETRY.)

therefore if r = the radius; d=the diameter;
the circumference of the circle$=\pi d=2\pi r$.

Whence the following rules:—

(i.) *To find the circumference of a circle*, multiply the diameter, or twice the radius, by 3·14159..., or 3·1416.

Example 1.—The circumference of a circle whose diameter is 5 feet

$$=5\times3\cdot1415927=15\cdot7079635 \text{ feet.}$$

Example 2.—Find the circumference of the earth at the equator, the equatorial diameter being 7925·6 miles.

$$\begin{array}{rr}
\text{Log } 7925\cdot6= & 3\cdot8990321 \\
\log \pi= & \cdot4971499 \\
\cline{2-2}
\text{Circumference} = 24899\cdot0 \text{ miles.} & 4\cdot3961820
\end{array}$$

46. If we convert the value of π into a continued fraction we obtain

$$\frac{314159}{100000}=3+\cfrac{1}{7+\cfrac{1}{15+\cfrac{1}{1+\cfrac{1}{25+\&c.}}}}$$

Of which the successive convergents are

$$\frac{22}{7},\quad\frac{333}{106},\quad\frac{355}{113},\ \&c.$$

Of these

$$\frac{355}{113}=3\cdot1415929,$$

which differs from the accurate value of π only in the 7th place of decimals. Whence the following rules:—

(ii.) *To find the circumference of a circle roughly, multiply the diameter by* 22, *and divide by* 7.

Example.—The circumference of a circle 5 feet in diameter is about

$$5\times\frac{22}{7}-15\cdot71;$$

which is correct only in one place of decimals.

(iii.) *To find the circumference of a circle very nearly, multiply the diameter by* 355, *and divide by* 113.

Example.—The circumference of a circle whose diameter is 5 is

$$\frac{5\times355}{113}=15\cdot7079645;$$

a result correct in 5 places of decimals.

(iv.) *To multiply by π. Multiply by* 22 *and divide by* 7, *and from the result subtract $\frac{1}{8}$th of $\frac{1}{100}$th of the multiplicand.*—The result is too great by about its 200,000th part.

Example.—Find the circumference in last example.

$$\begin{array}{rr@{\qquad}l}
 & 5 & 100)\,5 \\
 & 22 & 8)\cdot05 \\
\cline{2-2}
 & 7)\,110 & \quad\cdot00625 \\
\cline{2-2}
 & 15\cdot714285 & \\
 & 006250 & \\
\cline{2-2}
\text{Circumference}= & 15\cdot708035 &
\end{array}$$

47. *To find the diameter of a Circle when the Circumference is given.*

(i.) It follows from article 45, that *to find the diameter we must divide the circumference* by 3·14159, or multiply by ·31830986184.

Or if c = the circumference of the circle,

$$d=\frac{c}{\pi};\quad r=\frac{c}{2\pi}.$$

Example.—The diameter of the circle whose circumference is 15·70796

$$=15{\cdot}70796\times{\cdot}3183098=4{\cdot}999998=5\text{ nearly.}$$

(ii.) *To find the diameter roughly, multiply the circumference by* 7, *and divide by* 22.

(iii.) *To find the diameter nearly, multiply the circumference by* 113, *and divide by* 355.

(iv.) *To divide by* π, *multiply by* 7, *divide by* 11 *and by* 2, *and to the result add* $\frac{1}{8}$*th of* $\frac{1}{1000}$*th of the dividend.* The result is too small by about its 100,000th part.

Example.—Find the diameter in last example.

$$\begin{array}{r} 15{\cdot}707964 \\ 7 \\ \hline 11)\overline{109{\cdot}955748} \\ \hline 2)\overline{9{\cdot}995977} \\ \hline 4{\cdot}997989 \\ {\cdot}001964 \\ \hline 4{\cdot}999953 \end{array}=\text{the diameter.}\qquad \begin{array}{r} 1000)\overline{15{\cdot}707964} \\ 8)\overline{{\cdot}015708} \\ \hline {\cdot}001964 \end{array}$$

Arcs of Circles.

48. Since angles at the centres of circles are proportional to the arcs on which they stand (GEOM. sec. iv., theor. 31; or *Euc.* vi. 33),

if A = the number of degrees in the angle at the centre;
r = the radius,
a = the arc which subtends the angle A,

$$\pi r : a :: 180^\circ : \mathrm{A};$$

$$\therefore\ \mathrm{A}=\frac{180^\circ}{\pi}\cdot\frac{a}{r};$$

$$\text{or }\mathrm{A}=57{\cdot}2957795\times\frac{a}{r}.$$

From this equation the following rules are obtained:—

49. (i.) *To find the number of degrees in an arc when its length and the radius of the circle are given, multiply the length of the arc by* 57·29578, *and divide by the radius.*

Example.—If the radius of a circle be 25 and the arc 30, the number of degrees in the arc

$$=57{\cdot}29578\times\frac{30}{25}=68^\circ{\cdot}75494=68^\circ\ 45'\ 17''{\cdot}8;$$

or, by logarithms,

$$\begin{array}{rl} \text{From Table III. } \log\frac{180}{\pi} & =1{\cdot}7581226 \\ a=30\quad \log a & =1{\cdot}4771213 \\ r=25\quad \text{colog } r & =8{\cdot}6020600 \\ \hline \mathrm{A}=68^\circ{\cdot}75494\qquad \log \mathrm{A} & =1{\cdot}8373039 \\ =68^\circ\ 45'\ 17''{\cdot}8. & \end{array}$$

50. (ii.) *To find the radius of the circle when the length of the arc and the number of degrees which it contains are given, multiply the length of the arc by* 57·29578, *and divide by the number of degrees in the angle.*

For, by the formula (art. 48.),

$$r=57{\cdot}2957795\times\frac{a}{\mathrm{A}}.$$

Example.—The length of the arc is 30 feet, and the angle, which it subtends at the centre, 68° 45′ 17″·8. Find the radius of the circle.

$$\begin{array}{ll} a=30 & \log\frac{180}{\pi}=1{\cdot}7581226 \\ \mathrm{A}=68^\circ\ 45'\ 17''{\cdot}8 & \log a\ \ =1{\cdot}4771213 \\ \quad =68{\cdot}75494 & \text{colog}\,\mathrm{A}=8{\cdot}1626961 \\ & \log r\ \ =\overline{1{\cdot}3989400} \end{array}$$

Hence the radius = 25 feet.

51. (iii.) *To find the arc when the radius and the angle subtended at the centre are given, multiply the number of degrees in the angle by the radius and by* ·0174533. For, by the formula of art. 48,

$$a=\frac{\pi}{180}\cdot \mathrm{A}r={\cdot}0174533\times \mathrm{A}r.$$

Example.—Given the radius 25 feet, and the angle at the centre 68° 45′ 17″·8, to find the length of the subtending arc.

$$\begin{array}{lrl} r\ =25 & \log r & =1{\cdot}3979400 \\ \mathrm{A}-68{\cdot}75494 & \log \mathrm{A} & =1{\cdot}8373039 \\ & \text{From Table III. }\log\frac{\pi}{180} & =\bar{2}{\cdot}2418774 \\ \text{Arc}=30\text{ feet.} & \log a & =\overline{1{\cdot}4771213} \end{array}$$

Since the length of an arc $=\frac{\pi \mathrm{A}}{180}\times$ radius; if $\frac{\pi \mathrm{A}}{180}$ (or the length of an arc to radius = 1) be computed for the various values of A, and arranged in a table (See Table IV.), the length of any arc may be found by multiplying the proper tabular number by the radius of the arc.

Example.—To find the length of an arc whose radius is 25, and angle 68° 45′ 17″·8.

$$\begin{array}{rr} \text{From Table IV. arc of }60^\circ= & 1{\cdot}0471976 \\ 8^\circ= & {\cdot}1396263 \\ 40'= & 116355 \\ 5'= & 14544 \\ 10''= & 485 \\ 7''= & 339 \\ 0''{\cdot}8= & 39 \\ \hline & 1{\cdot}2000001 \end{array}$$

∴ Arc to radius 25 = 1·2 × 25 = 30.

A great variety of problems in finding the lengths of arcs may be proposed. The following seem to be the most important:—

52. (iv.) *To find the length of an arc whose chord and radius are given.*—In fig. art. 22 we have given AC = r, AB = $2c$.

To find the length of the arc AEB. Put the angle ACB = A, then $\sin\frac{\mathrm{A}}{2}=\frac{c}{r}$; whence A is known, and the length of the arc is found by art. 51.

Example.—The chord of an arc is 28·23214 feet, and the radius 25 feet. Find the length of the arc.

$$\begin{array}{ll} \text{Here } c=14{\cdot}11607 & \log c\ \ =1{\cdot}1497136 \\ \quad r=25 & \log r\ \ =\underline{1{\cdot}3979400} \\ \therefore\ \frac{\mathrm{A}}{2}=34^\circ\ 22'\ 38''{\cdot}9 & \text{L}\sin\frac{\mathrm{A}}{2}=9{\cdot}7517736 \\ \text{and }\mathrm{A}=68^\circ\ 45'\ 17''{\cdot}8 & \end{array}$$

Having ascertained A, we find, by art. 51, that the length of the arc is 30 feet.

53. *To find the Length of an Arc when its Chord, and Height, or Versed Sine, are given.*—In fig. art. 22, putting DE = h;

$$\because\ \mathrm{AC}^2=\mathrm{AD}^2+\mathrm{CD}^2;\ \therefore\ r^2=c^2+(r-h)^2:$$

$$\text{Hence } r=\tfrac{1}{2}\left(h+\frac{c^2}{h}.\right)$$

The radius r being known, the length of the arc is found by art. 52.

Example.—Given the chord of an arc 28·23214 feet, and its versed sine 4·36661, to find its length.

$$\begin{array}{ll} c\ =14{\cdot}11607 & \log c=1{\cdot}1497136 \\ & \qquad\qquad\quad 2 \\ & \log c^2=2{\cdot}2994272 \\ h=\ 4{\cdot}3666 & \log h=\ {\cdot}6401444 \\ \frac{c^2}{h}=45{\cdot}6334 & \log\frac{c^2}{h}=1{\cdot}6592828 \\ \hline 50{\cdot}0000 & \end{array}$$

The radius r = 25·0.

Mensuration.

We have now $\sin A = \frac{c}{r}$ (art. 52),

whence $A = 68°·75494$;

and finally, by art. 52, the arc is found to be 30 feet.

The Area of a Circle.

54. In the figure to article 43, if $CP = r^2$, $CM = x$, and $MP = y$, the equation to the circle is $x^2 + y^2 = r^2$, and the area of the quadrant ABC.

$$= \int_0^r y dx = \int_0^r (r^2 - x^2)^{\frac{1}{2}} dx = \frac{\pi r^2}{4}$$

Whence the area of the circle $= \pi r^2$. See also article 59.

55. A more elementary demonstration may be obtained as follows:—

The area of a circle is greater than that of any inscribed, and less than that of any circumscribed polygon; and by continually increasing the number of sides of the polygons, their areas will obviously approach to equality with each other, and with that of the circle.

Let AB, FG (fig. art. 22) be the sides of regular inscribed and circumscribed polygons,

n = the number of sides in each,
P = the area of the circumscribed polygon,
p = the area of the inscribed polygon.

Then putting θ for the angle ACB,

$$\theta = \frac{\pi}{n};$$

and, by continually increasing n, θ diminishes indefinitely, and ultimately

$$\frac{\tan \theta}{\theta} = \frac{\sin \theta}{\theta} = 1. \text{ (See TRIGONOMETRY.)}$$

$$\text{Now, } P = nr^2 \tan \frac{\pi}{n} = \pi r^2 \cdot \frac{\tan \frac{\pi}{n}}{\frac{\pi}{n}} \quad \text{(art. 25.)}$$

$$= \pi r^2 \cdot \frac{\tan \theta}{\theta} = \pi r^2 \text{ ultimately;}$$

$$\text{for } \frac{\tan \theta}{\theta} = 1 \text{ ultimately.}$$

$$\text{Also } p = nr^2 \sin \frac{\pi}{n} \cos \frac{\pi}{n} = \pi r^2 \cdot \frac{\sin \frac{\pi}{n}}{\frac{\pi}{r}} \cdot \cos \frac{\pi}{n} \quad \text{(art. 24.)}$$

$$= \pi r^2 \frac{\sin \theta}{\theta} \cdot \cos \theta = \pi r^2 \text{ ultimately;}$$

$$\text{for } \frac{\sin \theta}{\theta} = 1 \text{ and } \cos \theta = 1 \text{ ultimately.}$$

Therefore, since we have always

$$P > \text{area of circle} > p;$$

and since P and p both ultimately differ from πr^2 by less than any assignable quantity, it follows that

the area of the circle $= \pi r^2$.

56. If d be the diameter of the circle,

$$d = 2r, \text{ and area} = \frac{\pi}{4} d^2;$$

where $\frac{\pi}{4} = ·785398163397$,

again the area $= \pi r \cdot r$.

But if c = the circumference, $c = 2\pi r$,

therefore the area $= \frac{1}{2} cr = \frac{1}{2} c \times \frac{1}{2} d$.

Mensuration.

Lastly, the area $= \pi r^2 = \frac{4 \pi^2 r^2}{4 \pi} = \frac{c^2}{4 \pi}$,

where $\frac{1}{4 \pi} = ·07957747155$.

Whence the following rules:—

(i.) *The area of a circle is obtained by multiplying the square of the radius by* 3·14159.

Example.—The area of a circle whose radius is 3·5,

$$= (3·5)^2 \times 3·14159 = 12·25 \times 3·14159 = 38·4845.$$

(ii.) *The area of a circle is equal to the square of the diameter multiplied by* ·785398.

Example.—The area of a circle whose diameter is 7,

$$= 49 \times ·785398 = 38·4845.$$

(iii.) *The area of a circle is equal to half the diameter multiplied by half the circumference.*

Example.—The diameter of a circle is 7; find the area. By article 45, the circumference $= 21·9911486$;

therefore the area $= 3·5 \times 10·9955743 = 38·4845$.

(iv.) The area of a circle is equal to the square of the circumference multiplied by ·0795575.

Example.—The circumference being 21·9911486;

the area $= (21·9911486)^2 \times ·0795575 = 38·4845$.

57. In the formulæ of articles 55 and 56, if we put

C^2 = the area of the circle,

$$r = \frac{1}{\sqrt{\pi}} \cdot C \quad \text{where } \frac{1}{\sqrt{\pi}} = ·5641896$$

$$d = \frac{2}{\sqrt{\pi}} \cdot C \quad \text{where } \frac{2}{\sqrt{\pi}} = 1·1283792$$

$$c = 2\sqrt{\pi} \cdot C \quad \text{where } 2\sqrt{\pi} = 3·5449077.$$

Whence, to find the radius, diameter, or circumference of a circle when the area is given, multiply the square root of the area by ·5641896, 1·1283792, or 3·5449077 *respectively*

Example.—The area of a circle is 38·4845.

$\sqrt{38·4845} = 6·2036$
$\therefore$ radius $= 6·2036 \times ·5641896 = 3·5$
diameter $= 6·2036 \times 1·1283792 = 7·0$
circumference $= 6·2036 \times 3·5449077 = 21·9911$.

58. *To find the Area of a Circular Ring.*—The ring is a plane surface bounded by two circles, described one within the other, but not necessarily concentric. If r_1, r_2 be the outer and inner radii of the ring, its area

$$= \pi (r_1^2 - r_2^2) = \pi (r_1 + r_2)(r_1 - r_2).$$

Example.—Find the area of a ring whose outer and inner diameters are 10 and 6.

$$r_1 = 5 \text{ and } r_2 = 3;$$

$$\therefore \text{area} = 8 \times 2 \times 3·14159 = 50·2655.$$

59. *To find the Area of a Sector of a Circle.*—If r be the radius of the circle (fig. art. 43), and θ the angle ACP, then the area of the sector ACP

$$= \frac{1}{2} r^2 \int_0^\theta d\theta = \frac{1}{2} \theta r^2 = \frac{1}{2} \text{ arc} \times \text{radius}.$$

For the whole circle $\theta = 2\pi$;

$$\therefore \text{circle} = \pi r^2,$$

as was already proved in articles 54 and 55.

Or, since sectors have the same ratio as the arcs on which they stand (*Euclid* 33, vi.), if A = the angle of the sector, in degrees,

$$360° : A :: \text{area of circle} : \text{area of sector};$$

$$\therefore \text{sector} = \frac{A}{360} \pi r^2.$$

Mensuration.

Again, since $\frac{A}{360}=\frac{a}{2\pi r}$ (art. 48),

$$\text{the sector}=\tfrac{1}{2}ar;$$

and, finally, since $\theta=\frac{a}{r}$,

$$\text{the sector}=\tfrac{1}{2}\theta r^2.$$

We have therefore the following rules:—

(i.) *The area of a sector is equal to the area of the whole circle, multiplied by the number of degrees in the arc of the sector, and divided by* 360.

Example.—The radius of a sector is 25 feet, and its angle 68° 45′ 17″·8. Required its area.

Here $r=25$, $A=68·75494$;

$$\therefore \text{area of sector}=\frac{(25)^2\times 3·14159\times 68·75494}{360}=375 \text{ sq. ft.}$$

Or, by logarithms,

$\log r=1·3979400$
2
$2·7958800$
$\log \pi=\ ·4971499$
$\log A=1·8373039$
$\text{colog } 360=7·4436975$
$\log \text{area}=2·5740313$

Area $=375$.

Since, by art. 63, a sector

$$=\frac{A}{360}\pi r^2=\tfrac{1}{2}\times\frac{A\pi}{180}\times r^2;$$

where $\frac{A\pi}{180}=$ the length an arc of A° to radius 1, its area will be found by ascertaining the value of $\frac{A\pi}{180}$ from Table IV., and multiplying by the square of the radius.

Example.—To find the sector whose radius is 25 and angle 68° 45′ 17″·8.

From Table II. (see art. 51).—The length of an arc of 68° 45′ 17″·8 to radius $1=1·2$;

$$\therefore \text{area of sector}=1·2\times(25)^2=1·2\times 625=375.$$

(ii.) *The area of a sector is equal to one-half of the length of its arc multiplied by its radius.*

Example.—If the radius of a sector be 25 feet, and the length of its arc 30 feet,

$$\text{its area}=\tfrac{1}{2}\times 30\times 25=375 \text{ square feet.}$$

(iii.) If the radius AC and chord AB (fig. art. 22) be given, putting $AC=r$, $AB=2c$,

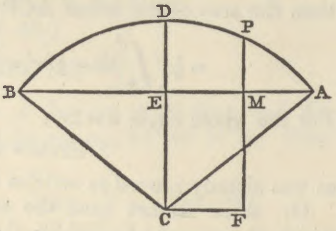
$$\text{we have } \sin\frac{A}{2}=\frac{c}{r},$$

whence A is known; and the area of the sector is found by Rule (i.)

Example.—If the radius of a sector is 25, and the chord of its arc 28·23214, what is its area?

Here A is ascertained to be 68° 45′ 17″·8 (see art. 52); and by Rule (i.) the area of the sector is found to be 375.

60. *To find the Area of a Segment of a Circle.*—Let C be the centre of the circle, $CD=r$, $DE=a$, $MP=b$, $CE=c$, $EM=h$, $AE=l$. Then, if $EM=x$, and $MP=y$,



$$(y+c)^2+x^2=r^2,$$

and the area DEMP

$$=\int_0^h y\,dx=\int_0^h (r^2-h^2)^{\frac{1}{2}}dx,$$

$$=\frac{r^2}{2}\sin^{-1}\frac{h}{r}+\frac{h}{2}(r^2-h^2)^{\frac{1}{2}}-ch.$$

Also the area $ADB=\int_{-l}^{+l} y\,dx$

$$=r^2\sin^{-1}\frac{l}{r}-cl=\text{sector } ACBD-\text{triangle } ABC.$$

Mensuration.

61. We may also express the areas DEMP, ADBE, in terms of AE, DE, and MP.

For, from the equation to the circle,

$$(b+c)^2+h^2=r^2\ (a+c)^2.$$

Whence $c=\frac{b^2+h^2-a^2}{2(a-b)}$, $r=\frac{(a-b)^2+h^2}{2(a-b)}$, and $(r^2-h^2)^{\frac{1}{2}}$

$$=b+c=\frac{h^2-(a-b)^2}{2(a-b)}.$$

Wherefore, substituting area DEMP

$$=\frac{1}{4(a-b)}\left\{\frac{[(a-b)^2+h^2]^2}{2(a-b)}\sin^{-1}\frac{2(a-b)h}{(a-b)^2+h^2}+(a^2+2ab-3b^2-h^2)h\right\}.$$

When $h=l$, $b=o$;

$$\therefore \text{area } ABD=\frac{1}{2a}\left\{\frac{(a^2+l^2)^2}{2a}\sin^{-1}\frac{2al}{a^2+l^2}-(l^2-a^2)\,l\right\}.$$

62. Again, since the area of the segment $ADB=$ sector $ADBC-$ triangle ABC; putting angle $ACB=\theta$, and $AC=r$,

$$\text{the segment}=\tfrac{1}{2}\theta r^2-\tfrac{1}{2}r^2\sin\theta \quad \text{(arts. 59 and 11)}$$
$$=\tfrac{1}{2}r^2(\theta-\sin\theta).$$

Whence (i.) *to find the area of a segment of a circle, find the area of the corresponding sector, and subtract the triangle contained by the radii of the sector and the base of the segment.*

Among various particular cases of this problem, the following may be noted:—

(ii.) *Given the radius* $AC=r$, *and the angle at the centre* $ACB=A°$.

$$\text{The sector } ADBC=\frac{A}{360}\pi r^2 \text{ (art. 59)};$$

$$\text{the triangle } ABC=\tfrac{1}{2}r^2\sin A;$$

$$\therefore \text{area of segment } ABD=\tfrac{1}{2}r^2\left(\frac{\pi A}{180}-\sin A.\right)$$

Example.—Find the area of the segment whose arc has a radius of 25 feet, and which subtends an angle of 68° 45′ 17″·8 at the centre.

$r=25$ $\log r=1·3979400$
2
$\log r^2=2·7958800$
$A=68°45'17''·8$ $L\sin A=9·9694343$
$\text{colog } 2=9·6989700$
$2·4642843$

Area of triangle 291·262.

In *Ex.* Rule (i.) (art. 59), the area of the sector has been found to be $=375·000$
the triangle $=291·262$
$\therefore$ segment $=\ 83·738$

(iii.) *Given the Chord and Radius of the Segment.*—Let $2c=$ the chord, $r=$ the radius, $A=$ angle at centre.

$$\text{Then } \sin\frac{A}{2}=\frac{c}{r};$$

and A being known, the area of the segment is found by Rule (ii.)

Example.—Find the area of the segment whose radius is 25, and chord 28·23214.

$c=14·11607$, from which $A=68°\ 45'\ 17''·8$ (see *Ex.* art. 52); and the area is then found, by Rule (ii.), to be 83·738.

(iv.) *Given the chord and height, or versed sine of the segment.*—Let $2c=$ the chord, $h=$ the height, $r=$ the radius.

$$r=\tfrac{1}{2}\left(h+\frac{c^2}{h}\right) \text{ (art. 53).}$$

Then A is found as in Rule (iii.), and finally the area is obtained by Rule (ii.)

Example.—Given the chord of a segment 28·23214, and its height 4·36661, to find its area.

$c=14·11607$ and $h=4·36661$, from which $r=25$ (see art. 53).

From r and c we have

$$A = 68° \ 45' \ 17''{\cdot}8 \text{ by Rule (iii.).}$$

Finally, from r and A we find by Rule (ii.) that

$$\text{the area } = 83{\cdot}738.$$

(v.) *Given the height and radius or diameter of the segment.*—Let $r =$ the radius, $h =$ the height, then, by (ii.),

$$\text{the area } = \tfrac{1}{2}\left(\frac{\pi A}{180} - \sin A\right) \times r^2;$$

and we have

$$\text{versin } A = \frac{h}{r}.$$

Whence A is known, and the area may be calculated as in (ii.).

If the radius be divided into n equal parts, and h be taken successively equal to $\frac{r}{n}$, $\frac{2r}{n}$, &c., the corresponding values of $\frac{h}{r}$, and of the factor $\tfrac{1}{2}\left(\frac{\pi A}{180} - \sin A\right)$ may be calculated and arranged in a table (see Table V.). *The area of any segment may then be ascertained by dividing its height by the radius of its arc, so as to obtain the tabular versed sine and the corresponding tabular number, and then multiplying the tabular number by the square of the radius of the segment.*

Example.—To find the area of a segment whose height is 4·36661, and whose radius is 25.

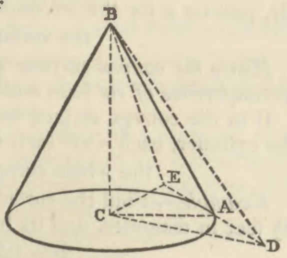
$$\text{Here } h = 4{\cdot}36661, \ d = 50.$$

$$\text{Tabular versin} = \frac{h}{r} = \frac{4{\cdot}36661}{25} = {\cdot}175 \text{ nearly.}$$

The tabular number for ·175, obtained by taking the mean of those for ·17 and ·18, is ·134396;

$$\therefore \text{ area of segment} = {\cdot}134396 \times (25)^2 = 84 \text{ nearly.}$$

The Cone.



63. *To find the Volume of a Right Cone.*—The right cone is generated by the revolution of a right-angled triangle ABC about its side BC.

Let BED be the side of a regular pyramid of n sides described about the cone, and put $AC = r$, $BC = h$.

Then the volume of the pyramid (art. 36)

$$= \tfrac{1}{3}n \cdot \text{CED} \cdot \text{BC} = \tfrac{1}{3}n \cdot \text{AC} \cdot \text{AD} \cdot \text{BC}$$

$$= \tfrac{1}{3}nr^2h \tan\frac{\pi}{n} = \tfrac{1}{3}\pi r^2 h \cdot \frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}}.$$

But by increasing n indefinitely,

$$\frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}} = 1 \text{ ultimately,}$$

and the pyramid becomes ultimately equal to the cone. Therefore the volume of the cone

$$= \pi r^2 h, \text{ or } = \tfrac{1}{3}m^2 h;$$

where m^2 is put for the area of the base of the cone.

Hence the volume of a cone is equal to one-third the product of the area of its base multiplied by its height.

Example.—Find the volume of the cone whose height is 13, and the radius of its base 3·5.

The area of the base $= 38{\cdot}4845$ (*Ex.* (i.) art. 56);

Therefore the volume $= \tfrac{1}{3} \times 13 \times 38{\cdot}4845 = 166{\cdot}77$.

64. *To find the Surface of a Right Cone.*—Putting $AB = l$, the lateral surface of the pyramid described about the cone,

$$= n\,\text{BED} = n\,\text{AB} \cdot \text{AD} = nlr \tan\frac{\pi}{n} = \pi lr \cdot \frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}}.$$

But by increasing n indefinitely,

$$\frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}} = 1;$$

and the surface of the pyramid coincides with that of the cone;

$$\therefore \text{ surface of cone } = \pi lr.$$

Also, if $p =$ the circumference of the base,

$$\therefore \pi lr = \tfrac{1}{2} \cdot 2\pi r \cdot l = \tfrac{1}{2}pl;$$

$$\therefore \text{ the convex surface } = \tfrac{1}{2}pl.$$

Hence the convex surface of a cone is equal to half the perimeter of the base multiplied by the slant height.

If we add the surface of the base, the whole surface,

$$= \pi r^2 + \pi lr$$

$$= \pi r(r + l).$$

Again, if $h =$ the vertical height,

$$l = (r^2 + h^2)^{\frac{1}{2}}$$

$$\therefore \text{ surface } = \pi r\{r + (r^2 + h^2)^{\frac{1}{2}}\}.$$

Example.—Find the surface of a cone whose height is 13, and the radius of its base 3·5,

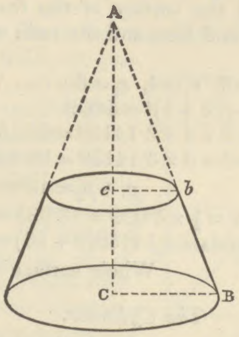
The slant height $l = (169 + 12{\cdot}25)^{\frac{1}{2}} = 13{\cdot}46$ nearly.

The convex surface $= 3{\cdot}14159 \times 3{\cdot}5 \times 13{\cdot}46 = 148{\cdot}0$

The surface of the base (art. 56) $= \ \ 38{\cdot}5$

The whole surface $= 186{\cdot}5$

65. *To find the Volume of the Frustum of a right Cone.*—The frustum is cut off by a plane parallel to the base.



Let the radii of the ends $BC = r_1$, $bc = r_2$, and the height $Cc = h$. Also, let $AC = h_1$, $Ac = h_2$.

$$\text{Then } \frac{h_1}{h_2} = \frac{r_1}{r_2}; \ \therefore \frac{h_1}{h} = \frac{r_1}{r_1 - r_2}.$$

$$\text{From which } h_1 = \frac{r_1 h}{r_1 - r_2}, \text{ and } h_2 = \frac{r_2 h}{r_1 - r_2}.$$

Since the frustum = difference of cones ABC, Abc,

$$\text{its volume } = \tfrac{1}{3}\pi r_1^2 h_1 - \tfrac{1}{3}\pi r_2^2 h_2 \text{ (art. 63)}$$

$$= \tfrac{1}{3}\pi h \cdot \frac{r_1^3 - r_2^3}{r_1 - r_2} = \tfrac{1}{3}\pi h(r_1^2 + r_1 r_2 + r_2^2).$$

Or if a_1^2, a_2^2 be the areas of the ends of the frustum,

$$\text{the volume} = \tfrac{1}{3}h(a_1^2 + a_1 a_2 + a_2^2).$$

66. It may also be shown, as in art. 39, that the volume

$$= \tfrac{1}{6}h(a_1^2 + 4a_2^2 + a_3^2).$$

Where a_1^2, a_3^2 are the areas of the terminating planes of the frustum, and a_2^2 the area of a section parallel to these planes, and equidistant from them.

Example.—Find the volume of the frustum of a cone, the radii of whose ends are 3 and 4 feet, and its height 5 feet.

log 3 = ·4771213
2
log $(3)^2$ = ·9542425
log π = ·4971499
log a_2^2 = 1·4513924

log 4 = ·6020600
2
log $(4)^2$ = 1·2041200
·4971499
log a_1^2 = 1·7012699
log a_2^2 = 1·4513924
2) 3·1526623
log a_1a_2 = 1·5763312

$a_1^2=50·266$
$a_2^2=28·274$
$a_1^2=37·699$
116·639

log = 2·0653519
log 5 = ·6989700
colog 3 = 9·5228787
Volume = 193·73. log volume = 2·2872006

67. *To find the Surface of the Frustum of a Cone.*—If the slant heights (fig. art. 65) AB, Ab, Bb, be l_1, l_2, and l respectively, it may be shown, as in last article, that

$$l_1=\frac{lr_1}{r_1-r_2},\text{ and } l_2=\frac{lr_2}{r_1-r_2};$$

and since the lateral surface of the frustum is equal to the difference of the lateral surfaces of the cones;

$$\therefore\text{ lateral surface}=\pi l_1r_1-\pi l_2r_2\text{ (art. 64)};$$

$$=\pi l\cdot\frac{r_1^{\,2}-r_2^{\,2}}{r_1-r_2}=\pi l(r_1+r_2).$$

Again, because the surface

$$=\tfrac{1}{2}l(2\pi r_1+2\pi r_2),$$

if p_1, p_2 be put for the perimeters of the ends,

$$\text{the lateral surface }=\tfrac{1}{2}l(p_1+p_2).$$

The whole surface is obtained by adding to the lateral surface the areas of the circles which form the ends of the frustum.

If the perpendicular height h be given, we have evidently

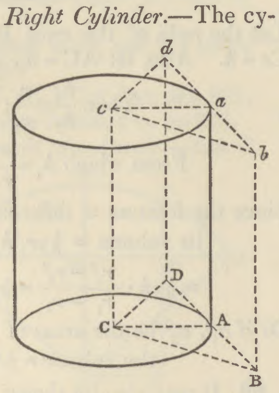
$$l=\{h+(r_1-r\quad\}^{\frac{1}{2}}.$$

Example.—Find the surface of the frustum of a right cone whose height is 5 feet, and the radii of its ends 3 and 4 feet.

Here $h=5$, $r_1=4$, $r_2=3$;
$\therefore l=(25+1)^{\frac{1}{2}}=5·099$
$p_1=2\times4\times3·14159=25·133$
$p_2=2\times3\times3·14159=18·850$
$p_1+p_2=43·983$
Convex surface $=\frac{1}{2}\times5·099\times43·983=112·13$
The areas of ends $=3·14159(9+16)=$ 78·54 (art. 56)
Whole surface = 190·67

The Cylinder.

68. *To find the Volume of a Right Cylinder.*—The cylinder is generated by the revolution of a rectangle ACca about its side Cc.



Let BDdb be the side of an equilateral prism of n sides described about the cylinder, and put AC $=r$. Then the base of the prism is a regular polygon of n sides whose area

$$=nr^2\tan\frac{\pi}{n}\text{ (art. 25.)}$$

Therefore the volume of the prism

$$=nr^2h\tan\frac{\pi}{n}=\pi r^2h\cdot\frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}}.$$

But when n is increased indefinitely, the prism evidently coincides with the cylinder,

$$\text{and }\frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}}=1;$$

$$\therefore\text{ the cylinder }=\pi r^2h.$$

Or if m^2 be put for the area of the base,

$$\text{the cylinder}=m^2h.$$

Hence the volume of a cylinder is equal to the area of its base multiplied by its height.

Example.—Find the volume of a cylinder whose base is $4\frac{1}{2}$ feet in diameter and its height 8 feet.

Here $r=2·25$, $h=8$.
log 2·25 = ·3521825
2
log $(2·25)^2$ = ·7043650
log π = ·4971499
log 8 = ·9030900
Volume = 127·235. log volume = 2·1046049

69. *To find the Surface of a Cylinder.*—The lateral surface of the prism in last article $=n\times$ parallelogram Bd,

$$=2n\cdot\text{AB}\cdot\text{A}a=2nhr\tan\frac{\pi}{n}=2\pi hr\cdot\frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}}.$$

But by indefinitely increasing n, the surface of the prism will coincide with that of the cylinder, and ultimately

$$\frac{\tan\frac{\pi}{n}}{\frac{\pi}{n}}=1;$$

$$\therefore\text{ convex surface of cylinder}=2\pi rh.$$

Or, putting p for the circumference of the base,

$$\text{the surface}=ph.$$

Hence the convex surface of a cylinder is equal to the circumference of its base multiplied by its height.

If to the convex surface we add the areas of the ends of the cylinder, each $=\pi r^2$ (art. 55), we obtain

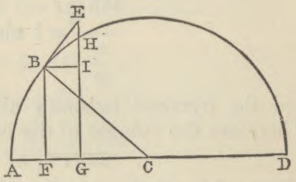
$$\text{the whole surface}=2\pi r(r+h).$$

Example.—Find the surface of a cylinder whose base is $4\frac{1}{2}$ feet in diameter, and its height is 8 feet.

$2r=4·5$, $h=8$.
log 4·5 = ·6532125   By art. 55,
log 8 = ·9030900   surface of ends = 31·808.
log π = ·4971499   convex surface = 113·098.
Log convex surface = 2·0534524   whole surface = 144·906.

The Sphere.

70. *To find the Surface of a Sphere or of a Spherical Segment or Zone.*—Let the sphere be generated by the revolution of the semicircle ABD round AD; and put AC $=r$, AF $=x$, BF $=y$. Then



$$y^2=2rx-x^2,\ \frac{dy}{dx}=\frac{r-x}{y};$$

and the surface generated by the revolution of the arc AB

$$=2\pi\int_0^x y\left(1+\frac{dy^2}{dx}\right)^{\frac{1}{2}}dx=2\pi\int_0^x rdx=2\pi rx.$$

Hence the convex surface of a segment whose height is h $=2\pi rh$.

Also, if AG $=a$, AF $=b$, FG $=h$, the surface of the zone generated by BH

$$=2\pi\int_b^a r\,dx=2\pi r(a-b)=2\pi rh:$$

and, if AD $=d$, the surface of the whole sphere

$$=2\pi\int_0^{2r} r\,dx=4\pi r^2=\pi d^2.$$

71. Otherwise: let BE be a tangent to the circle. Then if the figure revolves about AD, BH will describe a spherical, and BE a conical surface; and if EG be taken indefinitely near to BF, the two surfaces will ultimately be equal.

Let AC $=r$, and ACB $=\theta$.
Then BF $=r\sin\theta$, and BE $=$ FG $\operatorname{cosec}\theta$.

Also the conical surface

$$\begin{aligned}&=\pi\cdot \mathrm{BE}\,(\mathrm{BF}+\mathrm{EG})\ \text{(art. 67)}\\&=2\pi\cdot\mathrm{BF}\cdot\mathrm{BE},\ \text{ultimately},\\&=2\pi r\sin\theta\cdot\mathrm{FG}\operatorname{cosec}\theta\\&=2\pi r\cdot\mathrm{FG}.\end{aligned}$$

Now, as this value is independent of θ, and is ultimately the surface of the elementary zone generated by BH; it is evident that the surface of any segment or zone is equal to $2\pi r$ multiplied by the sum of the heights of the elementary zones of which it is composed. Hence if AG $=h$, the surface of the segment generated by ABH $=2\pi rh$: or if FG $=h$, the surface of the zone generated by BH $=2\pi rh$.

Also, the surface of the sphere is obviously

$$=2\pi r\times 2r=4\pi r^2.$$

72. (i.) *Hence the surface of a sphere is equal to four times the area of its great circle, or of a section by a plane passing through its centre.*

Example.—To find the surface of a sphere whose diameter is 7.

The surface of the circle whose diameter is 7 has been found (*Ex.* (ii.), art. 65) to be 38·4845.

Therefore the surface of the sphere $=4\times 38{\cdot}4845=153{\cdot}938$.

(ii.) *The convex surface of a segment, or zone of a sphere, is equal to the circumference of a great circle multiplied by the height of the segment or zone.*

Example.—Find the convex surface of a segment or of a zone whose height is 3, the diameter of the sphere being 5. The circumference of the circle whose diameter is 5 has been found (*Ex.* (i.), art. 45) to be 15·70796.

Therefore the surface of the segment or of the zone

$$=3\times 15{\cdot}70796=47{\cdot}12388.$$

73. *To find the Surface of a Lune, a Spherical Triangle, and a Spherical Polygon.*—It will be shown in spherical trigonometry—

(i.) That the area of a lune included between two great circles of a sphere whose inclination is θ,

$=2\theta r^2$; where r is the radius of the sphere;

(ii.) That the area of a spherical triangle whose angles are A, B, and C, $=r^2(\mathrm{A}+\mathrm{B}+\mathrm{C}-\pi)$; and

(iii.) That the area of a spherical polygon of n sides, the sum of whose angles is P, is

$$r^2\,\{\mathrm{P}-(n-2)\pi\}.$$

74. *To find the Volume of a Sphere.*—If we retain the figure and notation of art. 70, the volume of the segment generated by the revolution of the figure ABF,

$$=\pi\int_0^x y^2dx=\pi\int_0^x(2rx-x^2)\,dx=\frac{\pi x^2}{3}\,(3r-x).$$

Also the volume of the whole sphere

$$=\pi\int_0^{2r} y^2\,dx=\frac{4}{3}\pi r^3.$$

75. Or, if we suppose a regular polyhedron of n faces described about the sphere, by indefinitely increasing n, the surface and volume of the polyhedron will be ultimately equal respectively to the surface and volume of the sphere.

Now, if a^2 be put for one of the faces of the polyhedron, its volume is equal to n pyramids, whose bases are each a^2, and their common height the radius of the sphere.

Therefore the volume of the polyhedron

$$\begin{aligned}&=n\times\tfrac{1}{3}a^2r=\tfrac{1}{3}r\times na^2,\\&=\tfrac{1}{3}r\times\ \text{surface of polyhedron},\\&=\tfrac{1}{3}r\times\ \text{surface of sphere, ultimately},\\&=\tfrac{1}{3}r\times 4\pi r^2.\end{aligned}$$

Whence the volume of the sphere $=\frac{4}{3}\pi r^3$.

From this it follows that if d be the diameter of the sphere,

$$\text{the volume}=\tfrac{1}{6}\pi d^3.$$

$\therefore$ Since $\frac{4}{3}\pi=4{\cdot}1887902048$, and $\frac{1}{6}\pi={\cdot}5235987756$; *to find the volume of a sphere, multiply the cube of the radius by* 4·1887902, *or the cube of the diameter by* ·5235988.

Example.—Find the volume of a sphere whose radius is 12.

$$\begin{aligned}\text{The volume}=(12)^3\times\tfrac{4}{3}\pi&=1728\times 4{\cdot}1887902\\&=7238{\cdot}2295.\end{aligned}$$

76. It obviously follows from arts. 70 and 74 that in a sphere

$$\text{radius}=\frac{1}{2\sqrt{\pi}}\cdot\sqrt{(\text{surface})}=\sqrt[3]{\frac{3}{4\pi}}\cdot\sqrt[3]{(\text{volume})};$$

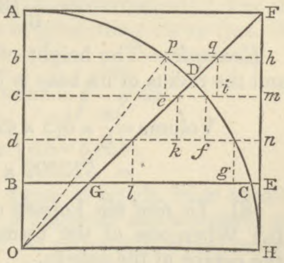
$$\text{diameter}=\frac{1}{\sqrt{\pi}}\cdot\sqrt{(\text{surface})}=\sqrt[3]{\frac{6}{\pi}}\cdot\sqrt[3]{(\text{volume})};$$

$$\text{surface}=\sqrt[3]{}\cdot\pi\sqrt[3]{(6\,\text{volume})^2};\ \text{volume}=\frac{1}{6\sqrt{\pi}}\cdot\sqrt{(\text{surface})^3}.$$

77. *To find the Volume of the Segment of a Sphere.*—The volume of a segment whose height is h

$$=\pi\int_0^h y^2dx=\pi\int_0^h(2rx-x^2)\,dx=\frac{\pi h^2}{3}\,(3r-h).$$

78. The same result may be obtained by supposing the parallelogram ABEF, the quadrilateral ABGF, and the segment ABCD, to revolve about AB so as to generate a cylinder, a frustum of a cone, and a segment of a sphere. If AB be divided into equal parts, Ab, bc, &c., each $=c$, and the rectangles be, bi, ch, cf, &c., be constructed, these rectangles will generate cylinders; and by indefinitely increasing the number of parts into which AB is divided, the sum of the cylinders generated by be, cf, &c., will ultimately be equal to the segment of the sphere generated by ABCD, and the sum of the cylinders generated by Ah, bi, &c., will ultimately be equal to the frustum of the cone generated by ABGF; while the cylinders generated by Ah, bm, &c., constitute the cylinder generated by ABEF.



$$\text{Now } bh^2=\mathrm{O}p^2=bp^2+\mathrm{O}b^2=bp^2+bq^2;$$

$$\therefore\ \pi c\cdot bh^2=\pi c\cdot bp^2+\pi c\cdot bq^2:$$

or the cylinder generated by bm is equal to the sum of those generated by be and bi; and because this is true of every corresponding set of cylinders, we have,

Sum of cylinders generated by Ah, bm, &c. $=$ sum of cylinders generated by be, cf, &c. $+$ sum of cylinders generated by Ah, bi, &c.

Therefore since these sums are ultimately equal respectively to the cylinder generated by ABEF, the sphere generated by ABCD, and the conic frustum generated by ABGF, we have

Cylinder $=$ segment of sphere $+$ frustum of cone.

Mensuration.

Now, if AF $=r$ and AB $=h$, we have

$$Bg=r-h\,;$$

therefore (art. 65) the frustum of the cone

$$=\frac{\pi h}{3}(3r^2-3rh+h^2).$$

Also, the cylinder (art. 68) $=\pi r^2h$; therefore the segment of the sphere

$$=\pi r^2h-\frac{\pi h}{3}(3r^2-3rh+h^2)$$

$$=\frac{\pi h^2}{3}(3r-h).$$

If we put $h=2r$, we obtain the volume of the whole sphere $=\frac{4}{3}\pi r^3$, as in art. 74.

Example.—Find the volume of the segment of a sphere; the radius being 12, and the height of the segment 6.

$$\text{The volume}=\frac{\pi}{3}\times 36\,(36-6)=3{\cdot}14159\times 360$$

$$=1130{\cdot}9733552.$$

79. It is evident that we may prove, in like manner, that the cylinder generated by AOHF is equal to the sum of the hemisphere and cone generated by ADHO and AOF. Whence it easily follows (arts. 63, 68), that if we have a cone and sphere inscribed in a cylinder,

the cylinder = sphere + cone = sphere + $\frac{1}{3}$ cylinder;

$\therefore$ the sphere = $\frac{2}{3}$ cylinder, and

cone : sphere : cylinder : : 1 : 2 : 3;

a relation also obviously true from their ascertained volumes, which are respectively $\frac{2}{3}\pi r^3$, $\frac{4}{3}\pi r^3$, and $2\pi r^3$.

80. Since, from the equation to the circle, $y^2=2rx-x^2$; putting a for the radius BC of the base of the segment generated by ABCD, we have

$$a^2=2rh-h^2\,;\quad \therefore\ r=\frac{a^2+h^2}{2h}.$$

Whence, substituting, we obtain the segment of a sphere, whose height is h, and the radius of its base a,

$$=\frac{\pi h}{6}(3a^2+h^2).$$

Example.—The height of a segment of a sphere is 5, and the radius of its base is 7.

$$\text{Volume}=\frac{\pi}{6}\times 5(3\times 49+25)$$

$$=\cdot 523599\times 860=450{\cdot}29.$$

81. *To find the Volume of the Frustum of a Sphere*—(i.) When one of the terminating planes passes through the centre of the sphere.

Let BO $=l$, then AB or $h=r-l$; and the frustum generated by the revolution of BCHO = hemisphere generated by AOH − spherical segment generated by ABCD,

$$=\frac{2}{3}\pi r^3-\frac{\pi}{3}(r-l)^2\,(2r+l)=\frac{\pi l}{3}(3r^2-l^2).$$

Example.—Find the volume of the frustum of a sphere; the radius of the sphere being 12, the height of the frustum 6, and one of its terminating planes passing through the centre.

$$\text{The volume}=\frac{\pi}{3}\times 6\,(3\times 144-36)$$

$$=3{\cdot}14159\times 792$$

$$=2488{\cdot}1413816.$$

(ii.) When neither of the terminating planes passes through the centre.

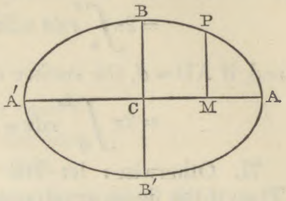
If h be the height of the frustum, and a_1, a_2 the radii of its ends,

$$\text{the volume}=\frac{\pi h}{6}\{3\,(a_1{}^2+a_2{}^2)+h^2\}.$$

Mensuration.

SECTION IV.—THE ELLIPSE.

82. *To find the Length of an Arc of an Ellipse.*—If AC $=a$, BC $=b$, CM $=x$, and MP $=y$, the equation to the ellipse is



$$a^2y^2+b^2x^2=a^2b^2\,;$$

$$\text{whence }\frac{dy}{dx}=-\frac{b^2x}{a^2y}.$$

The length of an arc BP

$$=\int_0^x\left(1+\frac{dy^2}{dx^2}\right)^{\frac{1}{2}}dx=\int_0^x\left(\frac{a^2-e^2x^2}{a^2-x^2}\right)^{\frac{1}{2}}dx,$$

$$\text{where } e^2=\frac{a^2-b^2}{a^2}.$$

Putting $x=az$,

$$\text{the arc BP}=a\int\frac{(1-e^2z^2)^{\frac{1}{2}}}{(1-\ z^2\,)^{\frac{1}{2}}}\,dz$$

$$=a\int\frac{dz}{(1-z^2)^{\frac{1}{2}}}\left\{1-\frac{1}{2}e^2z^2-\frac{1\cdot 1}{2\cdot 4}e^4z^4-\frac{1\cdot 1\cdot 3}{2\cdot 4\cdot 6}e^6z^6+\&c.\right\}$$

To obtain the length of a quadrant of the ellipse, we must integrate from $x=0$ to $x=a$, or from $z=0$ to $z=1$; when we obtain (see FLUXIONS)

$$\text{the quadrant APB}=\frac{\pi a}{2}\left\{1-\frac{e^2}{2^2}-\frac{1\cdot 3e^4}{2^2\cdot 4^2}-\frac{1\cdot 3^2\cdot 5e^6}{2^2\cdot 4^2\cdot 6^2}-\&c.\right\}:$$

a rapidly converging series when e is small.

83. We shall obtain more and more accurate values of the circumference of the ellipse according to the number of terms of the above series we employ. The following is the first approximation:—

$$\text{Since }(1-\tfrac{1}{2}e^2)^{\frac{1}{2}}=1-\frac{e^2}{2^2}+\&c.,$$

we have the elliptic quadrant $=\frac{\pi a}{2}(1-\frac{1}{2}e^2)^{\frac{1}{2}}$ nearly

$$=\frac{\pi}{2}\,a\left(1-\frac{a^2-b^2}{2a^2}\right)^{\frac{1}{2}}=\frac{\pi}{2}\left(\frac{a^2+b^2}{2}\right)^{\frac{1}{2}}:$$

and the circumference of the ellipse

$$=\pi\left\{\frac{(2a)^2+(2b)^2}{2}\right\}^{\frac{1}{2}}\text{ nearly.}$$

Hence the circumference of an ellipse is obtained approximately by multiplying the square root of half the sum of the squares of its axes by 3·14159.

Example.—Find the circumference of an ellipse whose axes are 3 and 4.

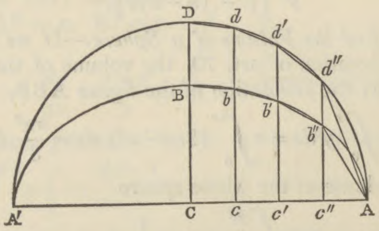
$$\text{The circumference}=3{\cdot}1416\left(\frac{9+16}{2}\right)^{\frac{1}{2}}$$

$$=\frac{3{\cdot}1416\times 5\sqrt{2}}{2}=11{\cdot}1\text{ nearly.}$$

84. *To find the Area of an Ellipse.*—The area of a quadrant ACB (fig. art. 82)

$$=\int_0^a ydx=\frac{b}{a}\int_0^a(a^2-x^2)^{\frac{1}{2}}dx=\frac{\pi ab}{4}.$$

85. Or if the ellipse ABA′ and the circle ADA be divided by lines cd, $c'd'$, &c., indefinitely near to each other, and parallel to CD, the polygons ACDd'', ACBb'', will be



ultimately equal to the circular and elliptic quadrants, in which they are inscribed; and if AC = a, BC = b,

$bc : cd :: b'c' :: c'd' :: b : a$. (ANAL. GEOM., art. 92, p. 553.)

Therefore the trapezoid $bcc'b'$ is to $dcc'd'$ in the same ratio (art. 14); and hence also the polygon ACBb'' is to the polygon ACDd'' in the same ratio of a to b.

Therefore, since the polygons are ultimately equal to the elliptic and circular quadrants, and the latter $= \frac{1}{4}\pi a^2$, we have

$$a : b :: \tfrac{1}{4}\pi a^2 : \text{elliptic quadrant ABC}.$$

$$\text{Whence the elliptic quadrant} = \tfrac{1}{4}\pi ab;$$
$$\text{and the ellipse} = \pi ab.$$

As this is the same as $\frac{1}{4}\pi \times 2a \times 2b$, *the area of an ellipse is equal to the product of the major and minor axes multiplied by* ·78539.

Example.—Find the area of an ellipse whose axes are 3 and 4.

$$\text{Area} = 3 \times 4 \times {\cdot}78539 = 80{\cdot}110613.$$

Spheroids.

86. *To find the Surface of a Prolate Spheroid.*—The prolate spheroid is generated by the revolution of an ellipse (fig. art. 82) about its major axis AA′, and the equation to the generating curve is therefore

$$a^2y^2 + b^2x^2 = a^2b^2.$$

$$\text{Whence } \frac{dy}{dx} = -\frac{b^2x}{a^2y}; \text{ and if } e^2 = \frac{a^2-b^2}{a^2},$$

$$y\left(1 + \frac{dy^2}{dx^2}\right)^{\frac{1}{2}} = \frac{b}{a}\left(a^2 - e^2x^2\right)^{\frac{1}{2}}.$$

Therefore, putting CM = h, the convex surface of the frustum of the spheroid generated by the figure BCMP

$$= 2\pi\int_0^h y\left(1+\frac{dy^2}{dx^2}\right)^{\frac{1}{2}} = \frac{2\pi b}{a}\int_0^h (a^2 - e^2x^2)^{\frac{1}{2}}$$

$$= \frac{\pi ab}{e}\left\{\sin^{-1}\frac{eh}{a} + \frac{eh}{a}\left(1 - \frac{e^2h^2}{a^2}\right)^{\frac{1}{2}}\right\}.$$

87. To obtain the surface of the whole spheroid, we must integrate from $x = -a$, to $x = a$, when we obtain

$$\text{surface of spheroid} = \frac{2\pi ab}{e}\{\sin^{-1}e + e(1-e^2)^{\frac{1}{2}}\}$$

$$= 2\pi a^2\{1 - e^2 + \frac{(1-e^2)^{\frac{1}{2}}}{e}\cdot\sin^{-1}e\}.$$

Example.—Find the surface of a prolate spheroid whose axes are 5 and 3.

$$\text{Here } a = \frac{5}{2},\ b = \frac{3}{2};$$

$$\therefore e = \left(\frac{25-9}{25}\right)^{\frac{1}{2}} = \frac{4}{5}, \text{ and } 1 - e^2 = \frac{9}{25}.$$

$$\text{Hence the surface} = 2\pi\left(\frac{5}{2}\right)^2\left\{\frac{9}{25} + \frac{3}{5}\cdot\frac{5}{4}\sin^{-1}\frac{4}{5}\right\}$$

$$= 12{\cdot}5\pi\{{\cdot}36 + {\cdot}75\sin^{-1}0{\cdot}8\}$$

$$\text{Now } \log 0{\cdot}8 + 10 = 9{\cdot}90309 = \text{L}\sin 53°\ 7'\ 49''$$
$$= \text{L}\sin 53°{\cdot}130 \text{ nearly};$$

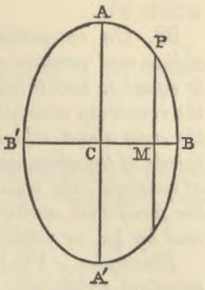
therefore (art. 51)

$$\sin^{-1}0{\cdot}8 = \frac{\pi}{180}\times 53{\cdot}130 = {\cdot}69547,$$

and the surface of the spheroid

$$= 3{\cdot}14159 \times 12{\cdot}5\,({\cdot}36 + {\cdot}69547) = 41{\cdot}448.$$

88. *To find the Surface of an Oblate Spheroid.*—The oblate spheroid is generated by the revolution of an ellipse AA′ about its minor axis BB. Hence if CM = x, and MP = y, the equation to the generating curve will be $a^2x^2 + b^2y^2 = a^2b^2$;



$$\therefore \frac{dy}{dx} = -\frac{a^2x}{b^2y}, \text{ and } y\left(1+\frac{dy^2}{dx^2}\right)^{\frac{1}{2}}$$

$$= \frac{a^2e}{b^2}(c^2 + x^2)^{\frac{1}{2}};$$

$$\text{where } e^2 = \frac{a^2-b^2}{a^2}, \text{ and } c = \frac{b^2}{ae} = \frac{a}{e}(1-e^2).$$

If CM = h, the convex surface generated by the revolution of the figure ACMP

$$= 2\pi\int_0^h y\left(1+\frac{dy^2}{dx^2}\right)^{\frac{1}{2}} = \frac{2\pi a^2e}{b}\int_0^h (c^2+x^2)^{\frac{1}{2}}\,dx$$

$$= \frac{\pi a^2}{e}\left\{h(c^2+h^2)^{\frac{1}{2}} + c^2\log\frac{h + (c^2+h^2)^{\frac{1}{2}}}{c}\right\}.$$

89. By integrating from $x = -b$ to $x = b$, we obtain the surface of the spheroid

$$= 2\pi a^2\left\{1 + \frac{1-e^2}{2e}\log\left(\frac{1+e}{1-e}\right)\right\}.$$

Example.—Find the surface of an oblate spheroid whose axes are 5 and 3.

$$\text{Here } a = \frac{5}{2},\ b = \frac{3}{2};\ \therefore e = \frac{4}{5}.$$

$$\text{Surface} = 2\pi\left(\frac{5}{2}\right)^2\left\{1 + \frac{5}{8}\cdot\frac{9}{25}\log\frac{1+\frac{4}{5}}{1-\frac{4}{5}}\right\}$$

$$= 12{\cdot}5\pi\left(1 + \frac{9}{40}\log 9\right).$$

$$\text{But } \frac{9}{40}\log_e 9 = \frac{9}{40}\times 2{\cdot}1972246 = {\cdot}4943755;^*$$

$$\therefore \text{surface} = 12{\cdot}5 \times 3{\cdot}14159 \times 1{\cdot}4943755 = 58{\cdot}685.$$

90. *To find the Volume of a Spheroid.*—(i.) For the *prolate spheroid* the equation to generating curve (art. 86) is $a^2y^2 + b^2x^2 = a^2b^2$.

$$\text{Whence the volume } \pi\int_{-a}^{+a} y^2dx$$

$$= \frac{\pi b^2}{a^2}\int_{-a}^{+a}(a^2 - x^2)\,dx = \tfrac{4}{3}\pi ab^2.$$

91. Or if we conceive the figure of article 84 to revolve about AA′, so as to generate a spheroid and a sphere, we may conceive these solids to be ultimately equal to two series of elementary cylinders described by the rectangles, whose bases are BC, bc, &c., and CD, cd, &c., and whose common altitude is Cc = cc' = &c.

$$\text{Then, because BC}^2 : \text{CD}^2 :: (bc)^2 : (cd)^2 :: b^2 : a^2;$$

$$\therefore \pi(bc)^2\cdot cc' : \pi(cd)^2\cdot cc' :: b^2 : a^2.$$

Whence the corresponding pairs of elementary cylinders which constitute the sphere and spheroid are in the constant ratio of a^2 to b^2; and since the sphere $= \frac{4}{3}\pi a^3$;

$$\therefore a^2 : b^2 :: \tfrac{4}{3}\pi a^3 : \text{spheroid}.$$

Hence the spheroid $= \frac{4}{3}\pi ab^2$.

92. (ii.) For the *oblate spheroid* the equation to the generating curve is $a^2x^2 + b^2y^2 = a^2b^2$ (art. 88).

$$\text{Whence the volume} = \pi\int_{-b}^{+b} y^2dx$$

$$= \frac{\pi a^2}{b}\int_{-b}^{+b}(a^2 - x^2)\,dx = \tfrac{4}{3}\pi a^2b.$$

---

* To obtain the logarithm of any number to the base e, multiply its common logarithm to the base 10 by 2·3025850929. Thus $\log_e 9 = {\cdot}9542425 \times 2{\cdot}3025850929 = 2{\cdot}1972246$.

The same result may also be obtained by the method of article 91.

93. *On comparing the expressions for the volumes of oblate and prolate spheroids, it appears that either volume is equal to two-thirds the area of the circle generated by the revolving axis of the ellipse, multiplied by the length of the axis about which it revolves: or the spheroid is two-thirds of the circumscribing cylinder. Also, for both species of spheroid, the volume is equal to the continued product of the fixed axis, multiplied by the square of the revolving axis, and by* $\frac{1}{6}\pi$, *or* ·52359878.

Examples.—Find the volumes of an oblate and prolate spheroid whose axes are 20 and 12.

The volume of the oblate spheroid

$$=\tfrac{4}{3}\pi \times 100 \times 6 = 800\pi = 2513{\cdot}274.$$

The volume of the prolate spheroid

$$=\tfrac{4}{3}\pi \times 36 \times 10 = 480\pi = 1057{\cdot}962.$$

94. *To find the Volume of a Segment of a Spheroid.*

(i.) *The prolate spheroid.*—The segment is generated by the revolution of AMP about AM (fig. art. 82).

If A be the origin, and AA′ the axis of x, the equation to the ellipse is

$$y^2 = \frac{b^2}{a^2}(2ax - x^2);$$

and if AM$=h$, the volume of the segment

$$=\pi\int_0^h y^2 dx,$$

$$=\frac{\pi b^2}{a^2}\int_0^h (2ax - x^2)\,dx = \frac{\pi}{3}\cdot\frac{b^2h^2}{a^2}(3a - h).$$

Example.—Find the volume of the segment of a prolate spheroid, where the axes of the generating ellipse are 20 and 12, and the height of the segment 8.

Here $a=10$, $b=6$, $h=8$.

The volume

$$=\frac{\pi}{3}\cdot\frac{36\times 64}{100}(30-8) = 3{\cdot}14159 \times \frac{12\times 64\times 22}{100} = 530{\cdot}8034.$$

95. (ii.) *The oblate spheroid.*—The segment is generated by the revolution of BMP (fig. art. 88) about BM; where, if B be the origin and BB′ the axis of x, the equation to the ellipse is

$$y^2 = \frac{a^2}{b^2}(2bx - x^2);$$

and if BM$=h$, the volume of the segment

$$=\frac{\pi a^2}{b^2}\int_0^h (2bx - x^2)\,dx = \frac{\pi}{3}\cdot\frac{a^2h^2}{b^2}(3b - h).$$

Example.—Find the volume of a segment of an oblate spheroid, the axes being 20 and 12, and the height of the segment 2.

$$a=10,\ b=6,\ h=2;$$

and the volume$=\frac{\pi}{3}\cdot\frac{100\times 4}{36}(18-2) = 186{\cdot}1658.$

96. *To find the Volume of the Frustum of a Spheroid when one of the Terminating Planes passes through the Centre.*

(i.) *The prolate spheroid.*—The frustum is generated by the revolution of the figure BCMP (fig. art. 82) about CM; and if CM$=h$, the volume of the frustum

$$=\frac{\pi b^2}{a^2}\int_0^h (a^2 - x^2)\,dx = \frac{\pi}{3}\cdot\frac{b^2h}{a^2}(3a^2 - h^2).$$

If b, b' be the radii BC, PM of the terminating planes of the frustum, since from the equation to the ellipse

$$b^2h^2 + a^2b'^2 = a^2b^2;\ \therefore\ h^2 = \frac{a^2(b^2 - b'^2)}{b^2}.$$

Whence, by substitution, the volume of the frustum

$$=\frac{\pi}{3}h(2b^2 + b'^2).$$

Example.—Find the volume of the frustum of a prolate spheroid whose axes are 20 and 12, the height of the frustum being 2, and one of its ends passing through the centre of the spheroid.

$$a=10,\ b=6,\ h=2.$$

The volume$=\frac{\pi}{3}\cdot\frac{36\times 2}{100}(300-4) = 223{\cdot}1787.$

97. (ii.) *The oblate spheroid.*—Adopting the figure and notation of article 88, the frustum is generated by the revolution of ACMP about CM. The equation is

$$a^2x^2 + b^2y^2 = a^2b^2;$$

and if CM$=h$, the volume

$$=\frac{\pi a^2}{b^2}\int_0^h (b^2 - x^2)\,dx = \frac{\pi}{3}\cdot\frac{a^2h}{b^2}(3b^2 - h^2).$$

Also, if a, a' be the radii of the terminating planes, since from the equation to the ellipse

$$a^2h^2 + a'^2b^2 = a^2b^2,$$

if we substitute for h^2 we obtain the volume

$$=\frac{\pi}{3}h(2a^2 + a'^2).$$

Example.—Find the volume of the frustum of an oblate spheroid whose axes are 20 and 12, the height of the frustum being 4, and one of its ends passing through the centre of the spheroid.

$$a=10,\ b=6,\ c=4.$$

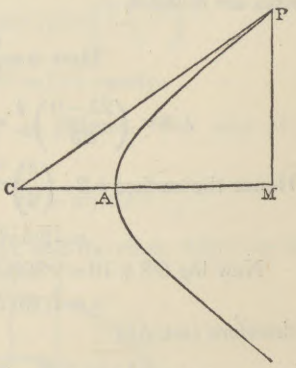
The volume$=\frac{\pi}{3}\cdot\frac{100\times 4}{36}(108-16) = 1070{\cdot}469.$

It appears also from the last two articles that the volume of a frustum, of either a prolate or oblate spheroid, one of whose ends passes through the centre of the generating ellipse, is obtained by adding the area of the smaller end to twice that of the greater, and multiplying the sum by one-third of the altitude of the frustum.

SECTION. V.—THE HYPERBOLA.

98. *To find the Area of an Hyperbola.*

(i.) The area of the segment AMP.



Let C be the centre, and CM the axis of x. The equation is

$$a^2y^2 - b^2x^2 = -a^2b^2;$$

and if CM$=h$, PM$=k$, the area AMP

$$=\int_a^h y\,dx = \frac{b}{a}\int_a^h (x^2 - a^2)^{\frac{1}{2}}$$

$$=\frac{b}{a}\left\{\frac{h}{2}(h^2 - a^2)^{\frac{1}{2}} - \frac{a^2}{2}\log\frac{h + (h^2 - a^2)^{\frac{1}{2}}}{a}\right\}$$

$$=\tfrac{1}{2}hk - \frac{ab}{2}\log\left(\frac{h}{a} + \frac{k}{b}\right);$$

where $b = \frac{ak}{(h^2 - a^2)^{\frac{1}{2}}}\cdot$

Example.—Find the area of a hyperbolic segment whose base is 48 and altitude 20; the transverse axis of the curve being 60.

$$a=30,\ k=24,\ \text{and}\ x=30+20=50;$$

$$\text{also } b=\frac{30\times 24}{(2500-900)^{\frac{1}{2}}}=\frac{720}{40}=18.$$

The area AMP

$$=\tfrac{1}{2}\times 50\times 24-\frac{30\times 18}{2}\log_e\left(\frac{50}{30}+\frac{24}{18}\right)$$

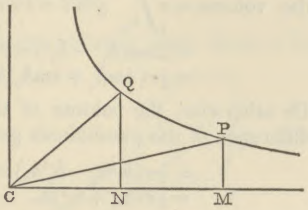
$$=600-270\log_e 3=600-270\times 1{\cdot}0986123\ \text{(note, art. 89)}$$
$$=303{\cdot}3756.$$

Hence the whole segment, which is double AMP,

$$=606{\cdot}7513.$$

99. (ii.) The area of the sector ACP.

$$\text{The area ACP}=\text{CMP}-\text{AMP}=\tfrac{1}{2}hk-\text{AMP}$$
$$=\frac{ab}{2}\log\left(\frac{h}{a}+\frac{k}{b}\right).$$



100. *To find the Area bounded by a Rectangular Hyperbola and its Asymptotes.*—The equation to the hyperbola referred to its asymptotes is

$$xy=\frac{a^2}{2}.$$

Let $\text{CM}=x_1$, $\text{CN}=x_2$, $\text{PM}=y_1$, $\text{QN}=y_2$.

$$\text{The area PMNQ}=\int_{x_2}^{x_1} y\,dx$$

$$=\frac{a}{2}\int_{x_2}^{x_1}\frac{dx}{x}=\frac{a^2}{2}\log\frac{x_1}{x_2}=\frac{a^2}{2}\log\frac{y_2}{y_1}.$$

From the equation:

$$\frac{x_1y_1}{2}=\frac{a^2}{4}=\frac{x_2y_2}{2},\ \text{or triangle CMP}=\text{triangle CNQ}.$$

Whence sector PCQ = area PMNQ.

101. If the ordinates $\text{PM}=k_1$, $\text{QN}=k_2$, and $\text{MN}=h$, be given, putting x_1, x_2 for CM, CN, as before,

$$x_1k_1=\frac{a^2}{2}=x_2k_2,\ \text{and}\ x_1-x_2=h.$$

$$\text{Whence}\ \frac{a^2}{2}=\frac{hk_1k_2}{k_2-k_1},$$

$$\text{and area PMNQ}=\frac{hk_1k_2}{k_2-k_1}\log\frac{k_2}{k_1}.$$

Example.—Given the ordinates PM = 20, QN = 45, and MN = 50, to find the area.

$$\text{Here}\ k_1=20,\ k_2=45,\ \text{and}\ h=50.$$

$$\text{The area}\ =\frac{50\times 20\times 45}{45-20}\log\frac{45}{20}$$

$$=1800\log\frac{9}{4}=1459{\cdot}67.$$

102. *To find the Volume of an Hyperboloid.*—The solid is generated by the revolution of the hyperbolic segment AMP about AM (fig. art. 98).

If, therefore, we put $\text{AM}=h$,

$$\text{the volume}=\pi\int_a^{a+h}y^2=\frac{\pi b^2}{a^2}\int_a^{a+h}(x^2-a^2)\,dx$$

$$=\frac{\pi b^2h^2}{3a^2}(3a+h).$$

103. If $\text{PM}=k$, from the equation to the hyperbola (art. 98),

$$ak^2-b^2(a+h)^2=-a^2b^2.$$

$$\text{Whence}\ \frac{b^2}{a^2}=\frac{k^2}{2ah+h^2}.$$

Therefore substituting, we obtain the volume of the hyperboloid,

$$=\frac{\pi hk^2}{3}\cdot\frac{3a+h}{2a+h}.$$

Example.—Find the volume of an hyperboloid, the radius of whose base is 24, its height 20, and the transverse axis of the generating curve 60.

$$\text{Here}\ a=30,\ k=24,\ h=20.$$

$$\text{The volume}\ =\frac{\pi\times 20\times(24)^2}{3}\cdot\frac{90+20}{60+20}$$
$$=5280\pi=16587{\cdot}6092.$$

104. The expression for the volume may be put into the form

$$\frac{\pi hk^2}{2}\cdot\frac{2a+\frac{2}{3}h}{2a+h},$$

whence the following rule:—*As the sum of the transverse axis of the generating hyperbola, and the height of the solid, is to the sum of the transverse axis and $\frac{2}{3}$ of the height, so is half the cylinder of the same base and altitude to the volume of the hyperboloid.*

105. *To find the Volume of the Solid generated by the Revolution of a Rectangular Hyperbola about its Asymptote.*

The solid is generated by the revolution of PMNQ (fig. art. 100) about MN.

If $\text{CM}=x_1$, $\text{CN}=x_2$, and $\text{MN}=h$,

$$\text{the volume}=\pi\int_{x_2}^{x_1}y^2dx=\frac{\pi a^4}{4}\int_{x_2}^{x_1}\frac{dx}{x^2}$$

$$=\frac{\pi a^4}{4}\left(\frac{1}{x_2}-\frac{1}{x_1}\right)=\frac{\pi a^4h}{x_1x_2}.$$

Now if r_1, r_2 be the radii PM, QN of the ends of the solid,

$$r_1x_1=r_2x_2=\frac{a^2}{2};$$

$$\text{therefore}\ x_1x_2=\frac{a^4}{4r_1r_2}.$$

$$\text{Whence the volume}=\pi r_1r_2h;$$

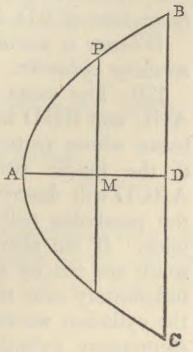
or the volume is equal to the continued product of the radii of its ends, its height, and 3·14159.

Example.—Find the volume of the hyperbolic solid generated by PMNQ, where PM = 20, QN = 45, and MN = 50.

$$\text{The volume}=20\times 45\times 50\times\pi$$
$$=141371{\cdot}669.$$

SECTION VI.—THE PARABOLA.

106. *To find the Length of an Arc of a Parabola.*—The equation to the parabola being $y^2=4mx$, the length of the arc AB, where $\text{AD}=h$,



$$=\int_0^h\left(1+\frac{dy^2}{dx^2}\right)^{\frac{1}{2}}dx$$

$$=\int_0^h\left(1+\frac{m}{x}\right)^{\frac{1}{2}}dx$$

$$=(mh+h^2)^{\frac{1}{2}}$$

$$+\frac{m}{2}\log\left\{\frac{m+2[h+(mh+h^2)^{\frac{1}{2}}]}{m}\right\}.$$

$$\text{If BD}=b,\ b^2=4mh;\ \therefore m=\frac{b^2}{4h}.$$

Whence the arc BAC

$$=(b^2+4h^2)^{\frac{1}{2}}+\frac{b^2}{4h}\log\left\{\frac{b^2+8[h^2+(b^2+4h^2)^{\frac{1}{2}}]}{b^2}\right\}.$$

Example.—If AD = 4, and BC = 12, then $b = 6$, and $h = 4$.

$$\text{The arc BAC} = 10 + \frac{9}{4}\log_e\frac{61}{9}$$

$$= 10 + \frac{9}{4} \times 1{\cdot}9236493 = 14{\cdot}3282.$$

107. *To find the Area of a Parabola.*—In the figure of last article the area ABD

$$= \int_0^x y\,dx = 2m^{\frac{1}{2}}\int_0^x x^{\frac{1}{2}}dx$$

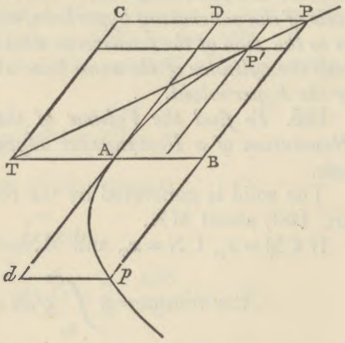
$$= \tfrac{4}{3}m^{\frac{1}{2}}x^{\frac{3}{2}} = \tfrac{2}{3}xy.$$

Or if AD $= h$, and BD $= b$,

$$\text{the area ABD} = \tfrac{2}{3}bh.$$

Whence the area ABC $= \tfrac{2}{3}$AD·BC.

108. Or if PT be a tangent to the parabola AP, AB a diameter, and P′ a point in the curve indefinitely near to P; then P′ will ultimately be on the line PT, and the parallelograms P′C, P′B will be equal. But because AB = AT (CONIC SECTIONS, vol. vii., p. 255, prop. ix.), PD = ½PC, therefore the parallelogram P′B is double the parallelogram P′D; and, if we take a succession of points, such as PP′, indefinitely near to each other, the areas APB, APD may be conceived to be made up of parallelograms, every parallelogram in the area APB being double the corresponding parallelogram in APD. Hence the area APB is double APD, or APB is ⅔ the parallelogram ABPD. From this it follows that PAp = ⅔PDdp; *or the area of a parabola is two-thirds of the circumscribed parallelogram.*



Example.—The base of a parabolic segment is 10 and its height 4.

$$\text{The area} = \tfrac{2}{3} \times 10 \times 4 = 26\tfrac{2}{3}.$$

109. *To find the Volume of a Paraboloid.*—The parabola ABD (fig. art. 106) revolving about AD $= h$, generates the paraboloid whose volume

$$= \pi\int_0^h y^2dx = 4\pi m\int_0^h x\,dx = 2\pi mh^2.$$

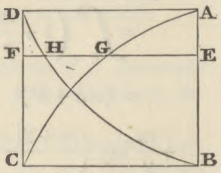
Or if BD $= b$, since $4mh = b^2$,

$$\text{the volume} = \tfrac{1}{2}\pi b^2h.$$

The cylinder whose base is the circle described by the revolution of BD, and whose altitude is AD, $= \pi b^2h$.

Whence a paraboloid is equal to one-half its circumscribing cylinder.

110. The same result may also be obtained thus:—If AGC and BHD be two equal parabolas, whose vertices are A, B, and if the figure revolve round AB, ABCD will describe a cylinder, and the parabolas will describe paraboloids. If we also suppose that the solids are cut by a number of planes indefinitely near to each other and parallel to the base of the cylinder, we may conceive the solids to be made up of elementary cylinders constituted between the contiguous planes.



Now, if $y^2 = px$ be the equation to the parabolas,

$$\text{EG}^2 = p\cdot\text{AE, and EH}^2 = p\cdot\text{EB};$$

$$\therefore \text{EG}^2 + \text{EH}^2 = p\cdot(\text{AE} + \text{BE}) = p\cdot\text{AB} = \text{BC}^2 = \text{EF}^2.$$

Also if we put h for the height of the cylinders whose bases are in the plane described by EF, their volumes will be $\pi h\cdot\text{EG}^2$, $\pi h\cdot\text{EH}^2$, $\pi h\cdot\text{EF}^2$; and since $\pi h\cdot\text{EG}^2 + \pi h\cdot\text{EH}^2 = \pi h\cdot\text{EF}^2$, and a similar relation exists for every corresponding set of cylinders, it follows that the elementary cylinders which constitute the paraboloids are ultimately equal to those which constitute the whole cylinder.

Hence the two paraboloids are together equal to the whole cylinder; and since the paraboloids are equal to each other, each is equal to half the cylinder.

Example.—The diameter of the base of a paraboloid is 10, and its height 4.

$$\text{Here } h = 4, \text{ and } b = 5.$$

$$\text{The volume} = \tfrac{1}{2}\pi \times 25 \times 4 = 157{\cdot}0795.$$

111. *To find the Volume of the Frustum of a Paraboloid.*—The frustum is generated by the revolution of BDMP (fig. art. 106) about DM, where if AD $= h_1$, AM $= h_2$, DM $= h$, BD $= b_1$, MP $= b_2$,

$$\text{the volume} = \pi\int_{h_2}^{h_1} y^2dx = 4\pi m\int_{h_2}^{h_1} x\,dx$$

$$= 2\pi m(h_1^2 - h_2^2) = 2\pi m(h_1 + h_2)\,h$$

$$= \tfrac{1}{2}\pi(4mh_1 + 4mh_2)h = \tfrac{1}{2}\pi(b_1^2 + b_2^2)h.$$

Or otherwise, the volume of the frustum is equal to the difference of the paraboloids generated by ABD, AMP

$$= \tfrac{1}{2}\pi(b_1^2h_1 - b_2^2h_2) = 2m\pi(h_1^2 - h_2^2)$$

$$= \tfrac{1}{2}\pi(b^{\,2} + b_2^2)h.$$

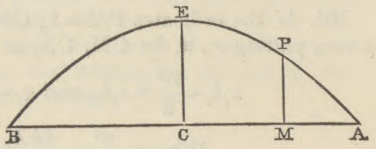
Now since πb_1^2, πb_2^2 are the areas of the circles generated by the revolution of BD and MP, it follows that *the volume of the frustum of a paraboloid is equal to half the sum of the areas of its ends multiplied by its height.*

Example.—The radii of the ends of the frustum of a paraboloid are 3 and 6, and its height is 3.

$$\text{The volume} = \frac{\pi}{2} \times (36 + 9) \times 3$$

$$= 212{\cdot}058.$$

112. *To find the Volume of a Parabolic Spindle.*—The parabolic spindle is generated by the revolution of the parabola AEB about AB, a line at right angles to CE, the axis of the curve.



If CM $= x$, and MP $= y$, the equation to the curve is

$$y = a - \frac{x^2}{p}, \text{ where EC} = a.$$

Wherefore, if AC $= b$, we have $b^2 = ap$, and the volume generated by the revolution of ACE

$$= \pi\int_0^b y^2dx = \pi\int_0^b \left(a^2 - \frac{2ax^2}{p} + \frac{x^4}{p^2}\right)dx$$

$$= \frac{8}{15}\pi a^2b.$$

Hence the volume generated by the revolution of AEB *is equal to* $\tfrac{8}{15}$ *of a circumscribed cylinder.*

Example.—The length of a parabolic spindle is 12, and its middle diameter is 8.

$$\text{Here } a = 4,\ 2b = 12.$$

$$\text{The volume} = \frac{8}{15}\pi \times 16 \times 12 = 321{\cdot}699.$$

113. *To find the Volume of the Frustum of a Parabolic Spindle.*—The frustum is generated by the revolution of CEPM about CM.

If PM $=a'$, and CM $=h$, from the equation to the parabola

$$a'=a-\frac{h^2}{p},$$

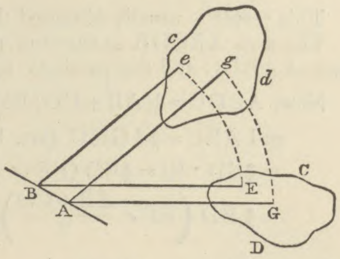
$$\text{and the volume }=\int_0^h\left(a^2-\frac{2ax^2}{p}+\frac{x^4}{p^2}\right)dx$$
$$=\frac{\pi h}{15}(8a^2+4aa'+3a'^2).$$

Example.—Find the volume of the frustum of a parabolic spindle, the radius of the end passing through the centre of the entire spindle being 16, the radius of the other end 12, and the length 20.

$$\text{The volume}=\frac{20\pi}{15}(8\times 256+4\times 16\times 12+3\times 144)$$
$$=13605\cdot 19.$$

SECTION VII.—ON THE DETERMINATION OF THE VOLUMES AND SURFACES OF SOLIDS OF REVOLUTION, GENERATED BY PLANE FIGURES WHOSE AREAS AND CENTRES OF GRAVITY ARE KNOWN.

114. Let a solid be generated by any plane figure CD, revolving round an axis AB, in the same plane, but which is supposed not to cut CD. The area CD, and the distance AG of the centre of gravity of CD from the axis AB, being known, it is required to find the volume and surface of the solid.



(i.) *To find the volume of the solid.* — Let the plane of the figure CD, in its initial position, be the plane of (x, y); let AB be the axis of x, and let θ be the angle GAg through which CD revolves. Then an elementary area $\delta x\delta y$ of the figure CD, in revolving through an angle $\delta\theta$, will generate an elementary solid whose volume is $y\delta\theta\delta x\delta y$. Therefore the whole solid

$$=\int_0^\theta\iint y\,d\theta\,dx\,dy=\theta\iint dx\,dy.$$

The limits of x and y will depend upon the nature of the revolving curve. But if $\bar{y}$ be the distance AG of the centre of gravity from AB, we shall have, from the nature of the centre of gravity,

$$\bar{y}=\frac{\iint y\,dx\,dy}{\iint y\,dx\,dy};$$

the limits of x and y being the same as before. Therefore the whole solid

$$=\theta\bar{y}\iint dx\,dy=\text{arc G}g\times\text{area CD}.$$

A more elementary proof may be obtained as follows:—If A, the area CD, be made up of the elements a_1, a_2, ... a_n, whose respective distances from AB are y_1, y_2 . . . . . y_n: then the solid generated by the element a_1 at E

$$=a_1\times\text{arc E}e=a_1\times\text{BE}\times\text{angle EB}e=a_1y_1\theta;$$

and the whole solid

$$=\theta(a_1y_1+a_2y_2+\;.\;.\;.\;.\;.\;+a_ny_n)=\theta\bar{y}\text{A},$$
$$=\text{arc G}g\times\text{area CD}.$$

Hence if any plane figure revolve about an axis which lies in the same plane with it, but does not cut it, the volume of the solid which is generated is equal to a prism whose base is the revolving figure, and whose height is the length of the path described by the centre of gravity of the area of the plane figure.

If the figure CD make a complete revolution round AB, $\theta=2\pi$;

$\therefore$ the solid = area CD × circle whose radius is AG.

115. (ii.) *To find the surface of the solid.*—The surface generated by an element δs of the perimeter of the figure CD, revolving through an angle $\delta\theta$, is $y\delta\theta\delta s$; therefore the whole surface

$$=\int_0^\theta\int y\,d\theta\,ds=\theta\int y\,ds.$$

The limits depend upon the nature of the figure CD; but if $\bar{y}=$ AG, the distance of the centre of gravity of the perimeter of CD, from AB,

$$\bar{y}=\frac{\int y\,ds}{\int ds}.$$

Therefore the surface of the solid generated by CD

$$=\theta\bar{y}\int ds=\text{arc G}g\times\text{perimeter of CD}.$$

The same result may be obtained, if in the second demonstration of the last proposition we substitute the elements of the perimeter of CD for those of the surface CD.

Hence if any plane figure revolve about an axis in the same plane with it, but which does not cut it, the surface of the solid which is generated is equal to a rectangle whose base is the perimeter of the revolving figure, and whose altitude is the length of the path described by the centre of gravity of the perimeter.

If the figure CD make a complete revolution, the surface of the solid

= perimeter of CD × circle whose radius is Ag.

116. *To find the Volume and Surface of a Circular Ring.*—Let a be the distance of the centre of the generating circle from the axis round which it revolves to generate the ring, and r the radius of the generating circle.

Then the path described by the centre of gravity, either of the area or perimeter of the generating circle $=2\pi a$.

Also area of circle $=\pi r^2$.
Perimeter of circle $=2\pi r$.
Hence volume of ring $=2\pi^2ar^2$.
Surface of ring $=4\pi^2ar$.

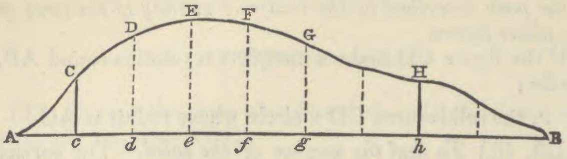
Example.—Find the volume and surface of a ring 4 inches thick, and whose internal diameter is 6 inches.

Here the radius of the generating circle is 2 inches, and the radius of the circle described by the centre of gravity is 5 inches.

Volume of ring $=2\pi^2\times 5\times 2^2$
$=40\times 9\cdot 8696044=394\cdot 784$ cubic inches.
Surface of ring $=4\pi^2\times 2\times 5$
$=40\pi^2=394\cdot 784$ square inches.

SECTION VIII.—ON THE APPROXIMATE DETERMINATION OF THE AREAS OF CURVES, AND THE VOLUMES OF SOLIDS, BY MEANS OF EQUIDISTANT ORDINATES, OR EQUIDISTANT SECTIONS.

117. Let AEB be any curve, and let the ordinates Cc, Dd, &c., be drawn perpendicular to AB, dividing it into equal parts. Having given the lengths of the ordinates and their common distance, it is required to determine, either accurately or approximately, the areas of the whole curve AEB, or of the portion CEH*hc*; and also the volumes of the solids generated by the revolution of these figures about the line AB.



118. *To find the Area of the Curve.*—(i.) As the ordinates C*c*, D*d*, &c., are supposed to be near to each other, if straight lines be drawn between AC, CD, &c., these lines will nearly coincide with the curve, and its area will be nearly equal to the sum of the two triangles AC*c*, BH*h*, and the trapezoids CD*dc*, DE*dc*, &c.

Hence, putting

$$\mathrm{C}c=a_1,\ \mathrm{D}d=a_2,\ \ldots\ \mathrm{H}h=a_n, \text{ and } \mathrm{A}c=cd=\&\text{c.}=h,$$

we may assume (arts. 10, 14) that the surface AEB is nearly equal to

$$\tfrac{1}{2}a_1h+\tfrac{1}{2}(a_1+a_2)h+\tfrac{1}{2}(a_2+a_3)h+\ \ldots\ +\tfrac{1}{2}a_nh;$$

$$\text{or area}=h(a_1+a_2+a_3+\ \ldots\ +a_n) \text{ nearly.}$$

Similarly it may be shown that the area of the figure CEH*hc*

$$=\tfrac{1}{2}h\{a_1+a_n+2(a_2+a_3+\ \ldots\ +a_{n-1})\} \text{ nearly.}$$

Therefore *the area of any figure contained by a straight line and a curve is equal to the sum of the equidistant ordinates multiplied by their common distance; or if the figure be contained by a straight line, two perpendiculars at its ends, and a curve, its area is equal to the two perpendiculars added to twice the sum of the intermediate ordinates, and multiplied by half their common distance.*

Example 1.—In a figure AEB, the ordinates are 5, 7, 9, 13, 8, 6, and 4, and their common distance 3.

$$\text{The area}=3\,(5+7+9+13+8+6+4)=156 \text{ nearly.}$$

Example 2.—In a figure such as CEH*hc*, where the ordinates taken in order are a_1, a_2, ... a_7; the common distance of the ordinates = 1, and their values are as follows:—

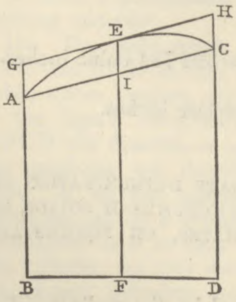
$$\begin{array}{r}
a_2=10\cdot9087121\\
a_3=11\cdot3137085\\
a_4=11\cdot6189500\\
a_5=11\cdot8321596\\
a_6=11\cdot9582607\\
\hline
\text{Sum}=57\cdot6317909\\
2\\
\hline
115\cdot2635818
\end{array}
\qquad
\begin{array}{r}
a_1=10\cdot3923048\\
a_7=12\\
\hline
22\cdot3923048\\
115\cdot2635818\\
\hline
2)\overline{137\cdot6558866}\\
\hline
\text{area}=68\cdot8279433
\end{array}$$

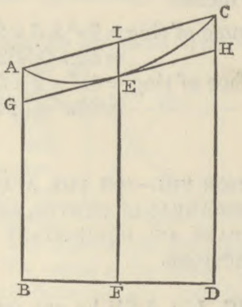
119. (ii.) A very close approximation to the areas of any curvilineal figures, such as AEB or C*ch*H (fig. art. 117), may generally be obtained by the following method:—

Let *ch* (art. 117) be divided into any *even* number of equal parts; and let ABDC (art. 119) represent a portion of the figure C*ch*H (art. 117), such as C*ce*E terminated by two *odd* ordinates C*c*, E*e*; then a curve, whose equation is

$$y=m+nx+px^2,$$

may be supposed to pass through the points A, E, C (art. 119): and since these points are near each other, the curve will coincide either accurately or very nearly with the curve AEC.





Let F be the origin, and put AB = a_1, EF = a_2, CD = a_3, and BF = FD = h.

$$\begin{array}{rl}
\text{Then when } x= & 0,\ y=a_2\\
x= & h,\ y=a_3\\
x= & -h,\ y=a_1:
\end{array}$$

and substituting in the equation, we obtain

$$\begin{array}{l}
a_2=m\\
a_1=a_2-nh+ph^2\\
a_3=a_2+nh+ph^2.
\end{array}$$

$$\text{Whence } n=\frac{a_3-a_1}{2h};\ p=\frac{a_3-2a_2+a_1}{2h^2}.$$

We have then the area AECDB

$$=\int_{-h}^{h}ydx=\int_{-h}^{h}(m+nx+px^2)\,dx$$

$$=2\left(mh+\frac{ph^3}{3}\right)=\tfrac{1}{3}h(a_1+4a_2+a_3).$$

This result is usually obtained thus:—

The area AECDB is the sum or difference of the trapezoid ABDC and the parabolic segment AEC.

Now, $\mathrm{ABDC}=\tfrac{1}{2}(\mathrm{AB}+\mathrm{CD})\,\mathrm{BD}=(a_1+a_3)\,h$ (art. 14);

and $\mathrm{AEC}=\tfrac{2}{3}\mathrm{AGHC}$ (art. 108).

$$=\tfrac{2}{3}\mathrm{BD}\cdot\mathrm{EI}=\tfrac{2}{3}\mathrm{BD}\,(\mathrm{EF}\backsim\mathrm{IF})$$

$$=\tfrac{2}{3}\,\mathrm{BD}\left(\mathrm{EF}\backsim\frac{\mathrm{AB}+\mathrm{CD}}{2}\right)=\tfrac{4}{3}h\left(a_2\backsim\frac{a_1+a_3}{2}\right)$$

Therefore the area AECDB

$$=h(a_1+a_3)\pm\tfrac{4}{3}h\left(a_2\backsim\frac{a_1+a_3}{2}\right)$$

$$=\tfrac{1}{3}h(a_1+4a_2+a_3).$$

120. If now we put (fig. art. 117) the ordinates C*c* = a_1, D*d* = a_2, E*e* = a_3, ... H*h* = a_n,

$$\text{we have } \mathrm{C}ce\mathrm{E}=\tfrac{1}{3}h(a_1+4a_2+a_3);$$

$$\mathrm{E}eg\mathrm{G}=\tfrac{1}{3}h(a_3+4a_4+a_5),\ \&\text{c.}$$

Therefore the figure C*ch*H

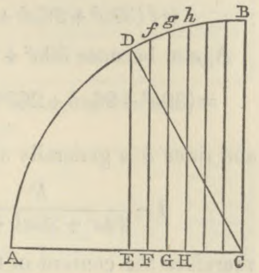
$$=\tfrac{1}{3}h\{a_1+a^n+2(a_3+a_5+\ldots+a_{n-2})+4(a_2+a_4+\ldots+a_{n-1})\}.$$

121. The area ABGD may be derived from C*ch*H by putting $a_1=a_n=0$. Substituting $a_1 \ldots a_r$ for the remaining ordinates $a_2 \ldots a_{n-1}$, we then obtain the figure ABGD

$$=\tfrac{2}{3}h\{a_2+a_4+\ldots+a_{r-1}+2(a_1+a_3+\ldots a_r)\}.$$

122. From the preceding demonstrations it follows, that the area of any curvilineal figure, such as C*ch*H (art. 117) whose base is divided into an *even number* of equal parts by equidistant ordinates, is obtained by the following rule:—*Add together the two extreme ordinates, twice the sum of the intermediate odd ordinates, and four times the sum of the even ones. Multiply the result by the common distance of the ordinates, and one-third of the sum is the area, either accurately or approximately.* A similar rule may be derived from the formula of article 121 for areas such as ABGD.

According to the relation subsisting between the ordinates a_1, a_2, a_3, the equation of art. 119 will be that of a straight line or a parabola; hence the result obtained by the above rule will be strictly accurate in the case of all figures, such as C*ch*H (fig. art. 117), having those portions of their boundaries CDE, EFG, which are terminated by the odd ordinates, either straight lines or parabolic arcs. The curve CEH may therefore be either wholly convex or wholly concave, towards AB, or partly convex and partly concave, provided in the latter case the points of contrary flexure occur only at the odd ordinates; for otherwise the intermediate arcs could not be, even approximately, parabolic. When points of contrary flexure occur, ordinates may be drawn at those points, and the intermediate areas, being found separately, may be added to obtain the whole surface. In other cases where there are numerous points of contrary flexure, the formula of art. 118 will probably give as good an approximation to the area of the curve as that obtained by the more complex formula of art. 121.



Example.—To find the area of a quadrant of a circle. Draw DE bisecting AC at right angles, then BD is an arc of 30°, and the quadrant ABC $=3$ sector DBC $=3\{\mathrm{BCED}-\mathrm{CED}\}$; $\mathrm{DE}^2=\mathrm{DC}^2-\mathrm{EC}^2$, if we put $\mathrm{DE}=a_1$, $\mathrm{F}f=a_2$, &c., we have

$$a_1^2=144-36=108$$
$$a_2^2=144-25=119, \&c;$$

$$\begin{aligned}\therefore\ a_1&=10{\cdot}3923048\\ a_2&=10{\cdot}9087121\\ a_3&=11{\cdot}3137085\\ a&=11{\cdot}6189500\\ a_5&=11{\cdot}8321596\\ a_6&=11{\cdot}9582607\\ a_7&=12{\cdot}0000000\end{aligned}$$

also $h=\frac{1}{6}\mathrm{EC}=1$

The area is then calculated as follows :—

$$\begin{array}{rr} a_2= & 10{\cdot}9087121\\ a_4= & 11{\cdot}6189500\\ a_6= & \underline{11{\cdot}9582607}\\ & 34{\cdot}4859228\\ & \underline{4}\\ & 137{\cdot}9436912\\ a_3= & 11{\cdot}3137085\\ a_5= & \underline{11{\cdot}8321596}\\ & 23{\cdot}1458681\\ & \underline{2}\\ & 46{\cdot}2917362 \end{array} \qquad \begin{array}{rr} a_1= & 10{\cdot}3923048\\ a_7= & 12{\cdot}0000000\\ & 137{\cdot}9436912\\ & \underline{46{\cdot}2917362}\\ & 3)206{\cdot}6277322\\ \mathrm{BCDE}= & 68{\cdot}8759107\\ \mathrm{DEC}=\frac{1}{2}\mathrm{CE}\cdot\mathrm{DE}= & \underline{31{\cdot}1769144}\\ & 37{\cdot}6989963\\ & \underline{3}\\ \text{quadrant}= & 113{\cdot}0969889 \end{array}$$

The quadrant whose radius is unity, obtained by dividing by 144, is ·785396, which is correct to five places of decimals. The area of BCDE, calculated by the rule of art. 118, is 68·8279433 from which the quadrant whose radius is unity, is found to be ·789396, a result correct only to two places.

123. *To find the Volume of a Solid of Revolution.*—The solid is supposed to be generated by the revolution of the figure CEH*hc* (art. 117) about the line AB.

Let ABCD (fig. art. 119) be a portion of the figure (art. 117) such as CE*ec*, terminated by two *odd* ordinates; and assuming EF, FD as axes, let

$$y^2=m+nx+px^2$$

be the equation of a curve of the second degree passing through the points A, E, C. Then if we put

$$\mathrm{AB}=a_1,\ \mathrm{EF}=a_2,\ \mathrm{CD}=a_3, \text{ and } \mathrm{BF}=\mathrm{FD}=h,$$

it will be found, as in art. 119, that

$$m=a_2^2,\ n=\frac{a_3^2-a_1^2}{2h},\ p=\frac{a_3^2-2a_2^2+a_1^2}{2h^2}$$

Hence the volume generated by ABDCE

$$=\pi\int_{-h}^{h}y^2dx=\pi\int_{-h}^{h}(m+nx+px^2)=\frac{\pi h}{3}(a_1^2+4a_2^2+a_3^2).$$

124. A less rigorous demonstration of the same result may also be obtained by assuming that the points A, E, and C, are taken so near each other, that the solid generated by ABDCE differs little from the frustum of a cone; for, by art. 66, its volume will evidently be

$$\tfrac{1}{6}\mathrm{BD}(\pi a_1^2+4\pi a_2^2+\pi a_3^2)=\tfrac{1}{3}\pi h(a_1^2+4a_2^2+a_3^2).$$

125. If now we put in the figure of art. 117 as formerly,

$$\mathrm{C}c=a_1,\ \mathrm{D}d=a_2,\ \mathrm{H}h=a_n, \&c., \text{ and } cd=de=\&c.=h,$$

the volumes generated by CE*ec*, EG*ge*, &c., will be respectively

$$\tfrac{1}{3}\pi h(a_1^2+4a_2^2+a_3^2),\ \tfrac{1}{3}\pi h(a_3^2+4a_4^2+a_5^2)\ \ldots\ldots$$
$$\tfrac{1}{3}\pi h\,(a_{n-2}^2+4a_{n-1}^2+a_n^2).$$

Whence the whole solid of revolution generated by C*ch*H will be

$$\tfrac{1}{3}\pi h\{a_1^2+a_n^2+2(a_3^2+a_5^2+..a_{n-2}^2)+4(a_2^2+a_4^2+..+a_{n-1}^2)\}.$$

Example.—To find the volume of the frustum of a sphere generated by the revolution of BDEC, in the figure to art. 122, we have the values of a_1^2 a_2^2 as follows :—

$$\begin{array}{r} a_2^2=119\\ a_4^2=135\\ a_6^2=\underline{143}\\ 397\\ \underline{4}\\ 1588\\ a_3^2=128\\ a_5^2=\underline{140}\\ 268\\ \underline{2}\\ 536 \end{array} \qquad \begin{array}{r} a_1^2=108\\ a_7^2=144\\ 1588\\ \underline{536}\\ 2376 \end{array}$$

$\therefore$ the volume of the frustum

$$=\frac{\pi}{3}\times 2376$$
$$=2488{\cdot}1413816;$$

which agrees accurately with the value found by the formula of article 81.

126. As it may sometimes be more convenient to measure equidistant circumferences of the solid of revolution than equidistant radii; let $c_1, c_2, \ldots. c_n$, be the circumferences of the circles described by the revolving points C, D, &c. (art. 117).

Then, since $\pi a_1^2=\frac{c_1^2}{4\pi}$, $\pi a_2^2=\frac{c_2^2}{4\pi}$, &c. (art. 56),

the volume of the solid of revolution will be

$$\frac{h}{12\pi}\{c_1^2+c_n^2+2(c_3^2+c_5^2+..+c_{n-2}^2)+4(c_2^2+c_4^2+..+c_{n-1}^2)\}.$$

127. Also, since $\pi a_1^2, \pi a_2^2 \ldots. \pi a_n^2$, are the areas of the circles described by the revolving ordinates $a_1, a_2, \ldots. a_n$, if $s_1, s_2, \ldots. s_n$, be put for these areas, the volume of the solid of revolution will be

$$\tfrac{1}{3}h\{s_1^2+s_n^2+2(s_3^2+s_5^2+\ldots+s_{n-2}^2)+4\,(s_2^2+s_4^2+\ldots+s_{n-1}^2)\}.$$

128. In the figure AEB (art. 117) $a_1=o$, and $a_n=o$; therefore the volume of the solid generated by its revolution

$$=\tfrac{2}{3}\pi h\{a_2^2+a_4^2+\ldots.\ a_{n-1}^2+2(a_1^2+a_3^2+\ \ldots.\ a_n^2)\};$$

and the formulæ of articles 125, 126 may be similarly modified.

The equation of art. 123 may either be that of a straight line, a circle, an ellipse, or a hyperbola, according to the relations which may subsist between the ordinates a_1, a_2, a_3. Hence the formulæ of arts. 124–128 will be strictly accurate for solids generated by the revolution of areas bounded by any of these lines, subject to the limitation stated in art. 122.

129. If the curve which generates the solid of revolution be everywhere convex to the axis of the solid, the volume may be obtained by a somewhat simpler formula than that of art. 124.

Let the base of the figure be divided into *any* number of equal parts by the ordinates $a_1, a_2, \ldots a_n$, whose common distance is h.

Then if a parabola be described passing through the points AE (fig. art. 119), and whose axis is the line BF, it will coincide either nearly or exactly with the curve AE; and by art. 111 the paraboloid generated by AEBF,

$$=\tfrac{1}{2}\pi(a_1{}^2+a_2{}^2)h.$$

Similarly if another parabola be described passing through the points E and C, the volume generated by ECDF

$$=\tfrac{1}{2}\pi(a_2{}^2+a_3{}^2)h.$$

Therefore proceeding as in art. 125, the volume of the whole solid of revolution

$$=\tfrac{1}{2}\pi h\{a_1{}^2+a_n{}^2+2(a_2{}^2+a_3{}^2+\ldots\ldots+a_{n-1}^2)\}.$$

Example.—The volume of the segment of a sphere which is calculated in the example to art. 124, may be found as follows:—

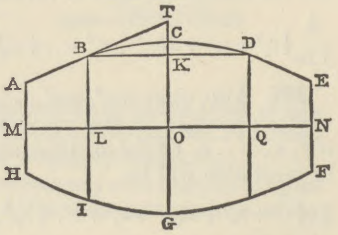
$$\begin{array}{rl}
a_2{}^2=119 & \quad a_1{}^2=108 \\
a_3{}^2=128 & \quad a_7{}^2=144 \\
a_4{}^2=135 & \quad \phantom{a_7{}^2=}1330 \\
a_5{}^2=140 & \quad \phantom{a_7{}^2=}\overline{1582} \\
a_6{}^2=143 & \\
\overline{665} & \quad \therefore \text{volume}=\frac{\pi}{2}\times 1582 \\
2 & \quad \phantom{\therefore \text{volume}}=2485 \text{ nearly.} \\
\overline{1330} &
\end{array}$$

130. *To find the Volume of any Solid.*—Let $s_1, s_2, \ldots s_n$, be the areas of equidistant sections, taken so near each other that every two consecutive sections may be regarded as sensibly similar. Then, since it has been proved in art. 39 that the volume of any prismoidal solid, of which $s_1{}^2, s_2{}^2, s_3{}^2$ are the areas of the ends and middle section, and h half the height, is $\frac{1}{3}h(s_1{}^2+4s_2{}^2+s_3{}^2)$; if we proceed as in art. 125, we shall find that the volume of the solid is expressed by the formula of art. 127, which therefore applies not only to solids of revolution, but approximately to all solids whatever.

ON GAUGING.

Gauging denotes the measurement of casks or of substances liable to excise duties.

To Compute the Contents of a Cask from its Length and Diameters at the Middle and End.—Let the axis of the cask MN be trisected in L and Q; then the usual form of a cask is such that we may assume AB, DE to be straight lines, and BCD the arc of a parabola whose axis is CO. The portions of the cask AI, DF will then be frusta of cones, and DI will be the frustum of a parabolic spindle.



Put $CG=a$, $AH=b$, $BI=c$, and $ML=LQ=QN=\frac{1}{3}l$. Then the volume generated by AL or DN

$$=\frac{\pi l}{180}(5b^2+5bc+5c^2)\ (\text{art. } 65);$$

and the volume generated by BQ

$$=\frac{\pi l}{180}(8a^2+4ac+3c^2)\ (\text{art. } 113).$$

Now if AB be produced to T, because TB is a tangent to the parabola BC, TK = 2CK, and by similar triangles

$$\text{TK} : \text{BL}-\text{AM} :: \text{BK} : \text{ML}, \text{ or } 2(a-c) : c-b :: 1 : 2;$$

from which $c=\frac{1}{5}(4a+b)$. Therefore substituting for c, and adding, we obtain the whole content of the cask

$$=\frac{l}{360}(39{\cdot}04a^2+25{\cdot}92ab+25{\cdot}04b^2)$$

$$=\frac{\pi l}{360}(39a^2+26ab+25b^2) \text{ nearly.}$$

If a, b, and l are expressed in inches, since there are 277·3 cubic inches in a gallon, and

$$\frac{\pi}{360\times 277{\cdot}3}={\cdot}000031470,$$

the contents of the cask in imperial gallons

$$=l(39a^2+26ab+25b^2)\times{\cdot}00003147 \quad . \quad . \quad (1.)$$

Again, because $39a^2+26ab+25b^2$

$$=(39a^2+26ab+26b^2)\left(1-\frac{b^2}{39a^2+26ab+26b^2}\right);$$

and since b is generally about $\frac{3}{4}a$,

$$1-\frac{b^2}{39a^2+26ab+26b^2}=1-\frac{1}{129}=\frac{128}{129};$$

therefore the content of the cask in gallons

$$=l(39a^2+26ab+26b^2)\times\frac{128}{129}\times{\cdot}0003147$$

$$=l(\tfrac{2}{3}a^2+ab+b^2)\times{\cdot}000812 \text{ nearly} \quad . \quad . \quad . \quad (2.)$$

Example.—Let the bung and head diameters of a cask be 32 and 24 inches respectively, and its length 40 inches; required its content in gallons.

By formula (1) the content

$$=(39\times 32^2+25\times 24^2+32\times 24\times 26)\times 40\times{\cdot}00003147$$

$$=93{\cdot}29 \text{ gallons.}$$

By formula (2) the content

$$=(\tfrac{2}{3}\times 32^2+24^2+32\times 24)\times 40\times{\cdot}000812=93{\cdot}54 \text{ gallons.}$$

The contents of casks of any forms to which the preceding formulæ may not apply, may be determined with great accuracy by the following method.

If a and b be the bung and head diameters, c the diameter equidistant from the bung and head, and l the length of the cask, all in inches, it is obvious, by article 124, that the capacity of the cask in gallons

$$=\frac{\frac{1}{4}\pi l}{3\times 4\times 277{\cdot}3}(2a^2+2b^2+8c^2)$$

$$=l\{a^2+b^2+(2c)^2\}\times{\cdot}00047205.$$

Example.—Let the bung and head diameters be 32 and 24, the middle diameter 30·2, and the length of the cask 40. The capacity

$$=40\times\{(32)^2+(24)^2+(60{\cdot}4)^2\}\times{\cdot}000472=99{\cdot}1 \text{ gallons.}$$

To find the Ullage of a Cask.—The quantity of liquor contained in a cask partially filled, and the capacity of the portion which is empty, are termed respectively the wet and dry ullage.

(i.) The ullage of a standing cask is found by the method of article 124 as follows:—

Add the square of the diameter at the surface, the square of the diameter at the nearest end, and the square of double the diameter half way between; multiply the sum by the length between the surface and the nearest end, and by ·000472. The product will be the wet or dry ullage, according as the lesser portion of the cask is filled or empty.

(ii.) The ullage of a lying cask is found approximately on the assumption that it is proportional to the segment of the bung circle cut off by the surface of the liquor. The rule adopted in practice is,

$$\text{ullage}=\tfrac{5}{4}\text{ content of cask}\times\text{segmental area.}$$

(W. S.)

MENTAL DISEASES.

MENTAL DISEASE, MENTAL DERANGEMENT, or MENTAL ALIENATION, comprises two great and distinct classes of morbid affections of the mind,—the one, the result of disease attacking a person of sound mind, is called *Insanity* or *Lunacy;* the other, the result of original or congenital conditions of the individual, is called *Idiocy*, or, in its lesser degrees, *Imbecility*.

All modern physiologists are agreed in regarding the brain as the organ of the mind; it may therefore be stated that these diseases result from affections of the brain,—the one class (insanity) resulting from diseases of a brain originally healthy; the other (idiocy) arising from original defects in the brain, such as imperfect development, or congenital disease of that organ.

Definitions.

Many attempts have been made to define insanity and idiocy; but as the varieties of the mental diseases classed under those general terms are so numerous, and their distinctions in some instances so great, and in others so minute, it may be questioned whether it is possible to define either so as to make the definition of any practical value. Accordingly, most definitions will be found to be either so general and comprehensive as to include sane persons, or so circumscribed as to exclude many who are of unsound mind. Those definitions which will bear criticism will be found to be too general to be of practical use, and to amount to little more than is conveyed in the terms mental derangement or unsoundness. A brief review of the subject will make this apparent, and serve to show in what manner insanity and idiocy can be best described and defined for all legal and practical purposes.

The celebrated Locke incidentally remarked that "madmen do not appear to have lost the faculty of reasoning; but having joined together some ideas very wrongly, they mistake them for truths, and they err, as men do that argue right from wrong principles." Idiots, on the other hand, do not labour under delusions, or mistake mere ideas for truths, but they reason imperfectly. It has accordingly been said that the insane reason rightly from false premises, and idiots reason falsely from right premises. It was the fashion to consider this a definition of insanity and idiocy. But it is obviously no definition at all, as it would include all careless observers among the insane, and consign all illogical reasoners to the category of idiots. Almost all attempts at a definition of insanity, both by medical writers and legal authorities, have been founded on the same idea which occurred to Locke,—namely, that in every case of insanity there was some delusion, and that delusion was, in fact, an essential feature of insanity. This continues to be generally believed even at the present day, and has been laid down in our courts of law authoritatively from the bench. Proceeding upon this assumption, Dr Cullen defined insanity to consist in erroneous or false judgment; and Dr Haslam, to obviate the objection to this as a definition, that some people also make errors in judgment as to facts, added to the definition the impossibility of convincing the insane that this false judgment, error, or delusion, was a delusion. Dr Prichard rendered the definition more precise in his work on "Nervous Disorders," by defining insanity to consist in the conceptions of the mind being mistaken for realities.

More recent authorities have introduced another element into their definitions of insanity,—namely, the loss of self-control—of moral liberty. Thus, M. Morel, one of the latest French writers on insanity, defines it as "une affection cérébrale idiopathique ou sympathique enlevant à l'individu lésé à la fois dans ses fonctions physiologiques et psychologiques, l'exercice de sa liberté morale, et constituant dès lors chez lui une depravation maladire dans ses actes, ses tendances, et ses sentiments ainsi qu'un trouble général ou partiel dans ses idées" (*Etudes Cliniques*, Morel, p. 214). And Mr Noble, the author of the latest systematic work on insanity published in this country, defines it to consist in "chronic disorder of the brain inducing perversion of ideas prejudicial to, or destructive of, the freedom of the will."

The impairment or loss of the power by which we regulate our actions, or the succession of our thoughts, or our judgment regarding external objects or conceptions of the mind, is certainly the most essential peculiarity of insanity; but this seems to be something different from the loss of moral liberty, or the destruction of the freedom of the will. Further, all these definitions seem to assume that there must be some perversion of the understanding—some *delusion* in insanity. This is by no means the case. Nothing is now more fully demonstrated in relation to the insane than this, that there are many cases in which there are no delusions, erroneous impressions, or false judgments, but in which a morbid and ungovernable passion, emotion, or impulse, constitutes the disease. The late Dr Abercrombie was nearer the truth when he described insanity to consist in the undue (morbid?) exercise of one or more powers or faculties of the mind; and idiocy (including dementia) in the deficient exercise or power of the mental faculties. The one consists in a loss of balance; the other in a loss of power,—terms, however, too general for the purposes of a definition.

Assuming that insanity is a disease of the brain, and making provision for cases in which there are no delusions,—cases of what is called moral insanity,—the following definition appears to be as precise as any that can be arrived at;—namely, that it is a chronic cerebral affection, in which emotions, passions, or desires are excited by disease (not by motives), or in which conceptions are mistaken for acts of perception or memory.

This definition distinguishes two classes or general forms of insanity,—one in which the emotions, passions, or desires alone are affected, constituting cases of moral insanity. There may be a general perversion of the emotions and passions without delusions, or a morbid excitement of one particular emotion or passion. In the one case the disease is called mania, or general madness; in the other, monomania or partial insanity.

In the same way the second part of the definition includes those cases in which there may be a general perturbation of the ideas or understanding, general excitement, and incoherent raving on a variety of subjects, referable, therefore, again to mania or general insanity; and also cases in which there is a perversion only in particular trains of thought, or in reference to one object, and referable therefore to monomania or partial insanity. The various forms of insanity are thus arranged in two great classes,—moral and intelligential, or emotional and notional; and in either of these classes it may be either general (mania) or partial (monomania).

The loss of self-control, and of the power of directing the thoughts or correcting the judgment by an act of volition, is an important feature of insanity, and probably constitutes the proximate psychological cause of the mental condition of the insane. As was remarked by Dugald Stewart, the insane are very much like persons asleep, by whom the objects of reverie, and the conceptions which pass through their minds, are believed at the time to have a real existence, because they cannot correct their judgment regarding them by voluntarily referring to the objects by which they are surrounded, as persons do when awake. Thus, in dreams all the persons we see are really believed to be actually before us; the events which are apparently taking place fill us with pleasure or terror according to their character, because they are believed to be realities. Is it not so with the insane? Is it not the suspension of some power of volition, self-direction, or judgment, which makes the insane the sport of their passions and desires, and gives rise in them to the belief in the extraordinary delusions which fill them with ecstasy, terror, or despair?

Idiocy can only be defined in very general terms as a congenital mental deficiency. The degrees of this deficiency are infinitely varied, from the total absence of anything like human thought or reason up to the smallest amount of imbecility which distinguishes a naturally weak-minded person from one of sound mind.

Historical retrospect.

The history of some sciences and arts may with propriety be consigned to oblivion as the cumbrous record of ignorance and error; but the history of this department of study is that of the development of the human mind,—of man himself,—and is therefore deserving of study. The philosophy of mind, and by consequence that of mental diseases and their treatment, has, moreover, by no means attained even at the present day such precision as to render the opinions of previous authors uninteresting or superfluous. (Feuchtersleben, *Principles of Medical Psychology*, p. 23.) A brief historical sketch of the subject may therefore be both instructive and interesting.

The most ancient historical records prove that insanity was recognised in the earliest times. The Israelites were threatened with "madness, and blindness, and astonishment of heart for their transgressions" (Deut. xxviii. 28). David feigned madness before Achish the King of Gath (1 Sam. xxi. 13); and what is more curious, he alleviated the fits of madness to which Saul was subject by his skilful playing on the harp. The influence of music, and of those distractions so much lauded in the present day for the treatment of the insane, appears to have been also well understood by the priests of ancient Egypt. There the temples of Saturn were resorted to by crowds of melancholics. "Whatever gifts of nature or productions of art were calculated to impress the imagination were there united to the solemnities of a splendid and imposing superstition. Games and recreations were instituted in the temples. The most voluptuous productions of the painter and the statuary were exposed to public view. Groves and gardens surrounded those holy retreats, and invited the distracted devotee to refreshing and salubrious exercise. Gaily-decorated boats sometimes transported him to breathe amidst rural concerts the purer breezes of the Nile. In short, all his time was taken up by some pleasurable occupation, or rather by a system of diversified amusements, enhanced and sanctioned by superstition." (*Nosographie Philosophique*, Pinel, tom. ii. 28; Pinel *On Insanity*, by Dr Davis, Introduction, p. xxii.) From the hands of the priests the care of the disordered mind first passed into the domain of medicine with the philosophers of ancient Greece. Pythagoras is said to have employed music for the cure of mental diseases. The order of the day for his disciples exhibits a profound knowledge of the relations of body and mind, and constitutes a most complete system of mental dietetics. The early morning was divided between gentle exercise and reflection, music and study; then came conversation, followed by gymnastic exercises, and a simple and temperate diet; attention to public affairs succeeded, followed again by walking and cheerful conversation, and afterwards a cold bath and supper, with a sparing allowance of wine; and then reading, music, and reflection, concluded the day.

The formation of medical schools in Greece by the disciples of Pythagoras completed the transfer of the sick and insane from the trammels of superstition and priestcraft, consolidated medicine into an art, and, in the department of psychology at least, the philosophy of the Greeks elevated it to the rank of a science. The treatment of mental disorders by Asclepiades, as described by Celsus and Aurelianus, might almost be taken for an epitome of the modern method. "Music, love, and wine, employment exercising the memory and fixing the attention, were his principal remedies. He recommended that bodily restraint should be avoided as much as possible, and that none but the most dangerous should be confined by bonds. He was peculiar in advising that the lunatic patient should be engaged in the self-regulation of his mental powers." (Feuchtersleben, *op. cit.*, p. 36.)

Of the opinions of Hippocrates, the father of medicine, on the subject of insanity, although contemporaneous with Asclepiades, we know less, but yet enough to satisfy us that he was a careful observer of the phenomena of that disease.

The philosophy and the arts of Greece spread to Rome, and the first special treatise on insanity is that of A. Corn. Celsus, which distinguishes several varieties of insanity and their appropriate treatment. Aretæus of Cappadocia describes in graphic terms many additional varieties of the disease, with their causes and prognostics. He and Aurelian both laud the psychiatrical treatment of Asclepiades. Lastly, Galen, with all his learning, appears to have added little to this department of medical observation and treatment.

Over the arts and sciences of Greece and Rome the errors and ignorance of the middle ages gradually crept, until they enveloped them in a vast cloud of worse than Egyptian darkness. The insane, if treated at all, were again consigned to the miracle-working artifices of priests, or else totally neglected. Idiots and imbeciles were permitted to wander about clotheless and houseless, the sport of the wanton and wicked thoughtlessness of children; the frantic and furious were chained in loathsome dungeons, and exhibited for money like wild beasts; the monomaniacs became, according to circumstances, the objects of superstitious horror or reverence; they were regarded as possessed with demons, and subjected either to priestly exorcisms, or cruelly destroyed as wizards and witches; at other times they were made the tools of the designing and ambitious, and, as inspired instruments of the Deity, became the leaders of revolutions and revolts. Vast epidemics of insanity spread over Europe at various periods of the dark ages; lycanthropy, vampirism, the Crusades, the dancing mania, the pilgrimage mania of children, St Vitus' dance, and various other epidemics, followed each other in successive generations. The total neglect or cruel treatment of the insane continued, with little or no alleviation, down to the end of the last century in all the civilized countries of Europe. The revival of learning,—nay, even the reconstruction of medical science,—shed no ray of light upon the unhappy victims of this disease.

During all this period, then, our subject can scarcely be said to have a history. At best it is but the history of scholastic disputations regarding the soul and the supposed humours of the body, or a history of the demonomaniacs of those times, the trials for witchcraft, and the wide-spread massacres which followed; or a history of the epidemics referred to, or of the neglect and cruelty with which the helpless idiots or furious maniacs of all countries were treated.

With the metaphysical speculations of Locke and Leibnitz, followed by those of Bonnet, Condillac, and the Scottish school of metaphysicians, appears to have originated the first impulse to the study of the subject from its purely psychological side. Added to this, came the doctrines of Stahl, which laid the basis for a psychological and practical view of it, which gradually acquired solidity and system from the researches into the anatomy of the brain and nervous system by Soemmering, Reil, Meckel, and Gall. During all this period, however, to which we can only allude, no practical results followed as regarded the treatment of the insane. Public asylums, indeed, existed in most of the metropolitan cities of Europe; but the insane were more generally, if at all troublesome, confined in jails, where they were chained in the lowest dungeons, or made the butts and menials of the most debased criminals. Even in the public asylums, many of which were endowed by the munificence of philanthropists, the inmates were generally confined in low and damp cellars, sometimes isolated in cages or chained to the floor or wall; if harmless, they were huddled together, without regard to their habits, in cells not fitted to contain one tithe of the number immured in them. The medical treatment consisted, perhaps, in an annual bleeding and a few emetics; while the lash was systematically used, justified, and even recommended, as it had been by such authorities as the celebrated Cullen. These unhappy victims of disease were exhibited to the public like wild beasts, and their passions irritated to gratify a morbid and vulgar curiosity. They were often killed by the ignorance and brutality of their keepers, sometimes during rough methods of forcing meat into them, sometimes by barbarous and violent beating.

Such was the state of the insane generally throughout Europe at the commencement of this century; such it continued to be in England so late as 1815, and in Ireland in 1817, as revealed by the inquiries of parliamentary commissions in those years respectively; such it doubtless was also in Scotland, as the report of the commission appointed in 1855, showing the neglected condition of the pauper insane even at the present day, abundantly testifies. Indeed it cannot be doubted that in many countries of Europe the insane are little, if at all, better cared for even now, especially in rural and remote districts.

The greatest step in the amelioration of the condition of the insane originated in Paris with the illustrious Pinel, who immortalized his name by liberating all the inmates of the Bicetre from their chains in 1792. The success attending his philanthropic efforts speedily led to great changes in the treatment of the insane; and his distinguished successor Esquirol endeavoured to extend the same humane principles of treatment to all the asylums of France. One of the earliest institutions of this country to adopt the humane system of treatment was one belonging to the Society of Friends near York, called the Retreat, where, under the auspices of William Tuke, not only were chains, stripes, and cruelty abolished, but the most enlightened principles of moral treatment were adopted. The attention directed to the subject by the published account of the Retreat (1813) speedily led to the introduction of the law of kindness into some of our large public asylums. In the Lincoln Asylum mechanical restraint of every kind was abolished (1836). In the large asylum of Hanwell, Dr Conolly soon afterwards, in spite of many obstacles, succeeded in carrying out the principle of non-restraint with remarkable success; and he has continued to this day to advocate the complete abolition of all mechanical restraint in the treatment of the insane in public asylums, with a devotion and eloquence which has contributed very largely to the adoption of this principle throughout the county asylums of England. The reports of the parliamentary committee (1815, 1816) led to the appointment of a permanent lunacy commission in England, under the auspices of which a number of new county asylums were erected, and in these the principles of non-restraint, and the improved moral treatment of the insane, were carried out and developed. Similar results gradually followed a parliamentary inquiry into the condition of the insane in Ireland (1817). In Scotland the philanthropic efforts of a few individuals led to the erection of several public or chartered asylums in the early part of the century; and in most of these (Edinburgh, Glasgow, Dundee, Dumfries) at an early period, (1840-42) not only was mechanical restraint almost entirely abolished, but a great variety of moral appliances were introduced, such as schools, lectures, concerts, dramatic representations, social entertainments, periodicals written, and in some instances printed, by the patients, excursions to the country, and numerous sources of healthy occupation. If Scotland is still behind the sister countries, in consequence of the want of a legal provision for her insane paupers, she may well be proud of what has been achieved by the spontaneous efforts of the benevolent, and of the admirable manner in which her public asylums have been conducted. In the multitude and variety of the moral appliances for the cure and alleviation of insanity in use in those institutions, she has been in advance of most of the public asylums of either England or Ireland. The hospitals for the insane which have been erected in the various states of the North American republic during the last twenty years, have also been organized and conducted upon the most approved and enlightened principles of modern science: in them everything that can minister to the mind diseased, by distracting it from morbid trains of thought,—the influences of literature, and science, and music, and recreation,—have been added to the salutary regimen and judicious medical treatment of well-arranged and well-regulated hospitals.

Accompanying and assisting in this onward movement we find valuable works on insanity appearing on the Continent and in this country, of which a list is appended to this article. An agent, not less important in the dissemination of all the improved methods of treating the insane, was found in the annual reports of the best public asylums; and of those deserving of especial notice may be enumerated the reports of the Retreat, of Lincoln Asylum, of Hanwell, of the Northampton, Lancaster, Gloucester, and Stafford asylums, and of the Scottish chartered asylums, particularly those of Edinburgh, Glasgow, Dundee, and Dumfries, in all of which the rapid progress of psychological medicine, in its humane and moral aspects, was early and most fully represented. The reports of the excellent county asylums more recently established in England, those of the American asylums, and, lastly, the valuable reports of the Commissioners on Lunacy, have all contributed largely to the spread of the new and improved methods of treatment. Another and important agent in this cause has been the establishment of journals specially devoted to medical psychology. The first of these appeared in Germany in 1806-1808; then followed *Nasse's Journal* (1818–1826); Friedereich's *Magazine* (1829–1838); and, lastly, Dameron and Fleming's *Allegmeine Zeitschrift für Psychiatrie* (1843). In France the *Annales Medico-Psychologiques* (1841); in America the *American Journal of Insanity* (1844); and in England Dr Winslow's *Journal of Psychological Medicine* (1848); and, lastly, the *Asylum Journal* (1853), successively appeared, and continue to be published.

Idiocy.

Special attention to the care of idiots has been a matter of comparatively recent date. The establishment of schools for their education, and the development of their latent or imperfect faculties, first attained considerable success under M. Séguin at Paris. (*Traitement Moral Hygiène et Education des Idiots*, par Edouard Séguin, Paris, 1846.) Dr Gügenbuhl simultaneously (1840) established, under the auspices of the Swiss government, an institution for the *cure* of cretinism at Interlacken, on the Abenberg, where, by commencing their treatment in infancy, it is said that those congenital diseases upon which this condition depends have been cured. The interest excited by the philanthropic labours of this physician has led to inquiries into the condition of idiots in various countries. A commission of inquiry investigated the subject fully in Sardinia (*Rapport de la Commission pour etudier le Crétinisme*, Turin, 1848), where, as also in Austria, Prussia, Würtemberg and Saxony, Bavaria and Baden, institutions for idiots have been established. A careful inquiry, under the direction of Dr Howe, was made into the number and condition of the idiot population in Massachusetts (U. S.), and a school was established there for their benefit. Lastly, in England, at Bath, and afterwards at Highgate near London (1847), and more lately at Dundee and Edinburgh (1855), medico-educational establishments for idiots have been instituted, and promise to confer great benefits upon this interesting and helpless portion of the human family.

In concluding this brief historical retrospect, we cannot refrain from expressing our surprise that the study of mental diseases has been deemed of so little interest or importance hitherto, as to form no part of the curriculum of medical education in this country. Although the large metropolitan asylums afford ample means of illustrating courses of instruction in psychological medicine, the study of the subject has never been required by our licensing medical or surgical boards or universities. Lectures on mental diseases, both systematic and practical, have indeed been delivered in many of the continental medical schools; and of late years, in some of the large asylums of London and in that of Edinburgh, clinical lectures have been given; but attendance upon such courses of instruction is voluntary, with the exceptional case of candidates for appointments in the H.E.I. Company's service, who have been required during the last four years to attend an asylum for the insane for three months. This neglect seems altogether unaccountable, when we reflect upon the many collateral sciences students of medicine are compelled to master, of comparatively little value to them in actual practice, and the many diseases, accidents, and operations, toxicological and analytical investigations, they are carefully and minutely schooled in, which it may never fall to their lot, in a long life, to see or practise; while insanity, which affects 1 in every 400 or 500 of the population, and which, in some of its stages or forms, they can hardly pass a week in medical practice without being consulted about,—often in circumstances requiring great judgment and skill,—is made no part of their medical education at all.

Classification. A variety of methods have been proposed for classifying the different forms of insanity. Without entering into a critical examination of these methods, it may be sufficient for the purposes and limits of this article to give what appears to be a comprehensive and convenient classification, and one as nearly as possible in conformity with the terms in common use among writers on insanity at the present time.

Insanity consists either in a general or partial exaltation or morbid excitement of the faculties, or an impairment of them to a greater or less extent; and we have accordingly three great divisons of the subject,—*Mania*, *Monomania*, and *Dementia*, under each of which there fall to be arranged various modifications, subdivisions, and complications; and, lastly, we have *Idiocy*, consisting in a natural want of development of one or more or of all the mental faculties. The following table exhibits this classification, with the subordinate subdivisions referred to:—

I. MANIA.—*General Derangement of the Faculties.*

Acute	Affecting the emotions and passions only:—*Moral Insanity.* Affecting the intellectual faculties also, *generally*:—*Mania* or *Raving Madness.*
Chronic	
Periodic	
Remittent	

Puerperal Mania.
Delirium Tremens.

II. MONOMANIA.—*Partial Derangement of the Faculties.*

Melancholia	ffecting the desires, emotions, or passions only, without delusion:—*Moral Insanity.* Affecting the intellect or understanding, with delusions, illusions, or hallucinations:—*Intellectual* or *Notiona Insanity.*
Suicidal Mania	
Homicidal Mania	
Kleptomania	
Pyromania	
Dipsomania	
Satyriasis	
Nymphomania	
Monomania of Pride	
... Fear	
... Suspicion	
... Unseen Agency	

III. DEMENTIA.—*Obliteration of the Faculties.*

1st Stage.—Forgetfulness—loss of memory—senile dementia.
2d ... Irrationality—loss of reason—marked incoherence.
3d ... Incomprehension—instinctive stage—fatuous.
4th ... Inappetency—loss of instinctive action—total fatuity.

General Paralysis with *Insanity.*
Epilepsy with *Insanity.*

IV. IDIOCY.—*Non-Development of the Faculties.*

Imbecility.
Idiocy.
Cretinism.

I.—MANIA.

The most striking features of *acute mania* are the exaltations of the emotions, or, as it is commonly termed, the excitement of the patient, the incoherence of his ideas, the restlessness and agitation of his movements and gestures, and the volubility and energy of his language. The invasion of mania is sometimes sudden, and the disease is at once developed by an outburst of violence or excitement. Most frequently, however, it is preceded by some premonitory symptoms, of which the most frequent is the want of sleep; so constant indeed is this harbinger, that a distinguished American writer (Dr Brigham) regarded it as *the cause* of insanity. This sleeplessness is generally accompanied by loss of appetite and derangement of the digestive functions. The patient often complains of headache, confusion, and fear of going mad. He displays irritability of temper and impatience of contradiction or interference. He is unusually active, and full of new projects and ideas. His settled habits become altered; he neglects duties heretofore punctually discharged, or becomes suddenly an attentive observer of duties before neglected. Not unfrequently he uses stimulants to excess, although before temperate in his habits. His affections are altered or perverted; he dislikes his nearest friends, and views all their acts with suspicion and distrust. After these symptoms have gradually manifested and developed themselves during a period of a few days or weeks, he ultimately loses the power of self-control, and his conduct becomes violent, or his ideas and conversation incoherent, or both. In the former case he destroys his clothing, strips himself naked, dresses his naked body fantastically with strips of his blankets, besmears himself with filth, talks incessantly and vociferously, walks up and down, or flings his arms, or tumbles his person about without ceasing. His conversation is characterized by wit, or violence, or obscenity. All these symptoms may exist without any delusions or any incoherence of thought; but on the contrary the individual may display great acuteness, intelligence, and wit, combined with any conceivable amount of excitement, activity, obscenity, and destructiveness. Such a variety of mania belongs, then, properly to that kind of madness called *moral insanity;* the emotions and passions being in a general state of exaltation or excitement beyond the powers of self-control, but without delusions affecting the intellect. Most frequently, however, in a mania, the ideas succeed each other without any apparent order, and the patient raves or talks incoherently. Or some delusion seizes his imagination, and, according to the nature of it, he is affected with extravagant anger, joy, or terror. He is surrounded by foes on whom he seeks to vent his rage; or he is about to be married; or has become heir to enormous riches and to titles of high rank; or he imagines he is a divine being endowed with supernatural powers, and he calls down vengeance on all who oppose him; or he fancies he is surrounded by objects of fear, by fire, and blood, and demons, and he cries out with the utmost terror at the objects of his disordered vision. There may thus, in those cases where the intellect is affected, be only excessive activity of thought, producing rambling and incoherent conversation; or there may be *delusions*—the belief in the creations of the imagination; or there may be *illusions*—the belief that sounds or objects are other than they really are; or, lastly, *hallucinations*, or the actual perception, by the diseased organs of sense, of objects, of persons, and things, and sounds, which have no real existence.

The most essential and characteristic feature of acute mania appears to be the loss of self-control,—1. Over the voluntary acts, resulting in violent and excessive restlessness, walking to and fro, wild, extravagant, bizarre gestures, attitudes, and gesticulations. 2. Loss of control over the feelings, emotions, and passions, which are sudden, impulsive, violent, and varied in intensity and character. 3. Loss of control over the ideas, which appear to succeed each other without any order or law of succession, following neither the laws of association nor those of volition, and being therefore rambling and incoherent. The maniac cannot fix his attention; he hardly sees or recognises external objects; he is carried away by ideal terrors, and is the sport of his own diseased imagination. He confounds time and space, and persons and things, and himself, and is lost in an endless whirl of delirium. There is a total overthrow of the moral sense, the loss of all affection, of all regard to religion, or probity, or decency: even the commonest instincts of nature disappear in the total overthrow of all that is human and natural.

During all this time, however, the patient retains a certain consciousness of self; he may, at least for a moment, be brought to fix his attention and answer a question. After his recovery he may even be able to tell all that passed through his mind, all the delusions and hallucinations that haunted him, the attentions he received, the words addressed to him, and the feelings which influenced him in all his actions.

The countenance is remarkably altered in maniacs: it becomes dark and contracted; the eyes are brilliant, injected, and haggard, and expressive of suspicion,—wandering, but watchful; the sense of hearing is often rendered very acute; the tongue is dry and foul, and the patient is devoured by thirst; the appetite is at one time voracious, and at another seems lost; the skin is dry and greasy, and exhales a disagreeable odour; the cold and fatigue, to which they appear (only) to be insensible, affects them equally with other persons, and they sink exhausted under their own violence and incessant activity, or may die of pneumonia or other diseases if unnecessarily exposed to cold. The pulse is generally small, weak, and frequent; and the excretions diminished or irregular.

The habits of maniacs are very offensive. None are more constant than the tendency to go naked, to tear all articles of clothing, bedding, and furniture, and to indulge in the most filthy and shameless practices and language.

The course of an attack of acute mania is very variable and uncertain; sometimes it is transient, and may not exceed twenty-four hours, or from three to five days. This, however, is rare. A remission frequently takes place within the first week, and after a brief tranquillity a fresh outburst of excitement occurs. The average duration of cases of acute mania has been estimated at six weeks.

Remittent mania.

In some cases a frequent remission continues to take place, followed always, sooner or later, by recurrence of the excitement. These are called cases of *remittent mania.*

Periodic mania.

In other cases these remissions and aggravations occur at regular intervals of time,—every month, every two, three, or six months, or every year; and these constitute *periodic mania.*

Chronic mania.

Again, the maniacal excitement continues with more or less amelioration, but still presenting some of the more characteristic features of mania, such as noise, violence, and destructiveness, for many months, or even years, and is then called *chronic mania.*

The curability of mania has been variously estimated at from 70 to 90 per cent. by different authorities. Although the most alarming and unmanageable, it is the most curable form of insanity.

The recovery is generally gradual, with occasional exacerbations: the patient sleeps, becomes stouter in person, gives up his destructive habits, becomes tidy in his dress, and slowly recovers, sometimes exhibiting a certain amount of reaction in a prolonged depression and want of confidence in himself. Sometimes, though rarely, the recovery is sudden; occasionally it is accompanied by some critical termination, as it has been termed, such as the reappearance of some suppressed discharge or eruption, or the formation of large boils.

If the patient does not recover, the disease passes into some other form,—either into chronic or partial insanity, or more frequently into dementia; or he may die from exhaustion or the supervention of some fatal disease.

Puerperal mania.

PUERPERAL MANIA differs little from the disease described, except in the fact that it is peculiar to females after parturition, and, strictly speaking, occurs within a month after delivery. It has been confounded with hysterical mania, with mania occurring during pregnancy, and with insanity developed after prolonged nursing. But in all these cases the disease more generally assumes some of the forms of partial insanity, and does not differ from such diseases arising from other causes. In puerperal insanity the homicidal impulse is not unfrequently developed; and unless the mother is watched, or the child removed, the offspring may be destroyed by its unconscious and delirious parent.

Delirium tremens.

DELIRIUM TREMENS is another form of mania (*mania à potu—brain fever*), arising from the continued and intemperate use of stimulants. It may be termed a kind of alcoholic poisoning, arising from the accumulation of alcohol in the system. It has also been ascribed to the intemperate use of other narcotics, such as opium. The symptoms are in some respects peculiar. The delirium is generally one of alarm, of fear of robbers and murderers, and is accompanied commonly with hallucinations of vision, and with trembling of the limbs, copious sweating, and tendency to exhaustion. Its course is short, and it terminates either favourably or fatally within a few days; and in some cases, where the immediate danger and violent symptoms are recovered from, permanent lesions remain in some form of partial insanity.

II.—MONOMANIA

Monomania.

Was a term invented by Esquirol to designate cases of partial derangement; the ancient name, *melancholia* being inapplicable, in its modern signification, to those varieties where there was no depression of spirits. The term melancholia (*lypemanie*) he reserved for cases where there was a true melancholy or depression, and monomania for other varieties of partial insanity. As all, however, are cases of partial derangement, all of them may be included under this general term, and we may consider therefore melancholia as one of the varieties of monomania.

The general term monomania implies that the individual is deranged only on one subject, or in reference to one object, or in one particular train of thought or faculty of thinking, and that his intellect, judgment, and emotions are otherwise sound, at least when not exercised on the subject of his derangement. This, however, is not, strictly speaking, true. There are exceptional cases in which persons have appeared to retain all their intelligence and reason, and every mental faculty, in a state of healthy exercise, except in reference to one point; but such cases are very rare, and it is doubted whether, upon a close acquaintance with such persons, we would not discover other points of insanity besides the one prominent and characteristic one. In almost all cases of so-called monomania there are other morbid indications besides the salient one,—morbid dislikes or suspicions, morbid vanity or irritability; sometimes other delusions, sometimes hallucinations of the senses. Still there is generally some one morbid impulse or delusion sufficiently prominent to form the principal and characteristic feature of the case, and to make the name of monomania applicable and convenient, and accurate enough for the general purposes of a classification.

It may be observed further, that almost all cases of partial insanity (monomania) may be referrible either to the category of *moral insanity*, when an emotion, passion, or desire is morbidly excited without any delusion; or they may be referrible to *notional* or *intellectual insanity*, when there are certain delusions. This distinction pervades most of the varieties, and will be illustrated immediately in describing the first variety of monomania.

Premonitory symptoms.

Monomania is always preceded by some premonitory symptoms. Its invasion is seldom, like that of mania, sudden. It is emphatically a chronic affection, compared with mania, and produced generally by the continuous operation of some deleterious influences. In almost every case there exists a hereditary predisposition to insanity, and the attack is preceded by some derangement of the general health;—in some cases it coincides with the development of scrofulous or pulmonary disease; in others it is the result of moral causes affecting the health, such as domestic anxieties, retired and secluded habits, reverses in fortune, disappointments in love or in business. The invasion of the malady is commonly preceded by sleeplessness, by altered habits,—the individual becoming irritable, suspicious, impatient of interference, doing odd things; the wife suspects her husband, or the husband his wife; he neglects his person or his food, or broods over some subject of vexation and anxiety. At length some manifest delusion or some overt act indicates that reason is upset. Some morbid propensity or appetite is developed, or some insane delusion is adopted, corresponding in some way with the previous character of the individual, the exciting cause of the disease, or the more prominent subject of interest for the time.

In mania there is a complete perversion of the character, dispositions, and habits; in monomania the perversion most commonly corresponds in some measure with the previous character, or temperament, or habits of the individual,—the delusion or morbid propensity which is adopted takes its character from the prevailing train of thought preceding the attack, or from the nature of the exciting cause of the disease.

Melancholia attacks chiefly persons of a bilious or melancholic temperament; monomania of self-esteem and pride, those of a sanguine temperament,—the temperament modifying the form of the disease. If the moral causes are of a depressing kind, the delusions and propensities developed assume a corresponding character, and the patient imagines he is ruined—that his soul is lost—that he is about to be executed or poisoned. If the immediate moral causes are of an exciting kind, the resulting insanity is of a more or less gay and elevated character; the patient imagines he has succeeded to large estates or titles, or that he is a person of great power or genius.

The nature of the delusions of the monomaniac is often determined by the more exciting public topics of the day, and their character bears the date of the times. Among the ancients the monomaniacs were prophets and prophetesses, hermaphrodites, or changed in sex, or converted into pigs, foxes, or wolves. In the middle ages the dark superstitions of the times produced many wizards and witches, demonomaniacs and vampires. In modern times it has been observed, that during the first Napoleon's time there were many Napoleons in the public asylums of France. There were many queens in our asylums, and many pretenders to the crown, when our present sovereign ascended the throne. Later years have seen many victims of electrical machines and electricity, of mesmerism, and, lastly, of spirit-rapping, in our hospitals. Instead of furies and demons now pursuing the victims of morbid fears, as of old, it is now the fear of the law, of justice, of prison, of the police, or of being hanged.

Insanity in some of its forms is highly contagious; or rather the imitative faculty, or the strong sympathies existing between morbidly predisposed minds, is so great, that the publication of any revolting murder by a homicidal maniac, or the perpetration of some remarkable suicide, immediately produces a host of imitators. When H. Cornier committed child murder, Esquirol was consulted by many families of distinction, and of all ranks, whose daughters were seized with a similar morbid impulse. When a female committed suicide by leaping from the summit of the Monument, she had so many imitators that it was found necessary to guard the balcony at the top by a cage.

1. *Melancholia.*—The subjects of melancholia are generally of a spare habit of body, have dark hair and eyes, and a brown or sallow complexion. The expression of the countenance is fixed and immovable,—a tension of the features expressive of fear, grief, or despair; the eyes are fixed on the ground, or watching surrounding persons with sidelong and suspicious glances. The pulse is commonly slow and feeble, but hard and thrilling. The skin is dry and hot, with the exception of the hands and feet, which are bedewed with cold perspiration. The sleep is interrupted, short, irregular, and often agitated by dreams and sudden starts. The tongue is white and loaded, the breath offensive, and the bowels constipated. Melancholics are extremely sensitive to external impressions, alarmed by the slightest cause, irritable and impatient of interference. They convert everything into a new source of distress, and dwell without ceasing upon their misery, their fears, and their sufferings. Melancholia may exist as a variety of *moral* insanity, or insanity without delirium. There may be no false belief, no delusion, but a simple abstract gloom, deep and rooted melancholy, an inexplicable but hopeless feeling of wretchedness, a loathing of everything, even of life itself, and an anxious craving for death. The suicidal impulse in some such cases is remarkably strong, and attempts to commit self-destruction are made by every conceivable method, and with the utmost craft and deliberation. In most cases of melancholia, however, there exists some delusion, which seems to be the focus round which the feelings of gloom and horror concentrate. Such is the common belief in eternal perdition; that the person himself has been the cause of ruin and misery to his family; that he has brought judgments and punishment upon the whole human family; or that he has committed the unpardonable sin, and is already suffering the pains of lost souls.

Monomania of fear.

2. Very closely allied to these cases of melancholia are those described as *monomania of fear*, in which the characteristic feature is a constant dread and apprehension of some coming evil,—a foreboding of misery,—a terror of

being hurried away, of being poisoned, or executed, or burnt alive, or of some dreadful and unavoidable calamity.

Such delusions are sometimes not incompatible with the discharge of the ordinary duties of life. The celebrated Robert Brown, at the time when all the powers of his mind were in full exercise, believed that his soul was annihilated, and that instinct only, common to him and the brute creation, was left to him. Cowper the poet believed that he alone of all human beings was excluded from the vicarious merits of our Saviour's sufferings.

Suicidal mania.

3. These two varieties of monomania are those most frequently accompanied by a disposition to commit suicide. Sometimes this impulse is a morbid impulse, unaccompanied by any delusion,—a loathing of life, a craving for death, an irresistible impulse to commit self-destruction. This must be regarded as another form of moral insanity, and may be termed *suicidal mania.* Most frequently, however, this fatal propensity seems to originate in the dreadful delusions of the patient, in the despair arising from the conviction of being ruined or eternally lost, or in morbid apprehension of some approaching and horrible calamity.
